As soon as the season would permit, out-of-door exercise was advised. The entire summer was spent in driving and walking. Increasing in health and strength, already before midsummer one crutch was thrown away. October 1st a cane took the place of the crutches. She occasionally complains of neuralgia when the wind is east. Menstruation perfectly regular. Walks any distance by the aid of a cane.

REPORT ON PROGRESS IN THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M. D.

KAIRINE AND ANTIPYRINE.

BOTH of these antipyretics are quite new; the former, kairine, was noticed at some length in last year's report, in which it was suggested that "it will be found to have too many disadvantages to ever become very popular, although as the forerunner of a more perfect antipyretic which we may look for in the near future it is of interest." The more perfect antipyretic has already been discovered, and appears under the name antipyrine; it is undoubtedly superior to kairine, and although it will in its turn give place to some new rival, it merits attention. But first a word about the action of kairine on the blood may be permitted.

M. Loyd[2] has recently published the results of his experiments in this direction, which are of interest in suggesting an explanation of its antipyretic action as well as of certain toxic symptoms which were observed in some cases where kairine was given in large doses. Under its influence he finds that the blood absorbs oxygen less readily, and this suggests the reason for the cyanosis and other similar phenomena which sometimes occur after the administration of this remedy.

Dr. Filehne[3] has introduced to the profession an alkaloid prepared by Dr. Ludwig Knorr, and named antipyrine on account of its antithermal properties. It is a white crystalline powder, readily soluble in water, without disagreeable taste, and, as a rule, is easily borne by the stomach, notwithstanding the fact that

[2] Practitioner, July, 1884; Progrès Medicale, May 10, 1884

[3] Zeitschrift für klinische Medicine, Liebenter, Band 641.

rather large doses must be given. The administration of five or six grammes, given at intervals of an hour in two-gramme doses, can reduce the temperature from that of a high fever to about the normal, and without any untoward symptoms except occasional vomiting. It may also be used subcutaneously. The duration of its action varies with different individuals; generally in from seven to nine hours, often eighteen or even twenty hours, after the beginning of its action, the temperature gradually rises. The rise in temperature is never accompanied by a chill, as is the case with kairine, and is generally without perspiration. The maximum antithermal effect is reached in from three to five hours. With children one half to two thirds of the above dose will suffice; patients with phthisis and such as are much emaciated should also have a smaller dose.

The frequency of the pulse drops in proportion to the fall of temperature, except in the later stages. The urine is free from albumen.

On page 162 of this journal may be found an account of the experience of several eminent clinicians with this substance, and still further favorable reports are given by Von Noorden.[1] He has observed that when the perspiration which accompanies the fall of temperature is prevented, by a dose of agaricine, no disturbance of the antithermal action of antipyrine is caused, so that this group of antipyretics probably do not act by causing a loss of heat through evaporation from the surface of the body. In his trials of the drug vomiting has seldom been caused; this may be avoided by using it subcutaneously in rather smaller doses. He makes the important suggestion that the heart and pulse should be carefully watched, particularly when large doses are given.

In children it has been used by Penzoldt and Sartorius[2] in twenty-one cases, twelve of which were sick with pneumonia, and the others with catarrhal pneumonia, erysipelas, scarlatina, and diphtheria. The children took the drug readily in orange syrup, vomiting was caused in only a few cases, and in two it was necessary to give up its use by the mouth and administer it per rectum.

No especial change in the pulse was observed, although it seems to have been somewhat less frequent with the fall in temperature. Their verdict is that antipyrine is a very suitable drug with which to lower the temperature in children, and by appropriate doses it is diminished several degrees in a few hours. The patients were more cheerful or slept quietly, and they were better at night under its influence.

The proper beginning dose is as many decigrammes as the child is years old, given an hour apart for three hours; per rectum from three to six times as much may be used.

After it has been continued some time the system seems to become somewhat accustomed to it.

ANTIPYRETICS.

An account of what seem to have been elaborate experiments on the antipyretic treatment published in *Virchow's Archiv* by Dr. Sassetzky, of St. Petersburg, is given in the *Lancet* of January 5th, and will be of interest in this connection. They consist chiefly of a study of the assimilative functions and tissue changes occurring in fevers, especially as shown by the elimination of nitrogen.

[1] Berliner klinische Wochenschrift, No 30, 1884.
[2] Berliner klinische Wochenschrift, No. 32.

The research was undertaken with the view of testing the effects of treatment directed to control the fever, and more particularly the cold bath treatment. Care was taken not only to analyze the urine but also the fæces in order to be able to estimate the elimination of nitrogen; at the same time the amount of nitrogenous food taken was carefully noted. In this way it was hoped to determine how far assimilation is interfered with, and what proportion of the nitrogen eliminated could be attributed to tissue metabolism.

Observations were made upon cases of typhus fever, relapsing fever, and pneumonia, typhoid fever being excluded. Analyses were made during three definite periods — during the antipyretic treatment, while the fever was left uncontrolled, and after the febrile disturbance had passed away.

In nine cases the antipyretic agent was the cold bath (72.5° F.) for fifteen minutes four times a day; in four it was quinine (two doses of ten grains each given in the evening); and in two it was salicylate of soda.

It was found that the cold bath invariably diminished the elimination of nitrogen, and that a similar but far less marked decrease occurred in cases treated by quinine and salicylate.

The writer would suggest that antipyrine offers an excellent opportunity to study the action of antipyretics, particularly as regards the elimination of nitrogen.

PARALDEHYD.

This new hypnotic is a modification of aldehyd, and presents itself in the form of a colorless, volatile liquid, which is soluble in eight parts of water. Its taste is less disagreeable than that of chloral. It may be given with syrup of orange or in the form of an emulsion.

Cervello,[3] after a careful study of its physiological action on animals, and after comparing its effects with those produced by chloral, has recommended it as a hypnotic. He observed that it produced a quiet sleep, unaccompanied by excitement or unpleasant after-effects, and with no disturbing action on the heart or respiration.

Clinically it has been used by several observers on quite a large number of patients.

Langreuter[4] has found it successful in eighty-two per cent. of more than two hundred trials in cases of mental or nervous diseases. An average dose of five or six grammes brought on sleep in from five to ten minutes, which continued at least two, and, as a rule, from five to seven hours.

Dr. Carl von Noorden[5] has given it to patients, having a variety of diseases, more than one hundred times with excellent results; in only two did it cause vomiting. He considers disease of the stomach a contra-indication for its use.

Two grammes of it cost one cent, according to Merck's price list; a dose would, therefore, be three cents, but in America the price is much higher.

In France[6] the accounts of its action are also very flattering.

Dr. C. Rank,[7] on the contrary, does not agree with many others who have used this substance. He complains of its extremely disagreeable taste and odor, and that it caused severe headache in many cases. In nervous sleeplessness and in delirium tremens it gave,

[7] Allgem. med. Central-Zeitung, July 26, 1884.

in his hands, satisfactory results, but in such cases as emphysema, bronchitis, cardiac diseases, acute rheumatism, and in various stages of tuberculosis the results were unfavorable or negative. As the drug is excreted largely by the lungs, the air in the vicinity of those who have taken it is strongly impregnated with its odor.

Notwithstanding some inconveniences it seems probable that this drug will be found to have sufficient advantages to make it a useful substitute for chloral when it is desired simply to overcome sleeplessness. It would seem to be a milder and safer hypnotic than chloral; and may prove a desirable addition to our limited number of hypnotics.

VINEGAR IN POST-PARTUM HÆMORRHAGE.

Some ten years ago Dr. Grigg [1] gave, by accident, a wineglassful of vinegar in a case of severe post-partum hæmorrhage. The uterus, which had previously been flaccid, contracted instantly, and the bleeding ceased. Since then he has used it successfully in another case, and has received favorable reports of its efficacy from his house-surgeons, and also from a number of midwives to whom he had recommended its trial. It is a remedy which may be readily procured, and is simple and harmless. He believes it to be better and more prompt in its action than ergot.

THE USES OF PEROXIDE OF HYDROGEN.[2]

This agent has been known and used in the arts for some time, and has also been used in medicine chiefly for its antiseptic properties, as it is one of the most potent destroyers of bacterial life. Its action on pus is rather remarkable. If a few drops of a ten per cent. solution be brought into contact with pus a brisk effervescence begins and continues until all the pus is completely destroyed. Its chief therapeutic value lies in its cleansing, antiseptic, and painless action upon foul ulcers. It is also useful in purulent ophthalmia, otorrhœa, gonorrhœa, etc., and as a mouth wash or gargle; it may also be mixed with glycerine and applied on absorbent cotton to the ulcerated cervix uteri. The account given of it is most flattering. It is colorless, odorless, and is not poisonous.

Dr. Steger [3] recognizes it as a valuable application for venereal sores, as it answers every purpose of the caustics and escharotics sometimes used in the treatment of these diseases, and at the same time it is painless. He has used this remedy in more than twenty cases of chancroid with success, and without using caustics or iodoform.

Reports of Societies.

CHICAGO MEDICAL SOCIETY.[4]

LISTON H. MONTGOMERY, M. D., SECRETARY.

THE TREATMENT OF ASIATIC CHOLERA IN SOUTHERN INDIA. — DISCUSSION.

DR. G. C. PAOLI had seen four cholera epidemics from 1834 to 1866, and since the latter date had passed through all the epidemics that had visited Chicago. Regarding the treatment he would add but a word or two, for all were familiar with it. Of all known remedies the best he knew was sugar of lead combined with opium to check the diarrhœa, in the proportion of two grains of the former to one fourth grain of the latter, given as one's judgment might dictate. In the stage of collapse it was useless to administer internal remedies, because the stomach would not absorb them. The blood is at this stage inspissated and would not flow, perhaps, and then the best external application was dry heat in the shape of warmed blankets. He did not believe in the germ theory as a cause of the disease. If germs existed he believed them to be innocent as causes of the disease.

DR. R. H. ENGERT asked the writer of the paper what his percentage of recoveries were in the cases he had treated.

DR. JOHN BARTLETT gave his experience briefly in treating 250 cases of cholera brought to a hospital in which he was attending physician; the per cent. of mortality was extraordinarily large. He expected he would be able to save the lives of one out of every two patients, but only one out of every six recovered. However, when they were brought to the hospital they were in the blue stage, or semi-collapsed, or partially cyanosed.

DR. J. H. ETHERIDGE stated that he believed the nervous system would in the future be proven to have more to do with the ultimate pathology of cholera than bacilli, which he regarded as an illusionary aspect of the disease, and that by using neurotic remedies at the first we will get at the gist of the trouble, — such remedies as relax the vaso-motor spasm of the abdominal circulation, preventing congestion of the venous system, and assist the vessels to correctly perform their physiological action, thus preventing their pouring watery portions of the blood into the intestinal canal. Dr. Chapman, of London, years ago applied ice bags to the spine for diarrhœa to enable the abdominal vaso-motor nerves to control the proper distribution of the blood.

DR. G. NEWKIRK asked if there was not some way by which the community could be educated through the newspapers so that the people could forestall epidemics? He had recently read in a Jewish newspaper that the Jews in France had not been afflicted with the cholera. If this were true he could not understand why they escaped its ravages, or how they were immune from it, unless it was because of their habits or better manner of dieting from instructions they obtained by reading Jewish journals.

DR. SCUDDER, in closing the discussion, said that the per cent. of recoveries varied from ten per cent. to eighty per cent., or, in other words, death occurred in twenty per cent. to ninety per cent. of the cases. In severe epidemics eighty per cent. to ninety per cent. of the cases resulted fatally. It would depend upon how early a case was seen, as to the chances of recovery. In thirty cases that he treated at one time by fumigating the premises with sulphur in addition to the other treatment, forty per cent. of them recovered, while in another shed in the relief camp with exactly the same conditions and treatment, except the fumigation process, where twenty cases were treated, eighty per cent. died.

In India the natives would not drink well water. Their religion had much to do with the frequent visi-

[4] Concluded from page 279.

tations of the cholera, for it taught them to drink only that which descended from heaven. This is true near Calcutta and Madras, where the water tanks are located near their temples of worship, which they regard as being sacred; they consider the surface water to be nearly as sacred as that which is stored in the tanks. An examination of this water showed it to be impregnated with microbes, or the germs of cholera. In contrast to the natives of India were those of China and Japan, where garbage and human offal are used to fructify the fields, and because they drink well water they are comparatively free from cholera. The Indians do not remove excrement and offal, or they do not cover it up, and when rain descends, which sometimes amounts to eight or ten inches during a single night, the surface water which they use is polluted. The speaker did not think that any benefits would be derived by people running away for a short distance from a district in which cholera was epidemic. General panic and fright predispose to the disease, and had much to do with its fatality. In India the poisoning of persons afflicted with cholera was frequent. Arsenic is given to a great extent, and the crime is largely undetected.

RHODE ISLAND MEDICAL SOCIETY.

THE usual quarterly meeting was held in Providence, September 18, 1884, the President, DR. OLIVER C. WIGGIN, in the chair.

PRESIDENT'S ADDRESS.

On opening the meeting the President regretted that he had been unable to procure any formal paper for the occasion. He hoped he was not assuming too much in reminding the Fellows that it was a duty they owed to each other, as implied in the covenant of their membership, to bring up the tithes out of their abundance, and thus cultivate a mutual respect and a broader fellowship. He thought it would be well if the Society would have a subject, or class of subjects, towards which to direct its thoughts, researches, and communications for the entire year. This would afford an opportunity for several essays and discussions upon the same subject. Such a course could but provoke much earnest and useful labor. As an initiatory experiment in this direction he would invite the presentation of essays on any of the zymotic diseases. It was hoped that essayists would confine themselves, in the treatment of their subjects, to the cause and prevention of the diseases under consideration, to the exclusion of their pathology and treatment. In other words, it was sought to direct the essays towards the somewhat prevailing tendency of medical research to "preventive medicine."

The President further alluded with satisfaction to the good work which the Society had accomplished in the last two years in effecting the enactment of the new medical examiner law. The law was drafted and ushered to the General Assembly by a committee appointed by the Society, and was enacted, with slight modifications, as it came from the committee. The success of this very important measure has been, on the whole, highly satisfactory. It was, moreover, flattering to the Fellows that out of twenty-four medical examiners in the State twenty of them were members of the Rhode Island Medical Society. It was believed, on the other hand, that the State had done itself an honor in launching the new law upon the public under the care of those who would direct it to the beneficent ends for which it was intended. It was believed, upon careful inquiry, that every appointment had fallen upon men who fully appreciated the importance and dignity of the office, and who would at once enter upon that special preparation so indispensable to the service. Attention was called to the fact that the library of the Society now afforded excellent facilities for medico-legal inquiry.

The President further urged the importance of establishing a pathological and anatomical cabinet, under the care of a special committee.

DR. S. OSCAR MYERS reported a case of

RUBBER CATHETER BROKEN OFF IN THE URETHRA,

and exhibited the specimens.

A man, aged sixty, had suffered several years with partial paralysis of the lower extremities. The sphincter of the bladder was also involved, and he was unable to retain urine more than an hour or two. Having found a rubber urinal unsatisfactory, he had recourse to self-catheterization at regular intervals, and had generally used a No. 10, American, soft rubber catheter, which was easily introduced but always withdrawn with some resistance. From long usage this instrument became brittle and cracked, — injuries which his frugal wife repaired with her needle. The catheter finally broke during withdrawal, leaving about five inches of its length in the bladder and urethra. The detached piece was seized and removed with straight uterine forceps.

Dr. Myers asked the best method of extracting a soft rubber catheter that had broken off or slipped entirely within the bladder.

DR. CASWELL recommended a small lithotrite to remove such bodies from the bladder. He had lately seen a case in which a soft catheter was sucked into the urethra. An ordinary dressing forceps caught it, and would be serviceable in such cases when the end of the catheter is anterior to the symphysis. Special urethral forceps, if deeper.

DR. BATCHELDER called attention to the frequency of these accidents with catheters, and thought they might be avoided somewhat by physicians more carefully specifying the instrument to be used and frequently inspecting it. He reported an analogous case. A middle-aged man who had been for some time accustomed to the use of a catheter consulted him for swelling and tenderness of the penis, a condition which was aggravated by unsuccessful attempts to pass the instrument. An obstruction was felt two inches from the meatus; the patient was put under ether, external urethrotomy performed, and a calculous mass weighing twenty-six grains removed.

DR. E. T. CASWELL read a paper on

PELVIC ABSCESS,

with special reference to a recent case.

Mrs. ——, aged forty-five, the mother of one child, seventeen years of age, came under treatment for persistent metrorrhagia. Dilatation of the cervix was undertaken for purposes of a more critical examination, and a sea-tangle tent was introduced one morning, followed by another in the evening, and larger carbolized sponge tents the next day, the process causing less discomfort than is usual. On examination nothing abnormal was found except two or three en

larged Nabothian glands, which were brushed over lightly with nitric acid.

Towards the end of the first week symptoms of peritonitis appeared. Variations in temperature and a hectic flush soon after indicated a forming abscess. Five weeks later a hard lump appeared in the left iliac region. This extended itself upwards, and could be traced to some depth in the pelvis, although a vaginal examination failed to reach it. Finally, ten weeks after the dilatation, fluctuation showed itself, and the abscess was opened under antiseptic precautions through the abdominal wall, about two inches above Poupart's ligament, and more than half a pint of healthy pus evacuated. A drainage tube was inserted, and the cavity syringed out with a solution of bichloride of mercury, one to 2000, and dressings saturated with the same solution applied. At each dressing for several days the cavity of the abscess was washed out. The washings were gradually diminished, and the tube removed in ten days. Convalescence was rapid.

It is fortunately seldom that the introduction of a tent is followed by such consequences, but these, and even worse, are within the experience of every man who has had much to do with uterine surgery. What determines the complete innocuousness of tents in one case and their potency for evil in another is a problem yet unsolved. In this case there had been no history of an antecedent cellulitis, or of anything that might contraindicate their use.

If from any cause an abscess forms in the pelvic cavity, the question arises, shall it be interfered with or shall it be allowed to take its course? If left to itself, the pus may find its exit either through the abdominal wall, through an opening into the intestines, into the ureters or bladder, possibly through the uterus itself, or, worst of all, and most to be dreaded, it may break and discharge into the peritoneal cavity. This last termination has been the strongest argument for surgical interference. To open the abdomen for the removal of a tumor, which can be disposed of in no other way, is, of course, the wisest and best course; but to open the abdomen to evacuate an abscess which, if left to itself, may find a perfectly safe exit is, at best, a hazardous proceeding. Every such case must be studied and decided by individual features.

DR. G. W. PORTER remarked, that usually there is comparatively little danger from the use of the first sponge tent; danger may follow the second or third tent, as sepsis is from absorption, which is more likely to follow prolonged dilatation. He recalled a case seen in consultation, in which, after removing a small tent, a soft polypus was twisted off, leaving a spot of absorption, and a second tent introduced. The result was septicæmia and death. Sponge tents should never be used as part of office practice, but only when the patient is in bed. If there has been no previous cellulitis their use is comparatively safe. If used carelessly they are a source of immense danger.

One difficulty attending the use of the laminaria tent is, that being of uniform diameter it may expand most where there is least pressure, that is, in the uterine cavity above the internal os, making its removal troublesome.

It is a good plan to make our own sponge tents. We thus have them of just the size wanted, are sure of proper antiseptic precautions, and can leave the surface rough. Such tents remain in the cervical canal much more surely than the smooth ones found in the shops.

SANITARY PRECAUTIONS AGAINST CHOLERA.

The PRESIDENT asked what sanitary precautions should be taken in view of the possible introduction of cholera next year?

DR. C. V. CHAPIN, Superintendent of Health, of Providence, replied that whatever theory be adopted concerning the nature of the disease, we look first to quarantine as an important means in preventing or delaying its progress, and maritime is much more successful than inland quarantine.

We cannot prevent the entrance of cholera, but we can prepare for it by securing pure soil, pure air, and pure water.

To prevent pollution of the soil a good system of sewerage is one of the essential conditions. The sewers in Providence are well built and in excellent condition, but there are two vital defects in the system: the houses are not all connected with them, and their outlet is not far enough from the heart of the city.

Where there are no sewers we have to deal with cess-pools and privy vaults, and the difficulty increases if there is an abundant water supply. In country places the disposal of sewage on the surface is less dangerous than cess-pools.

In Providence, in 1854, the hog-pens were found to be a nidus of cholera poison. All such nuisances should be abated. Streets and thoroughfares should be kept clean. All the conditions which pollute the soil will also pollute the air. Houses should be inspected, disinfected, and cleaned, and overcrowding prevented if possible.

The water supply should be from a source under control. Wells in thickly-settled places should be abandoned. Privy vaults should be systematically disinfected.

The bichloride of mercury, one to one thousand, is more efficacious as a disinfectant than any other practicable on a large scale.

DR. E. M. SNOW gave some interesting reminiscences of the outbreak of cholera in Providence in 1854. There were 159 deaths; 140 in two localities on the east side of the city, and nineteen on the west side. He noticed particularly the danger to washerwomen who washed clothing soiled by cholera patients. Such soiled clothes or bedding should be burned or thoroughly disinfected before washing.

As recommended by the Board of Censors, Drs. G. Edward Buxton, of Pawtucket, and Frank A. Payan, of Olneyville, were elected Fellows.

—Robert Barnes, writing from London to the *American Journal of Obstetrics* of some of the peculiarities in the professional relations of that metropolis, speaks of the contempt in which the practitioners of midwifery have been held by physicians and surgeons, and tells of a neat repartee once made thereupon by Robert Lee. At a full meeting of the Medical and Chirurgical Society the late Mr. Skey, bursting with an exultant sense of his surgical dignity, exclaimed, "Thank God, I know nothing of midwifery!" The rejoinder was prompt and crushing. "If," said the veteran obstetrist, "the gentleman who has just spoken is thankful for his ignorance, he has much to be thankful for!"

Medical and Surgical Journal.

No. 4 Park Street, Boston, Mass.

THE EXTENSION OF CHOLERA.

The two countries in Europe whose government officials, central and local, were the most prompt in proclaiming quarantine after the epidemic character of cholera in Southern France was realized were Italy and Spain, and not only was quarantine proclaimed in those countries but it was enforced, with all the vexatious and minute restrictions of a mediæval infatuation, and that not merely against ships or travelers from infected places but against all comers from whatsoever quarter.

It was not to be marveled at that Italy should take certain reasonable precautions against fugitives arriving direct by water or crowding over the Mt. Cenis railway and her French frontier from Marseilles and Toulon, especially as many of her own citizens of the poorer and less provident classes were at work in those towns. Nothing short of blind fear, however, could have suggested the extension of the same measures indiscriminately to all the routes of travel entering her northern frontier, to the St. Gothard and Brenner equally with the more western road.

Here is a description of the process from the reliable correspondent of a daily contemporary writing from Switzerland about August 1st: "At Chiasso on the St. Gothard road travelers are all cooped up together in a vile barrack, so closely packed, regardless of age, sex, and condition that the most common decencies of toilet are impossible. The food served out to them, and for which they have to pay dearly, is of the worst description, and for this there is no redress. Exercise is not permitted except for an hour a day in a paved court, under the superintendence of an official who watches the traveler carefully lest he should attempt an escape. The same thing prevails at Luino on Lago Maggiore, at Bardonneche, at Ventimiglia, and is carried on so entirely without discrimination or judgment that a man who has perhaps crossed the frontier half an hour, say, is detained on his return, cooped up with fugitives from cholera districts, thus perhaps making him a source of danger, which he certainly was not before."

Notwithstanding all this, the very first countries, after France, to develop cholera were Italy and Spain. In the former the first cases made their appearance in the last days of July, a man dying at Leghorn July 28th who had arrived from Marseilles and had fulfilled all the quarantine regulations; the latter country was invaded a little later. In Italy, Naples and Spezia have been especial sufferers, and in each place the especial reasons were not far to seek.

The first suspicious cases were reported from Naples August 24th, since which time more than 5000 people have died of cholera in that city alone, the highest daily mortality, 365 deaths, occurring on the 9th inst. Since this date there have been daily fluctuations, but the mortality is still very large, though declining, and the last daily toll of deaths reported as we write was 161, for September 22d. If one remembers that Naples has a population but little exceeding that of Boston, the weekly mortality-rate of which, from all causes, at the same season, may be set down at from 200 to 220, a realizing sense of what the daily deaths from cholera at Naples really mean may be arrived at.

The total number of deaths, something over 5000, is at least equal to that of all who have died in the whole of France up to the present time since the first case at Toulon, about June 17th, and that in one month. The deaths seem to have been about forty per cent. of those attacked, and it may with safety be reckoned that there have been about 13,000 cases.

This is, indeed, an experiment on a large scale, but whether anything more will be learned from it than was known before, to wit, that Naples has an insufficient water supply, bad drainage, and a very large, underfed, overcrowded population, packed in high tenements, abutting on narrow, dirty lanes, remains to be seen. The government at Rome is reported as having resolved to attack some of these conditions, but Naples has had many similar lessons before from plague, fever, and cholera, and we are reminded that the chapel vowed to their patron saint, Gennaro, by the stricken inhabitants, in 1527, was not begun until after a delay of eighty, and not finished for more than one hundred, years. It is to be feared that the Neapolitan ardor in hygiene will brook delay even more easily than their ardor in superstition.

Italy and Spain were the countries most strongly objecting to the adoption of the resolutions by the Vienna Cholera Conference of 1874 condemnatory of the old-fashioned perfunctory quarantine, but they can hardly hold that a detention of forty days would have availed them more than has one of twenty or ten, or would have stopped up any more of the holes in their sieve-like barricade. The countries which cry the loudest for the strictest quarantines are like those individuals who spasmodically and tempestuously tell their beads, most conscious of secret sins.

The royal visit of King Humbert to Naples has shown us that a king can be at once courageous and intelligent, and emphasizes the theory, based upon many observations, that the contagium of cholera may be safely faced, as a rule, if excluded from the digestive tract. It is reported that the food and drink consumed by the king during his sojourn in Naples were all forwarded from Rome. The priest and one of the guards accompanying the king are reported to have died. The royal exposure, however, was none the less admirable because arranged for on a scientific basis.

MILITIA AMBULANCE BEARER COMPANIES.

WAR is the intelligent but barbarous use of force in the settlement of national disputes, and while the humanitarian deplores its necessity he recognizes its occasional good results and attempts to mitigate resulting horrors. The first end to be gained is victory; that being accomplished, the care of the injured combatants should next engage attention. Modern warfare has reached a stage of perfection in which results are rapidly accomplished, and this is undoubtedly due to the development of arms, which can be used with rapidity and precision, the mobilization of troops, and their rapid and machine-like movements. Modern warfare has brought into use the railroads, telegraphs, massive steel cruisers, and new explosives. When we consider that with the improved Gatling and Nordenfelt ten-barrel guns a thousand shots can be fired in each minute, as was actually done in the Soudan, we see that a large number of combatants can be rapidly disabled. This increase in destructive power creates an increased necessity for means of caring for the injured. Unfortunately, however, military commanders have generally considered the care of the wounded as a minor consideration, and only in recent years has it dawned upon such officers that the certainty of good care in the event of misfortune develops in men an "esprit de corps" second only to the accomplishment of victories. Again, the certainty of good care and attention, in case of injury, softens the anxiety of those who part with their loved ones for the national defense. This home feeling forms the foundation of the moral support on which commanders at times lean so heavily, and without which supplies of men and material to carry on their campaigns would be wanting. The lamentable failure of men to receive proper medical care in the Crimea early drew attention to the defects of the old system of caring for the disabled. It was only when Letterman in our civil war developed gradually an ambulance system (which at the close of the war was quite effective) that the necessity for sure, rapid, and effective treatment and transportation of injured combatants was properly appreciated. Many will remember the heart-rending tales of the needless suffering in transportation inflicted on our soldiers in the early part of the civil war. Needless, because this exigency of warfare should have been foreseen and provided for. As late in the war as February 24, 1863, a bill to organize an ambulance corps failed to pass the United States Senate, and it was rejected owing to its being considered by the committee "an impracticable measure at this time," "this time" being the especial moment at which its need was greatest.

It is rather surprising that a matter of such vital importance as the care and transportation of wounded combatants should have been delegated until within a few years to a body of untrained and hence unskilled, unqualified band-men and stragglers.

That a military commander should leave his second greatest object to be achieved in the hands of an ill-defined body of men, a failure in whom to perform their duty brings disaster and defeat upon him and disgrace in the eyes of all civilized people from his failure to provide for the ordinary exigencies of warfare, is past comprehension. Major-General George B. McClellan appreciated the necessity for an ambulance corps. In a letter dated February 21, 1863, addressed to Henry I. Bowditch, M. D., in answer to the question, "Should the men in the ambulance corps be detailed soldiers, taken from time to time from the ranks, or should they be men enlisted for the purpose and taught their especial duties?" General McClellan answered as follows: "There are many self-evident objections to the system of taking men temporarily from the ranks for this duty; they need instructions in their peculiar functions as well as the ordinary discipline, and should have distinctive uniforms. I am of the opinion that men should be enlisted especially for duty in the ambulance corps." Dr. Bowditch asked also the following question: "Do you think the establishment of such a corps would increase the number of non-combatants?" McClellan's answer is: "I think it would decrease the number of non-combatants, especially during battles."

In recent campaigns no such flagrant neglect can be recorded. The rapid advance which Wolseley made into the interior of Egypt, owing to the retreat of Arabi Pasha, demonstrated that had he been encumbered with sick and wounded, or had not his medical department been completely organized, his campaign would have been seriously impeded and possibly failed. Even as it was, a long investigation of the "break-down" of the medical department ensued on his return. This so-called break-down was probably due to the non-elasticity of the department in its inability to conform itself to the strained situation from lack of proper training. Although the histories of campaigns will always essentially differ, by reason of the ever-varying circumstances which surround them, a lesson has been taught that in future a successful army must be one that can move rapidly and strike quick and decisive blows, and an army whose fighting men must wait to care for the wounded does not meet the requirement.

One hundred and thirty-three thousand dollars were expended in 1883 by the Commonwealth of Massachusetts for her volunteer militia; this amount keeps in existence and instructs a body of men who would in case of need quell insurrections and repel invasions. Infantry, artillery, and cavalry are the three branches developed, and of late years special attention has been paid to heavy artillery, rifle practice, and signaling, but owing to a variety of causes no ambulance corps has ever been established. It is generally considered that a militia should be a school of instruction for the men, and the public expect the development of a nucleus from which can grow, in case of necessity, an effective body of soldiers. Now it is a well-worn axiom that familiarity and experience with any work are necessary for its best accomplishment. Therefore the training of an ambulance bearer corps should form part of the duty of the volunteer militia. Of small numbers, but properly instructed and drilled, this body would form a unit from which might spring in time of need

a service of the greatest importance. Volunteer ambulance bearer corps have recently been instituted at the various hospitals throughout England, and the corps as they now exist are formed of medical students. These corps occupy the same position to the volunteer militia that the hospital bearer corps do to the regular army. At Aldershot, a few weeks since, a detail of a hundred men, acting as wounded soldiers, were searched for at night, after a supposed battle, by the aid of an electric light carried by a bearer company of the army hospital corps, with all the paraphernalia of transports complete. The application of the electric light was a distinct success, the necessary dressings of the wounded being performed with accuracy and dispatch.

An attempt was made at one of the recent annual encampments of the Massachusetts militia to instruct the men in the treatment of emergencies; owing, however, to a variety of causes the trial was a failure. This was due, in a great measure, to the amount of tactical instruction and drill required of the men. The topics considered were of general interest, but the men showed a lack of appreciation by reason of these conflicting duties.

It was also found impracticable after "retreat," the men requiring amusement at that time rather than instruction and hard work. Now, while a general knowledge of the principles of sanitary science, as taught German officers, is of importance, we feel that in time of war the rapid treatment of wounded combatants demands the training of brave and intelligent men for this important work. We hope that there will soon be an ambulance bearer corps connected with the various State militias, under the control of the surgeon-general of the State. A company should be connected with each brigade, under the direction of the medical director, and this company should be composed of enlisted men, having the proper number of sergeants, corporals, and privates. A number of such a bearer corps should be medical students, as it is self-evident that by the discipline of such a service they would be better fitted to act after graduation as medical officers of the volunteer militia.

ALCOHOLIC DISEASE IN CHILDREN.

One of the most painfully interesting communications at the recent meeting of the British Medical Association, says the *Lancet* (September 6th), was by Dr. T. M. Madden, Physician to the Hospital for Sick Children, Dublin, on Alcoholism in Childhood and Youth. Dr. Madden testified that many such cases came under his view. He gave particulars of a case of marked delirium tremens in a boy aged eight. His mother was a drunkard, and he, at the age of six, on discovering a secreted bottle of whiskey, showed the hereditary tendency to follow her example. Before admission into the hospital with delirium tremens he had obtained access to a bottle of port wine and almost emptied it. He nearly died from coma, and, delirium tremens supervening, he was taken to the hospital. Boils followed, and he remained weak in mind and body for nearly a month. He was then sent to a reformatory and recovered. A second case of juvenile alcoholism in a newsboy, aged eight, was the son of a drunken mother. He was sent for his mother's whiskey, and was rewarded with a sip. Dr. Barlow, of London, followed with some startling facts as to infantile alcoholism, gathered from his experience in the Children's Hospital, Ormond Street. He had seen the evil effects of small doses of gin given to babies at the breast for flatulence. He had also found it customary to give quite young children among the poorer classes a daily quantity of beer. He had seen two or three cases of well-marked typical cirrhosis, with a little ascites, from this cause. He detailed one very striking case — the child of an apparently healthy mother, able to suckle it, and in fair circumstances. From six months old the child was given a tablespoonful of beer twice daily, and from nine months old a teaspoonful of gin in as much water daily. The child died, and was found to have one of the most typically hob-nailed livers Dr. Barlow had seen. Dr. Barlow properly added that he had seen hob-nailed liver in children where it was not possible to have alcohol. Dr. B. O'Connor bore similar testimony. These are appalling facts, which give great force to the warning of Dr. Madden and Dr. Barlow as to the responsibility of prescribing alcohol to children.

On the other hand the unperverted taste of children is often the physician's surest guide for the administration or cutting off of alcohol in wasting or debilitating diseases. Few practitioners, probably, have not had occasion to wonder at the strange instinct which leads children to refuse stimulants which they had previously been taking in large amounts, and with evident relish; in such cases the result of immediate discontinuance almost invariably justifies the obedience to the instinct.

MEDICAL NOTES.

— In the latest number of the *Centralblatt für die medicinischen Wissenschaften* to reach us, under date of September 6th, the editors, Professors Kronecker and Senator, write these appreciative words of their deceased associate, Julius Cohnheim: —

"On the 15th of August, at midnight, Dr. Julius Cohnheim, the regular professor of general pathology and pathological anatomy in the University of Leipzig, quietly and painlessly passed away, in consequence of an attack of palpitation, after long sufferings, in the forty-fifth year of his age. Attacks of gout, the first of which visited him fifteen years ago, gave rise to progressively increasing disease of the kidneys, in consequence of which his heart had become hypertrophied to a very unusual degree. His great vitality and the devoted care of his noble wife and affectionate physician had averted for two years the constantly impending danger of dissolution. Now that the care is over the remembrance of our great loss remains. His intellectual powers were still at their height when sick-

ness disabled his body. This is not the place to express an estimate of Cohnheim as a student. He has, in his manual of general pathology, erected a monument which shall long be an inspiration to the investigator striving for his high aims. Simple and vigorous as was his truth-loving character is his style of expression. His joyousness of nature was never disturbed by harsh or even malicious criticism of his investigations in untrodden fields. He openly acknowledged errors into which he had been led. He gladly accepted the coöperation of others. He communicated his clear views without reserve to his fellow-workers. Hence he collected a large circle of pupils, in whom his thoughts and his methods will continue to live. His rich mind took intelligent part in every intellectual movement, and enjoyed intercourse with friends of the most different professional circles. He has been associated with this periodical from its origin, as founder, collaborator, and in the years 1866–1868 as editor. A true friend has gone from us. His spirit still lives with us."

— The correspondent of the *Lancet* (September 6th), writing from Italy, has a good word to say of the tour of King Humbert II. through the cholera-stricken communes. "Two years ago," remarks the writer, "during the disastrous floods in the Venetian territory; last year, after the calamitous earthquake in the island of Ischia; this year, in the choleraic centres of Piedmont — the King has endeared himself to his subjects by his faithful reproduction of that heroic self-abnegation and paternal solicitude on their behalf which they love to associate with his sire, the '*Re galantuomo*.' Modestly attired in a low, round hat, with walking-stick in hand, accompanied by the Prime Minister Depritis, by his adjutant, and by the local physicians, he has been visiting every hospital where the cholera patients are housed, going from bed to bed, inquiring into each individual case, taking note of the treatment and its results, addressing genial words of encouragement to the more desponding sufferers, and leaving substantial donations to each institution on his departure. Praiseworthy as such conduct would be in a country like ours, it is trebly so in Italy, where ignorance, superstition, and centuries of insanitary prejudice have added tenfold to the miseries and the dangers of the cholera epidemic."

— The Bearing of Electric Lighting on Health was the subject of an essay by Mr. R. E. Crompton and a conference at the recent Health Exhibition, as we learn from the *Popular Science Monthly*. Mr. Crompton held that the conditions of health were not so good in any kind of artificial light as in daylight. Even the electric light, diffused, is deficient in intensity and inferior to daylight. All artificial lights except the electric contaminate the air. At the twelve-candle standard, coal-gas vitiates 348, paraffine oil 484, composite candles about 650, and tallow candles 933 cubic feet of air per hour, but the electric light none. The amount of heat produced in the same time by the same lights is represented respectively by the numbers 279, 362, 383, 505, and 14. The criticism of the glare of the electric light is not just; we are not supposed to look at it. The real test is the intensity of the diffused light. The steadiness of the incandescent electric light gives it a great advantage over all others, and the arc-lights are also being made more steady. The eyesight of the men in the British General Post Office has been greatly improved since the electric lights were introduced. Other advantages of the electric light are the greater pleasure it gives, its greater convenience, and its absolute safety.

— Dr. Mercier, of the West Pennsylvania Hospital, Pittsburg, relates (*Philadelphia Medical Reporter*, May 31st) the case of a black poodle, a year old, and weighing about fifteen pounds, from which the spleen was removed in 1875. It was gently detached from surrounding parts, leaving only a narrow pedicle, which was divided after being tied with silk ligatures. These were cut off short and allowed to remain in the wound. The incision of the abdomen was closed by six silver sutures. These were removed after two weeks, and the dog continued a house pet for nine years, exhibiting no change in disposition, and acquiring about double its former weight. He was a good house dog, and in every way a healthy anima[1]. He died suddenly after exposure to severe cold, January, 1884, the only lesion discernible being severe enteritis affecting the lower part of the small intestine. There was not the slightest trace of the spleen, nothing to denote its former locality, no remains of the pedicle, nor anything to show that nature had made the slightest attempt at restitution.

— The *Medical Times*, speaking of a recent discussion at the meeting of the British Dental Association at Edinburgh on the fee for operations, and the absurd system of giving advice, where no operation was indicated, for nothing, says: "The question thus raised is, however, capable of wider application than to dentists only. In all the departments of our profession the public are willing to pay, or at any rate do pay, at a very much higher rate for manual dexterity than for advice pure and simple. Indeed, the inconsistency and absurdity is much more obvious in the case of medicine and surgery than it is in dentistry. Thus a man will pay two guineas for a consultation on which the whole future of his life depends, for instance, whether he is to leave the country on account of a supposed or real delicacy at his chest, and a hundred guineas for the removal of an eye that is hopelessly lost. So long as the profession by its silence virtually expresses its approval of the doctrine implied by this scale of fees as to the relative value of scientific discrimination in the one case, and the extremely slender manipulative dexterity required in the other, we must not be surprised if the public fail to take a more enlightened view."

— Baron Tennyson has received a well-deserved rebuke by Dr. Moxon in a paper recently read by him on the late Dr. Hilton Fagge, and published in the English journals. The poet, in a volume of ballads published in 1880, gave expression to libelous remarks regarding the medical profession, whereupon Dr. Moxon comments as follows: —

"Fagge's greatness as a physician appeared in his always kind and sympathetic and Christian treatment of the sick poor. It is easy for poets to put their own denials of Christ into other people's mouths, and then as fashionable authors to spread them about on drawing-room tables. It is convenient to be able to work off your baser sentiments in a false character; you yourself then appear pure by contrast with your own creations. But if one's solemn every-day duty is spent face to face and eye to eye with the sorrowing and suffering poor, one wonders how even a poet-laureate could be capable of thinking the matter of those loathsome lines of this new peer. I wonder is he yet ashamed of them? What footing has this poet aristocrat on any grounds of charity that justifies him in putting his blasphemous sentences into the mouth of the child he supposes? Let him go into a children's hospital, and see how far the poor sick little ones think as vilely as he of the kind-hearted doctor, whose only sorrow is that his best help to his little patients too often proves ineffectual. Fagge was physician to the Evelina Hospital for Sick Children. His sympathies were not with grandeur and the House of Lords."

— Professor Mallet, M. D., LL. D., Ph. D., has been appointed to the chair of chemistry in Jefferson College as successor to the late Professor Rogers.

— Among the new methods recommended for the use of iodoform we note a plaster made by incorporating with the ingredients employed in making ordinary adhesive plaster twenty per cent. of iodoform. This plaster, if applied directly to the previously cleaned surface, and in the case of slight burns and small wounds, is said to be very healing.

Correspondence.

SUCCESSFUL TREATMENT OF SNAKE-BITE BY THE EXPLOSIVE CAUTERY.

Mr. Editor, — The recent reports of fatal cases of snake-bite induce me to invite attention to a method adopted and found successful in the case of a soldier of troop I, Fourth Cavalry, at Camp Supply, Indian Territory, in the fall of 1878.

The patient was struck upon the dorsum of third phalanx of the forefinger while engaged in gathering wild grapes.

He reached me very soon after the occurrence, probably not more than ten minutes. The surface about the fang puncture was slightly moistened and as much gunpowder as could be retained placed on it. The powder was then ignited, the wound scarified, and powder again ignited upon it; then a light linseed poultice sprinkled with tinct. opii. completed the dressing. Brandy was administered freely, and the patient soon fell asleep. The finger and hand were considerably swollen and discolored. There was slight nausea and depression, all of which soon passed off, and the man recovered.

I had learned of a case occurring among the Indians a short time before this, which was successfully treated by the explosive cautery, followed by a poultice of the chewed root of a species of chenopodium. No stimulants. In this case, that of a young squaw, the wound was on the leg.

This cautery is rapid, painless, and thorough, and if quickly applied appears to afford the best chances for recovery.

Very truly yours,

T. G. Wilcox, U. S. A.

Washington Barracks, D. C.,
September 19, 1884.

Miscellany.

THE PHYSIOLOGICAL ASPECT OF MESMERISM.

The *Popular Science Monthly* for October contains an article by J. N. Langley, F. R. S., on the above subject. The writings of Dr. Braid and others from the time of the original achievements of Mesmer down to the present time are drawn upon, and an attempt is made to account on physiological grounds for the phenomena of hypnotism. The results of hypnotism in the lower animals are compared with those in man, and it is shown that in the former the possibility of exciting certain parts of the nervous system while the others remain oblivious is less than in man. Regarding the therapeutic possibilities of hypnotism the author says: —

"There can, I think, be no doubt that mesmerism may help, and sometimes cure, persons suffering from certain diseases of the nervous system. It is not in our power to make any accurate statement of the way in which this is brought about; but, since disease may be the result of either an over activity of or an under activity of any part of the central nervous system, it is reasonable to suppose that a beneficial effect will follow the employment of a method which allows us to diminish or increase these activities as we will. This is a side of the question which is of the greatest interest both to physicians and to physiologists — to physiologists, since it bears directly upon the problem of the influence of the nervous system on nutrition. There is good reason to believe that, by directing attention strongly to any particular part of the body, the nutritive state of that part of the body may be altered. The determination of the actual way in which this is brought about is full of difficulties, but the following way is at least theoretically possible: It may be that the nerve-centres connected with the tissue in question are made unusually active, and that they send out nerve-impulses of a trophic nature, that is, impulses which directly control the nutrition of the tissue. The alteration in the tissue caused by its changed nutritive state — its changed *metabolism* — may conceivably be either beneficial or detrimental to the whole organism; it may give rise to a diseased state, or get rid of an existing one.

"The modern miracles of healing, wrought in persons in a state of religious enthusiasm, offer a field for investigating this problem; the field, however, is a particularly bad one, and chiefly because so many people concerned regard any careful examination of the subject as impious. But in mesmerized persons it seems probable that such investigations could be made on a fairly satisfactory basis. Men when mesmerized gradually lose remembrance of those things which they remember when they are awake, but not infrequently other things are remembered which are forgotten in

the waking state.[1] This is normally the case with a person who has been previously and recently mesmerized. He may then remember little else than what took place in the corresponding stage of his previous mesmerization. In a certain state, then, an event or a command will produce in the central nervous system those changes which are necessary for the event or the command to be remembered later, without ever rising to consciousness in the waking condition. Thus, a command to do a particular thing, given to a subject in this mesmeric stage, may be carried out when he awakes, although he is quite unconscious why he does it. We may say that such an act is one of unconscious memory. But it is, I think, something more than this. The subject is usually uneasy and preoccupied until the thing is done; he is, to a greater or less extent, unable to fix his attention on other things; he is, in fact, in a state of unconscious attention to an unconscious memory. This brings us to our point. It suggests that if a subject, in a certain stage of mesmerization, be told that in a few days a sore will appear upon his hand, or, conversely, that a sore already there will disappear, the conditions which accompany conscious expectation and attention will, to a certain degree, be established, and the tropic influence of the nervous system on the tissues may be tested in a manner which puts the experiment fairly within the control of the observer, and, to a certain degree, excludes imposture. Such an experiment has obviously some drawbacks: it would probably only succeed, if it succeeded at all, with a person whose nervous system was in a state of unstable equilibrium; and it can hardly be expected that the effects would be so striking as when conscious expectation is also concerned. Still, observations of this kind are well worth attention, on account of the medical, the physiological, and the psychological issues involved in the results."

The author sums up the results of his observations into the following outline of a theory, which he says is only provisional: —

"The primary condition of mesmerism is an inhibition of a particular mode of activity of the cortex of the brain, in consequence of which the will can no longer be made effective.

"This inhibition may be brought about by nervous impulses coming from certain sensory nerves, as those of sight, touch, hearing.

"It may also be brought about by impulses or changes arising in the cortex itself.

"The inhibited cortex, and probably also inhibited lower centres of the brain, send out inhibitory impulses to all other parts of the central nervous system, so that the mesmerized man or animal gradually passes into a state of torpor, or even of complete anæsthesia.

"The phenomena of the excitable stage of mesmerism are proximately determined by the possibility of exciting any particular centre alone, without exciting at the same time other centres by which its activity is normally controlled. In lower animals this stage is less marked in consequence of a greater interdependence of the various parts of the central nervous system."

[1] A case is recorded by Braid of a woman who, during natural somnambulism — which is almost identical with a state that can be produced by mesmerism — could repeat correctly long passages from the Hebrew Bible, and from books in other languages, although she had never studied any of these languages, and was quite ignorant of them when she was awake. At length, however, it was discovered that she had learned the passages when she was a girl by hearing a clergyman with whom she lived read them out aloud.

REPORT OF A REMARKABLE CASE OF COUGH.

DR. MACCOY reports in the *Medical News* (August 30th) an unusual case of irritative cough, as follows: —

"Mrs. S., aged forty, resident of Philadelphia, the mother of one healthy child, was first seen in December, 1882. At this time she was suffering from an almost continuous, exhausting, irritative cough, accompanied by violent fits of gagging, which had defied all treatment, and which had continued for several years. The patient was very thin of flesh, and her face much care-worn. She stated that her attacks of cough often lasted for hours, and were frequently accompanied by the fits of gagging, which came on after the cough had continued for a short time. Sometimes, after ascending the stairs, gagging would follow, and soon render her helpless. Her debility was so marked after one of these paroxysms that she frequently had to go to bed, and was compelled to remain there for some hours. Between the attacks of coughing and gagging she was rendered most miserable, and was completely debarred from social engagements.

"Examination showed no pulmonary disease. Inspection of fauces revealed marked cicatrices involving most of the posterior pharyngeal wall; extending well down the throat. Laryngoscopic examination at once made manifest the cause of her attacks. On a line with the superior margin of the arytenoidal portion of the larynx, on the posterior wall of the pharynx, was a horizontal cicatricial band extending well across the pharynx, about one eighth of an inch in diameter, the ends of which spread out in a fan-shaped manner, the fibres being lost in the tissues on each side. This band was so placed that the free edge of the epiglottis was touched by it while rising and falling, and readily explained the cause of the cough. The gagging was brought about by interference with the free action of the vertical and circular muscular fibres of the pharynx, as well as by impingement of the free edge of the epiglottis.

"The *specific* action (undoubtedly the cause of the destructive change) had long since ceased. While there was no direct history of syphilis, there was a history of a severe attack of ulcerative disease many years before, which she states her physician called diphtheria. No lesions of syphilis excepting those found in the throat were visible.

"The treatment consisted in dividing the cicatricial band with the galvano-cautery knife *vertically*, and dilatation. The first operation was not attended by perfect success owing to the incision being too near the median line. A few weeks after the first operation a second incision was made on the left side much longer and deeper than the first one. This effort was eminently successful. For six months there was absolutely no return of cough and gagging. Quite recently there has been some return of her attacks from neglect to keep up the dilatation. Another operation of multiple incisions was made a few months ago, which again completely relieved her. With occasional dilatation it is probable that the result will be perfect, but without it contraction will certainly occur in time (as is so well known), and the result will not be so satisfactory as it now is."

The author speaks favorably of the adaptability of the galvano-cautery knife for the relief of this condition, in fact is unable to see how the operation could have been performed so safely and so well by any other method.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 6, 1884.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 3127 (no report from Buffalo): under five years of age, 1549; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 927, diarrhœal diseases 535, consumption 351, lung diseases 158, diphtheria and croup 103, typhoid fever 91, whooping-cough 59, malarial fevers 45, scarlet fever 31, cerebro-spinal meningitis 27, measles 21, puerperal fever six, erysipelas five, small-pox three, yellow fever one. From *whooping-cough*, New York 16, Brooklyn 14, Boston 12, Chicago five, Philadelphia four, Baltimore three, St. Louis, New Orleans, Pittsburg, Milwaukee, and Cambridge one each. From *malarial fevers*, New Orleans 22, Brooklyn 10, St. Louis five, New York four, Baltimore two, Philadelphia and Charleston one each. From *scarlet fever*, New York eight, Philadelphia four, Chicago, District of Columbia, and Milwaukee three each, Boston and Baltimore two each, St. Louis, Cincinnati, New Orleans, Pittsburg, Lowell, and Lawrence one each. From *cerebro-spinal meningitis*, Philadelphia 15, St. Louis three, New York two, Chicago, Cincinnati, District of Columbia, Charleston, Lowell, Worcester, and Holyoke one each. From *measles*, New York and Chicago eight each, Brooklyn two, Pittsburg, Milwaukee, and Fall River one each. From *puerperal fever*, New York, Brooklyn, St. Louis, Providence, Cambridge, and Holyoke one each. From *erysipelas*, Brooklyn two, Baltimore, Charleston, and Brookline one each. From *small-pox*, New Orleans two, Philadelphia one.

Cases reported in Boston: scarlet fever 26, typhoid fever 14, and diphtheria 12.

In 112 cities and towns of Massachusetts, with an estimated population of 1,356,032 (estimated population of the State 1,955,104), the total death-rate for the week was 22.10 against 19.75 and 22.24 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending August 23d, the death-rate was 25.6. Deaths reported 4293: infants under one year 1670. Deaths in London 1579: acute diseases of the respiratory organs (London) 157, diarrhœal diseases 995, whooping-cough 77, measles 71, scarlet fever 67, fever 53, diphtheria 24, small-pox (London 21, Sunderland three, Liverpool, Sheffield, and Birkenhead one each) 27. The death-rates ranged from 17.4 in Bristol to 39.3 in Preston; Birmingham 32.5; Bradford 21.9; Leeds 32.8; Liverpool 30.5; Manchester 31.5; London 20.5; Nottingham 32.5; Sheffield 34.2. In Edinburgh 14.6; Glasgow 26.6; Dublin 30.3.

For the week ending August 16th, in Berlin there were 845 deaths. Diarrhœal diseases 103, consumption 82, diphtheria 32, whooping-cough 17, measles four, scarlet fever four. Death-rate for the week, 35.3.

For the week ending August 23d, in the Swiss cities there were 56 deaths from diarrhœal diseases, consumption 41, typhoid fever nine, lung diseases five, diphtheria five, whooping-cough three, small-pox, measles, and puerperal fever each one. The death-rates were, at Geneva 17.3; Zurich 17.7; Basle 17; Berne 20.

For the week ending August 14th, in Paris, there were 42 deaths from typhoid fever, diphtheria and croup 36, diarrhœal diseases 272, whooping-cough 13. The death-rate was 27.8.

The meteorological record for the week ending September 6th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date. August–Sept., 1884.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM SEPTEMBER 13, 1884, TO SEPTEMBER 19, 1884.

CALDWELL, D. G., major and surgeon. Granted leave of absence for one month and twenty days, to commence about October 15, 1884. S. O. 95, headquarters Division of the Missouri, August 16, 1884.

CRONKHITE, HENRY M., captain and assistant surgeon. From Department of the Platte to Department of the Missouri.

TAYLOR, ARTHUR W., first lieutenant and assistant surgeon. From Department of the Missouri to Department of the Platte. Paragraph 1, S. O. 215, A. G. O., September 13, 1884.

MACAULEY, C. N. B., first lieutenant and assistant surgeon. Assigned to duty at Fort Sisseton, D. T. S. O. 99, Department of Dakota, September 6, 1884.

OBITUARY.

DIED, — In Boston, September 17, 1884, Howard Franklin Damon, M. D., M. M. S. S., aged fifty-two years five months.

AMERICAN GYNECOLOGICAL SOCIETY. — Programme of the Ninth Annual Meeting, to be held at the Palmer House, Chicago, Tuesday, Wednesday, and Thursday, September 30, and October 1, and 2, 1884. Physicians are cordially invited to attend the sessions.

First Day, Tuesday, September 30th. Morning Session at ten o'clock. Roll Call, Reception of Guests, etc. Papers: (1.) Moot Points in Regard to Inversion of the Uterus, by Dr. John C. Reeve, of Dayton, O. (2.) Foreign Bodies in the Abdomen after Laparotomy, by Dr. Henry P. C. Wilson, of Baltimore. (3.) Abdominal Section: its Value and Range of Application, by Dr. C. D. Palmer, of Cincinnati. Adjournment at one P. M.

Afternoon Session at three o'clock. (4.) The Hygiene of Pregnancy, by Dr. Samuel C. Busey, of Washington. (5.) Rapid Dilatation of the Cervical Canal, by Dr. William Goodell, of Philadelphia. (6.) Cervical Fibroids as a Cause of Dystocia, and their Removal by Vaginal Enucleation, by Dr. Paul F. Mundé, of New York. Adjournment at five P. M.

Second Day, Wednesday, October 1st. Morning Session at ten o'clock. (7.) The President's Address. The Present Aspect of the Puerperal Diseases, by Dr. Albert H. Smith, of Philadelphia. (8.) A Further Report upon Extra-uterine Pregnancy, embodying Six Cases, by Dr. T. Gaillard Thomas, of New York. (9.) A Case of Tubal Pregnancy, with Rupture of the Sac, by Dr. R. B. Maury, of Memphis. Adjournment at one P. M.

Afternoon Session at three o'clock. (10.) The Limits of Vaginal Hysterectomy for Cancer, by Dr. Paul F. Mundé, of New York. (11.) Some Remarks on the Occipito-posterior Position in Vertex Labors, with an Analysis of Thirty-five Cases, by Dr. Edward Warren Sawyer, of Chicago. (12.) A Rare and Fatal Form of Sepsis without Symptoms, by Dr. George J. Engelmann, of St. Louis. Adjournment at five P. M.

Business Meeting at 8.30 o'clock, with closed doors. Report of the Treasurer and Auditing Committee. Action on proposed amendments to the Constitution and By-laws. Election of officers for 1884–85. Nominations for honorary and active fellowship by the Council, and balloting on the same. Report of the Committee on Publication. Adjournment of the Business Meeting.

Third Day, Thursday, October 2d. Morning Session at ten o'clock. (13.) The Physiognomy of the Vulva as a Sequence of Anal Disease, and the Cause or Sustaining Cause of Uterine Disease, by Dr. Isaac E. Taylor, of New York. (14.) The Early History of the Treatment of Vesico-vaginal Fistule in the United States, and the Statistics of the Several Modes of Operating, by Dr. Nathan Bozeman, of New York. (15.) Periodical Symptoms in Uterine Disease, by Dr. George J. Engelmann, of St. Louis. Adjournment at one P. M.

Afternoon Session at three o'clock. (16.) Contributions to the Topographical and Sectional Anatomy of the Female Pelvis, by Dr. David Berry Hart, of Edinburgh. To be read by Dr. Alexander J. C. Skene, of Brooklyn. (17.) Fibro-myomata and Fibro-cystic Myomata of the Uterus: their Diagnosis, Prognosis, Pathology, and Treatment, with Cases and Specimens, by Dr. R. Stansbury Sutton, of Pittsburg. (18.) On the Ring of Bandl, by Dr. William T. Lusk, of New York. Adjournment at five P. M.

BOOKS AND PAMPHLETS RECEIVED. — Pathologie und Therapie der Frauen-Krankheiten, nach den in den Feriencursen gehaltenen Vorträgen bearbeitet von Dr. August Martin, Docent fur Gynäcologie an der Universität Berlin. Mit 164 Halzschnitten. Wien und Leipzig. Urban & Schwarzenberg. 1885.

Osteotomy and Osteoclasis for Deformities of the Lower Extremities. By Charles T. Poore, M. D. New York: D. Appleton & Co. 1884.

Atlas of Female Pelvic Anatomy. By D. Berry Hart, M. D., F. R. C. P. E. New York: D. Appleton & Co. 1884.

Catalogue of the National University, Law Department, Medical Department, Dental Department: Washington, D. C. 1884–85.

Later Antiseptics in Private Surgical Practice. By Dr. Powell, Edgar, Ont. Read before the Ontario Medical Association. (Reprint.)

Removal of a Piece of Iron from the Vitreous Chamber by means of the Magnetic Needle. By Julian J. Chisholm, M. D. (Reprint.) Baltimore. 1884.

A System of Human Anatomy, including its Medical and Surgical Relations. By Harrison Allen, M. D. Section VI. Organs of Sense, of Digestion, and Genito-Urinary Organs. Philadelphia: Henry C. Lea's Son & Co. 1883.

Grundriss der Operativen Geburtshilfe für praktische Arzte und Studirende. Von Dr. Friedrich Schauta, O. O. Professor der Geburtshilfe und Gynecologie an der Universität Innsbruk. Mit 30 Holzschnitten. Wein und Leipzig: Urban & Schwatzenberg. 1885.

Henke's Atlas of Surgical Anatomy. A Series of Plates Illustrating the Application of Anatomy to Medicine and Surgery. Translated and edited by W. A. Rothacker, M. D. Cincinnati: A. E. Wilde & Co.

Original Articles.

THE EXTERNAL APPEARANCES OF PISTOL-SHOT WOUNDS.

BY D. B. N. FISH, M. D., OF AMHERST.

As by far the greater number of gun-shot wounds that come to the notice of the medical examiner are those caused by pistols or revolvers, I shall confine myself almost exclusively to a consideration of the wounds made by these "weapons of luxury," as they have been so fitly termed.

I have drawn freely from the works of Casper, Ogston, Taylor, Woodman and Tidy, Hofmann, Briand and Chaudé, and others, at times even using their language without always indicating the source from which it is drawn.

When called to view the dead body of a person supposed to have come to his death from gun-shot wounds many questions will present themselves to the medical examiner that may depend for their solution entirely upon the evidence found upon the body itself. He will have to decide whether the death has been accidental, homicidal, or suicidal. If homicidal, it may be important to determine at what distance, with what weapon, and from what direction the fatal shot has been fired.

The trajectory of the bullet through the organic tissues is subject to many and unforeseen variations; it may happen — as it has to so astute an observer as Casper — that the ball cannot be found even at the autopsy, and one may be forced to form an opinion from the external appearances alone of these pistol-shot wounds.

Let us remember at the outset that "death makes disappear many of the phenomena of color, and brings about a relaxation of the parts which may change the dimensions of the wounds, or the situation of the wounded organs."

These wounds, under the force of ever varying conditions, are very different in appearance and extent; their appearances are far from having an absolute value, and "their significance is largely dependent upon the experience and acuteness of the observer."

The resistance of the air, modified, perhaps, by prevailing winds, the difference in length and calibre of the barrel of the weapon, the difference in the quality of its workmanship and even in its condition by reason of proper care or the want of it, the quantity and quality of the powder used, the shape and weight of the missile, all tend to make the problems more difficult of solution.

The wound made by a ball penetrating the body may present an appearance like that of Braun's "cuts of a lancet," or his "mere scratch," which had healed by first intention; or like Hofmann's wound of the scalp, "so slight, that having escaped detection at the first examination, it was only revealed at the autopsy;" it may be a smooth, round opening, — large or small, — an oval wound, or a valvular one; it may have a starred or a serrated outline, or may be irregular and torn giving to an otherwise simple wound a frightful appearance.

"In general, a bullet preserving its integrity, impinging at ordinary range and at a right angle upon any portion of the body well covered with soft tissues and not unnaturally put upon the stretch, leaves, as it passes through the skin, an opening more or less regularly rounded in form, often, perhaps, a little less in diameter than the missile, with its edges inverted and livid in hue, due to the contusion and to the discoloration from the burned powder carried upon the missile. A cylindro-conoidal ball will probably cause an irregularly outlined opening either stellate or slit like with serrated edges. If the ball has traversed the body, the wound of exit may closely resemble that of entrance, but is usually larger and more irregular, with everted edges, bearing few evidences of contusion, but often showing greater loss of substance." [2]

"The wound of entrance is large and irregular when a ball strikes near the extremity of its range."

When a spherical bullet is fired from some distance and has lost but little of its momentum it usually makes a round, well-defined opening, while a conical ball frequently causes a linear incision; this is true especially of revolver-shots, which may produce wounds, very insignificant, similar to knife-cuts. The aperture is made with comparatively little bruising or tearing, and the resilient tissues close upon its track.

As a rule the entrance will be round only when the ball strikes at right angles; it will be oval or valvular when it strikes obliquely, but it sometimes happens that a conical ball from an inferior weapon, even when fired at right angles to the body, strikes wholly or partly upon its side according to the distance from which it is fired, thus always making an oval wound. A revolver in my possession at any distance beyond eighteen inches throws a ball flat-wise; within this distance it strikes partly upon its side, never upon its apex.

"Fired at a moderate distance but so near as to traverse the body, the orifice of entrance will be well-defined, round, or oval according to circumstances, — the skin slightly depressed, — the edges presenting a faintly bruised appearance; but the surrounding parts are neither blackened nor burnt, and they do not present any marks of bleeding. In these cases the orifice of exit is large and irregular, the skin lacerated but free from any appearance of blackening or burning; it is generally three or four times as large as the entrance orifice." [3]

In regard to the comparative size of these wounds of entrance and exit various and contrary opinions have been held by both surgical and medico-legal writers. On the one hand we have Woodman and Tidy claiming that "the exit wound is invariably the larger," while Casper as positively asserts that "the *wound of exit* is always smaller than the *wound of entrance*." It is probably safer to follow the middle path with those writers who teach that, in general: —

In shots fired from a distance the aperture of entrance will be the smaller. [As most gun-shot wounds observed by army surgeons are of this class, this may account for their unanimity of opinion that the orifice of entrance is the smaller.]

In shots from a short distance the two apertures will be alike.

When fired close to the body the wound of entrance will be the larger.

[1] Read at the meeting of the Massachusetts Medico-Legal Society, February 6, 1884.

[2] Otis, Med. and Surg. Hist. War of Rebellion, Surg., vol. iii., p. 711.

[3] Taylor's Principles and Practice of Medical Jurisprudence, i., p. 685.

It must be remembered that these are general rules, subject to many modifications.

Wounds of entrance made by revolvers and pistols will be smaller than those made by weapons of larger calibre; they will also probably be smaller when made by the cylindro-conoidal bullet, now so commonly used, than when made by a spherical ball. Small pocket revolvers, says Hofmann, give rise when they wound the skull only to a small opening whence radiate cracks in different directions.

The bleeding is usually slight, and when it occurs it is more commonly observed from the orifice of exit than from that of entrance.

As a rule the edges of the aperture of entrance will be inverted and those of exit everted, but Casper shows that this is not invariably so. He says: "If the part struck be very fat, the fat soon protrudes from the wound and it — the aperture of entrance — is found to have its edges swollen and anything but inverted. In other cases the putrefactive process causes the edges of both wounds — where two are present — to protrude, and so prevents their being recognized either as apertures of entrance or exit."

Hofmann says: "The assertion that the edges of the aperture of entrance are inverted and those of exit everted is correct in many cases, but not in all. In wounds from shots fired near by, the edges of the aperture of entrance are almost always everted when there happens to be bone beneath the wounded surface, because the gases of explosion are diffused between the skin and the bone beneath; the edges of the wound are crowded outward and may even be lacerated in this manner." [A statement which does not accord with my limited experience in such wounds.] "What proves this method of production of the ragged edges and rents," Hofmann goes on to say, "is this fact: that the edges of the aperture of entrance, whether this be irregular or rounded, are almost always undermined, and the subcutaneous tissues are blackened by powder to an extent corresponding to the parts undermined."

I hope to demonstrate further on that in pistol and revolver shots these gases of explosion, instead of passing with the ball through the skin, expend the greater part of their force upon the tissues at a point outside of the opening made by the ball. I can see that some particles of powder may cling to the ball and explode after passing through the skin. For, in firing a Colt's revolver at twenty-eight inches, several grains of powder passed, probably with the ball, through blotting paper and sprinkled the ash left after burning around the hole made by the ball in a second sheet of paper which was placed four inches behind the first one.

Medical Examiner S. D. Presbrey has furnished me the following notes of an interesting case which appear to demonstrate this possibility more clearly than do my own experiments: "An old man loaded a 'cut-off' musket with powder and shot, — both in large quantities, — put the muzzle to his stomach and fired. The cotton shirt had a hole, with burned edges, irregularly circular, four inches in diameter. Next, a thick woolen shirt had a ragged hole about one inch in diameter. Some few shot-holes to be noticed about the edges of this hole; edges scorched but not burned like cotton shirt. Next, a cotton-wool undershirt with a ragged hole similar to the one last described. Skin blackened with powder for a space of three inches square. In this blackened space were two *tears* through the skin, making together an opening somewhat like the letter T, its horizontal measuring two inches, its perpendicular, or rather, oblique, measuring one inch. The stomach with its appendages was hanging through a large hole in his back, blown out, apparently, by an explosion of powder within the body."

Here the burning powder had passed with the small shot through the cotton shirt, setting it on fire; through the other two shirts with little burning, — as woolen burns much less freely than cotton, — and then had exploded in part upon the body, leaving a blackened surface of larger dimensions than the opening made in the second and third shirts. It is probable that the remaining and by far the larger portion of the powder was carried within the body and caused the appearances of explosion.

Ogston says: "The edges of the entrance will be depressed and contused, the edges of the exit projecting and torn. The entrance will be dry and dark colored, the exit one raw and bloody. There will be loss of substance in the former case, but none in the latter."

The blackened and burned appearance of the edges of wounds of entrance has been variously explained. Otis, as already stated, ascribes it to the contusion and to the discoloration from the burned powder carried upon the missile. Taylor says it arises from the heat and flame of the gunpowder at the moment of explosion. Hofmann declares that it is due less to a burn than to a contusion and excoriation of the edges of the aperture of entrance, for it may be found, although less defined, in shots fired from a distance. Ogston asserts that it may result from a contusion of the wound causing an ecchymosis, or, when the piece is fired close by, from the burning of the powder.

On the other hand, Briand and Chaudé, alone of all the authorities consulted, speak of "the cauterization of the lips of the wound by the heated projectile." They quote Gosselin as describing "furrowed wounds, which present a surface, so to speak, cauterized by the projectile;" also, "cul-de-sac wounds — bleeding more freely, for the projectile, losing in proportion to its penetration of the tissues a notable amount of its momentum and heat, divides the tissues without cauterizing them." Such a heating of the projectile by the flame of the powder and by the friction of its passage seems impossible, as the time of exposure to such influences is too short. A rifle ball travels, on the average, about six hundred and sixty feet a second, and it takes only a few one hundredths of a second to burn over one hundred and fifty grains of powder. Capt. John E. Greer, now chief ordnance officer of the Department of Missouri, who was selected by the War Department, at the request of the Attorney General of New York, to make experiments in firing for use in the famous Billings murder trial in Saratoga County, has stated to me that at no range is the bullet heated sufficiently to burn the skin. His experiments were made with rifles, carbines, and revolvers on paper and on glass. [We probably shall not err greatly if we continue to speak of "a dose of cold lead."] Ogston has said that "as the blackened and scorched appearance of the edges of the entrance wound may be caused in more than one way, its presence or absence has to be accounted for by the history of the case, and is not found to be invariable in its occurrence. Where, as is frequently the fact, the blackening is due to ecchymosis being produced, the production or non-production of

this ecchymosis will account for the extent or absence of the blackening."

Dr. F. H. Hamilton relates the case of a soldier shot in the chest by a sentinel, in which the wound of exit was larger by one half than the wound of entrance, its edges not everted but looking discolored as though blackened by powder. This discoloration he found to be due to a slight extravasation of blood into the tissues under the skin.

"Small shot, fired at a distance," says Dr. Lachese, "of not over ten or twelve inches, may produce a round opening somewhat resembling that made by a bullet; from twelve to eighteen inches the opening was irregular and the borders were much lacerated; at thirty-six inches the central opening was entirely lost and the surface much covered with shot." Briand Chaudé say small shot begin to scatter at thirteen inches, while Dr. Lowe is said to have fired a new gun with the result of a round aperture resembling that of a bullet at a much greater distance than that given by Dr. Lachese.

Grains of powder may act as projectiles when fired at short distances, even penetrating the organs which they reach.

The wadding of a gun, paper pellets, a ball of wax or cork, may make holes like shot or like a bullet when fired from a gun with a large charge of powder at a distance of two or three yards.

The explosion of powder alone, without ball or wadding, is capable of causing very serious wounds, especially when fired into the mouth. When wadding has been used in like circumstances, it is known to have caused extensive laceration of the soft parts with fracture of the bones of the face and the base of the skull. So a pistol fired close to the abdomen, without a ball, has produced a fatal wound from the entrance of wadding alone. A pistol, loaded with powder and ball, may be fired with the muzzle pressed closely against the flesh without the ball touching the body. The weapon will either burst or recoil, and the bullet drop to the ground leaving only a contusion or a slightly contused wound, caused, not by the ball, but by the air within the weapon.

The aperture in the clothing made by the projectile is worthy of consideration. Dupuytren says it is always smaller than the ball; Taylor, that it is smaller when the clothing is of an elastic material. In comparing the size of the aperture and that of the ball, it must be remembered that the bullet may have struck upon its side and not upon its apex, also that the powder may have burned a portion of the clothing around the opening. Ogston says: "At the entrance of the ball, the tissue of whatever kind exhibits a more or less ragged and irregular opening along with loss of substance, while the injury to the stuff caused by the exit of the projectile is not so much a hole as a rent, either straight or shreddy, which will admit the tissue to be so replaced as readily to show that there has been no part of its texture destroyed or carried away. The opening made by the ball in entering is always smaller in the clothes than in the skin."

In firing at several thicknesses of cloth placed against a hard or a soft backing one may often get as many varieties of openings as there are layers of cloth.

Although foreign to the subject, it may be of interest to note the statement of Briand and Chaudé that "when the ball presses the clothing into the wound, taking several superimposed layers of clothing, we frequently find the layers in the inverse order in which we should expect them; for example, we find a shred of the shirt before that of the coat, which can be explained only by a rotary motion, if not forward at least laterally, of the projectile."

Before passing to the appearance of the powder marks let me call your attention to the following facts: —

"Two wounds nearly in a line may both be wounds of entrance, made by two distinct balls, both of which have lodged."

"The wound of entrance and of exit may be side by side, as when the bullet has passed around the body, or there may be only one wound through which the bullet has entered and also escaped."

"A plurality of openings does not necessarily imply a plurality of bullets, for one bullet has been known to make five wounds, — two of entrance and three of exit."

When the weapon has been fired at a distance, for ordinary pistols or revolvers, of probably not more than twelve to fourteen inches, the hair and skin may be singed, burned, or blackened from the burning powder; and at a distance, even for the larger weapons of this class, of probably not over forty-eight inches, unburned and partly burned particles of powder may be imbedded in the flesh.

These powder marks may, within certain limits, aid in estimating the distance at which the pistol has been fired, and the position in which it has been held. In some cases they may even show, with some degree of certainty, whether the weapon has been fired by one's own hand or by the hand of another.

They arise from the smoke, from the heat and flame of the burning gases, from partly burned powder, from the residue or ash of the wholly burned powder, and from partly burned and unburned grains of powder driven into the tissues.

The larger the charge of powder, the longer the barrel of the weapon, and the more finished its workmanship, the more marked will be these appearances; but with a large calibre and short barrel the powder marks will cover a greater extent of surface. Pistols will show these markings, and brandings of powder at greater distances than revolvers of the same calibre, for, having a continuous barrel, there is not that escape of the gases of explosion and of the unburned powder that occurs between the cylinder and the barrel of the revolver.

The most of my experiments have been made with revolvers, because it seems, in these days, when very fair revolvers can be bought for eighteen dollars a dozen, that by far the greater part of the murders and suicides are committed with revolvers using metallic cartridges.

Before detailing my own experiments, let me call your attention to what has been said of these marks of powder by others.

"Dr. Dumesnil," I quote from Hofmann, "found, in firing at pieces of white kid, that at thirteen centimetres (five inches) the tattooing and even the burning produced by the powder will remain, easily to be shown even after washing. It is very probable it will most always be the same" — upon white kid I suppose him to mean — "at twenty centimetres (7.87 inches). At thirty centimetres (11.8 inches) the traces diminished considerably; they nearly disappear at fifty centime-

tres (19.7 inches); and at eighty centimetres (31.5 inches) hardly a trace is to be seen.

"What disappears in the first place — passing from near shots to those fired at a distance — is the immediate action of the gases of explosion, which, even at short distances, are absent, and this in proportion as the charge is smaller; sooner for revolvers than for pistols, sooner for pistols than for guns.

"Tourdes, with a holster pistol" [the French holster or cavalry pistol is said to be of .45 of an inch calibre], "set on fire a piece of paper at one half a metre (19.7 inches), and we have observed burning of hair from a revolver nine millimetres in diameter (.35 of an inch calibre) fired from a distance of ten to fifteen centimetres (four to six inches). He also found an incrustation of grains of powder from a holster pistol at two metres (78.5 inches); from a great American revolver at one and one half metres (fifty-nine inches); from an ordinary revolver at forty centimetres (15.7 inches)."

Briand and Chaudé say: "Powder blackens the surroundings of the wound to an extent of several centimetres, and grains of powder incrust themselves in the circumference of the wound. Powder driven from a barrel burns on leaving it at a distance equal to the length of the barrel of the weapon; the burning wad is carried much further."

My own experiments do not accord with this statement, as a cheap revolver, with a four-inch length of barrel and cylinder, calibre .32 long, will burn cotton-batting at a distance of seven and one half feet, the burned spots appearing at a little distance from the entrance of the ball. It will scorch cotton cloth at a distance of five feet; bibulous paper at six feet. In certain other experiments the paper was set on fire at three feet, and several grains of powder had penetrated six layers of the paper; at thirty inches two holes were burned through the six thicknesses.

A Colt's revolver, old style, .32 calibre, six-inch barrel, with thirteen grains of "Duck powder, No. 4," burned cotton-batting at a spot two and one half inches from the entrance of the ball at eight feet. At two feet the batting was all on fire. Fired at seven feet it burned two holes the size of the ball through tissue paper. These holes were at some distance from and above the opening made by the bullet.

Resuming the extract from Briand and Chaudé, — "Experiments made with a holster pistol fired at hair on a sheet of paper have shown, at one metre, the paper blackened by some grains of powder; some had penetrated the paper. The hair had no trace of burning. Contour of holes made by the balls not blackened. At sixty-five to forty-eight centimetres (25.5 to 19 inches) the hair had not been burned nor the paper blackened at the entrance of the ball, but the black points and little holes made by the grains of powder were numerous. Ten shots at sixteen centimetres (6.3 inches), edges of hole extensively blackened to width of thirty-five to forty millimetres (1.38 to 1.57 inches). Several times the paper took fire. The hair always burned more or less completely."

Casper says: "These scorchings and brandings with powder only prove that the shot has not come from any great distance, that is, . . . from a distance not greater than from three to four feet."

The most explicit statement that I have seen appears in The New Dictionary of Medicine and Surgery, Paris, 1866, in which it is said that "The charring and burning of the vicinity of the wound, seen only at entrance, are always seen in shots at sixteen centimetres (6.3 inches); very nearly always from sixteen to thirty-two centimetres. Beyond this up to one metre there is no longer burning, but we may still find black grains incrusted around the wound. At sixteen centimetres paper takes fire frequently, hair always."

In regard to the blackening of the edges of the aperture of entrance in paper and cloth as well as in the flesh, experiment leads me to conclude that a part at least of this is due to the smut of the barrel — which even in the best revolvers becomes very great after repeated firing — and to the powder which clings to the ball because the latter is greased before firing. With a perfectly clean bullet fired from a clean and dry barrel the hole in the paper appeared free from any blackening; with a clean ball and an oiled but otherwise clean barrel there appeared slight smutting; with a greased ball, and especially after the piece had become foul, the blackening of the edges of the hole was very marked.

Nearly three years ago, while making some experiments in firing at short range, I noticed, in addition to the smutting of the paper by smoke, and to the marks of the partly burned and the unburned grains of powder distributed around the bullet hole, one spot, blacker and more burned than the rest. I found this was caused by the flame of the gases, by the burning powder, and by the residue, or ash, of the burned powder striking and resting upon this place. I also noticed that this burned and blackened spot held a most constant position directly above, or above and a little to one side of the bullet hole. Asking for the reason of this, I was told by an officer of the United States Ordnance Department that "as the velocity of the powder gases was greater than that of the ball, powder stains are found above rather than below the bullet hole." Thinking this might give some indication of the direction from which the shot was fired, I tried in later experiments to vary its position by firing at different angles, but with little or no effect.

Firing the pistol from either side, from above or from below the paper, the mark was still above the bullet hole, though its lower border sometimes came down to the level of the lower border of the opening made by the ball. After wasting much paper and ammunition it occurred to me to turn my pistol hammer down, that is, bottom side up. Now this spot appeared directly below the bullet hole, and I had a most pleasing solution of what had so long perplexed me.

I could put this spot on any spoke of the wheel of which the bullet hole represented the hub, simply by holding the pistol so that its hammer and sight were on a line with that spoke. Turning the pistol flat upon its side, with the hammer to the right, the spot appeared upon the right of the bullet hole; turning it hammer left, the mark was at the left of the hole.

The position of this burned or burned and blackened spot, varying constantly and varying exactly as the top or hammer of the pistol is turned on the long axis of its barrel, is due neither to the kind of weapon nor to the kind of ammunition used. Over two hundred experiments with seventeen different pistols and revolvers — rifled and smooth-bore of various calibres — fired with "loose ammunition," that is, powder and ball separate, or with rim-fire or centre-fire metallic cartridges, have failed to show any deviation from this result. It is due solely to the recoil of the muzzle of the weapon

This plate shows four shots made on dressed sheepskin from a Smith and Wesson new revolver, calibre 32, short, 6-inch range, with four positions of the hammer. The shot at the top was made with the hammer up, that at the bottom with the hammer down, those at the right and left sides with the hammer respectively right and left. Three fourths full size.

in the direction of its sight. When this recoil is prevented by fixing the weapon firmly in a vise the bullet hole will appear at or near the centre of the spot instead of at one side of it. This is well shown by the results of some seventy-two experiments kindly made for me, with the permission of the commanding officer of the National Armory at Springfield, Mass., by Mr. J. F. Cranston, an expert at the Armory. Of the seventy-two shots with three different weapons thirty-six were made with the pistols in a vise; each pistol was fired in four positions of the hammer — up, down, to the right, and to the left — at ranges of four, ten, and twelve inches; in no case did the mark appear at one side of the bullet hole. Of the thirty-six shots with the three weapons held in the same positions as before but held in the hand, at the same ranges, none that showed the mark plainly failed to show it at one side of the bullet hole and on a line with the hammer and sight.

It is barely possible that a pistol will be found in which the centre of gravity or of mass is so far forward on the line of its barrel that the recoil will be *downward* when held in the usual position for firing, but I am assured by gun dealers and manufacturers that, though rifles are sometimes so weighted at the muzzle, by brazing on a piece of iron, as to prevent the recoil upward, no pistols are made that do not thus recoil.

I have seen no allusion to the appearance and position of this spot in any work I have consulted, and have met no one who has ever noticed it.

I offer you, then, what I believe to be a new and almost infallible rule for determining the *position of the weapon*: —

Whenever this burned, or burned and smutted, spot is found, either upon the skin, the hair, or the clothing, at one side of the wound made by the bullet, by placing the muzzle of the weapon upon the wound so that the line of the hammer and sight will meet a line drawn from the centre of the wound through the centre of the spot of burning, or of burning and smutting, you will have the exact position of the weapon when it was fired. By position of the weapon I do not mean the distance at which it was fired, nor its angle to the body; the latter does not

seem to modify the rule I have given. As some revolvers of large calibre and short barrel will sometimes produce the greatest smutting opposite the point of greatest burning, the latter must be understood in such cases as the spot to which this rule is to be applied.

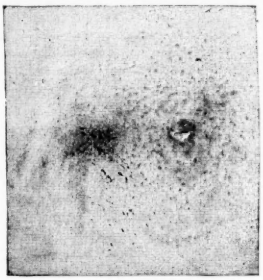
It will occur to you that there are many positions in which a suicide could not, or would not, hold a weapon for the purpose of shooting himself, because he could not hold it firmly enough to be sure of inflicting a mortal wound. If this *brand*, if I may so designate it, is found either upon the skin, the hair, or the clothing, showing one of these positions of the weapon impossible or improbable for a suicide, it is reasonably certain that the case is one of homicide and not of suicide. No suicide, for instance, would hold a pistol to either the side or back of his head with the hammer and sight pointing forward, or forward and downward, nor would he hold it to his heart with the hammer pointing downward and inward, or downward and outward; nor to his side pointing backward.

Moreover, if this *brand* is found in certain positions relative to the bullet wound, — such as forward and downward at the back of the head, or downward on the back, or downward and inward on the chest, — we may feel sure that the victim has not only been shot by another, but has been shot while lying down, or at least while in a reclining position; for no man who intends to shoot another holds his weapon upside down. While standing over the prostrate body he may easily fire so as to leave the *brand* of the powder upon any side of the bullet wound.

It is possible that in a struggle for the possession of a pistol it may be accidentally fired in one of these unnatural positions, but even then the very fact of its being held in such a position might be of importance in corroborating a claim that it was fired accidentally.

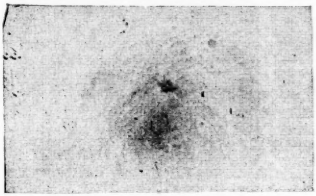
In testing for impossible or improbable positions of the weapon it should be cocked, as the hammer will thus interfere with positions that might otherwise appear possible.

Let me say here that among the illustrations of the rule given some will be found which apparently do not exactly conform to the given position of the hammer; this is due solely to the fact that in firing at such short range it is difficult to hold the weapon in just the position intended on account of the great sense of danger to the eyes from the rebounding grains of powder.



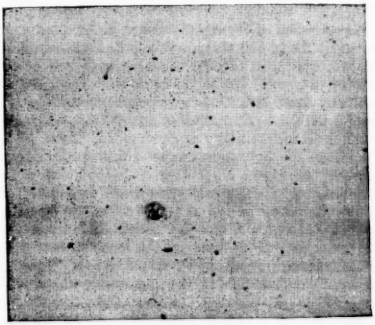
For the better preservation of these illustrations

Smith and Wesson 32, 6 in., hammer right.



Mr. Charles O. Lovell, of Lovell's Photographic Gallery, has generously enabled me to present herewith excellent photographs of some of the best of them. The illustrations which accompany this article are photographic reproductions of the original shots, reduced in size.

From the few experiments I have made, I believe



Union 38, 6 in. range, hammer left.

that the statement already quoted that "the charring and burning of the vicinity of the wound are always seen in shots at sixteen centimetres (6.3 inches), very nearly always from sixteen to thirty-two centimetres,"

Smith and Wesson 32, 8 in., hammer down.

will be found true in the case of shots fired from revolvers and pistols. One of .22 of an inch calibre, short, will probably show the powder brand plainly at four to six inches; a .32, short, at six to eight inches; a

Union 38, 36 inch range.

.38 at eight to ten inches; and a .44 at ten to twelve or thirteen inches. These figures are, of course, to be taken with a great deal of caution, as further observation may prove them to be erroneous.

As the distance of this *brand* — which always follows the line of the hammer and sight — from the entrance wound of the bullet will vary with the "kick" of the pistol and with the degree of firmness with which it is held, it is not probable that anything can be learned from this of the distance at which the shot has been fired. Neither have I been able, as yet, to draw any inference from the size of these powder marks as to the distance of the weapon.

Hair, unless it is wet or very oily, will show marks of burning at six inches with even the smaller revolvers and pistols; at eight to ten inches with a .38, and at twelve to thirteen inches with a long barreled .44 revolver.

The powder marks upon the clothing will, by comparison with the results of experiments upon the same material made with the weapon and with ammunition similar to that used, furnish the criteria by which the distance may be judged.

I have found that upon broadcloth the spot or *brand* can be distinguished with care at fourteen inches with a .44 revolver; at nine to twelve inches with a short barreled .38; at eight inches with a .32 long; and at six to eight inches with a .22 and .32 short.

White flannel cloth will be scorched and singed so as to define the position of the hammer at twelve inches with a .32 long; at fourteen inches with the same weapon this could not be detected.

On cotton cloth at twelve inches with a Smith and Wesson .32 short this powder brand was plainly visible even after vigorous rubbing; with a Robin Hood, fired with a .32 short cartridge, the scorching and smutting were much less marked, the latter being an inferior weapon with corroded barrel. At fourteen inches with a Colt's army .44 the *brand* was well defined.

It will be seen that I have placed the tissues upon which this powder brand will appear in the following order: first — at the longest range — cotton and woolen cloth; next, the skin; and last, the hair. It is possible that when the skin is moist it may not show the *brand* even when the hair is burned.

Of the marks left by the powder upon the skin there remains for consideration the tattooing caused by the unburned particles of powder driven into the flesh. The proportion of powder wasted varies with the character of the weapon and with the kind of powder used; even in metallic cartridges of the same size it varies with the degree of compression used in fixing the ball. For heavy artillery this waste is over sixty per cent., and from my own experiments I know it to be very great with small arms, especially with the cheaper revolvers. In revolvers a part of the unburned powder escapes between the cylinder and the barrel; in all fire-arms a part of it may never reach the target; of that which does reach it a part rebounds; how much will imbed itself in the skin is so much a matter of uncertainty that it is difficult to determine at what distance a given weapon will present a certain definite degree of tattooing of the skin.

After various and unsatisfactory experiments, none of which were upon the cadaver, I can do no better than to refer again to the statement found in The New Dictionary of Medicine and Surgery, that "beyond .32 centimetres (12.5 inches) up to one metre there is no longer burning, but we may still find black grains incrusted around the wound." Whether the tattooing of the skin can be produced at this distance by pistols and revolvers is not stated; it seems to me very doubtful except in the case of the larger weapons of this class, having a long barrel and carrying a heavy charge of powder.

Neither can I give any definite estimate of the extent of surface covered by the tattooing at different distances. It is possible that in some cases an approximate estimate can be formed by experiments similar to the following made with a weapon with which a homicide had been committed: —

A boy was shot in the forehead with a "Standard" revolver, calibre .32 long. The tattooing measured two inches in diameter. The hair was considerably burned directly above the wound. Experiments with this pistol, and with cartridges similar to the one used, showed that to produce the amount of burning of the hair the weapon must have been held at a distance of six inches or less. Firing at two thicknesses of blotting paper placed upon a hard backing, as many grains of powder perforated the first layer of paper at six inches as at four inches, but to reduce the diameter of the surface perforated to the two inches of the tattooing of the skin the pistol had to be fired at a distance of four inches.

The fact that in very near shots clothing may be set on fire by the deflagration of the powder or by the burning wad is worthy of consideration.

Ogston says: "As to the question of a fire-arm discharged close to the body setting fire to the clothes, and extending from this to any distance along the dress of the party, the French Academy decided after several experimental trials that though the clothing may be set on fire in this way, and the fire spread to a limited extent, yet the burning is usually confined to the borders of the orifice in the dress."

Briand and Chaudé state that "the burning clothing may burn the parts with which it is in contact, but the point of departure of the combustion is always upon one of the points of the circumference of the hole made by the ball. It will not burn to any great extent."

In my opinion it is safe to say that, usually, this combustion will start from that point at the edge of the hole in the clothing which is in a line with the hammer and sight of the weapon, although if this is below the entrance of the ball the greater amount of burning may be above, as the flame would naturally pass upward.

Experimenting upon a worn, light weight broadcloth coat, I have not been able to set it on fire at any range even up to two inches with a .38 revolver; at eight inches several fibres of a cotton pocket were burned in the track of the ball. At seven inches with a Robin Hood .32, the pocket was somewhat burned; at nine inches a .38 Union set on fire the padding of the coat in the track of the ball.

Firing at an old and well-worn box cover, which was stuffed with excelsior and cotton batting and covered with a sleazy curtain damask, a Hood .32, at twelve inches, charred the covering to an extent of one half inch in diameter about the bullet hole; at ten inches five holes were burned in the covering above the bullet hole; at nine inches cotton batting set on fire in the track of the ball; a Colt's .32, at nine inches, fired hammer up, with rifle powder, set fire to the cloth at the upper edge of the hole; this fire burned until it had to be put out to save the target; fired hammer down, it set fire to the lower edge; at eight inches neither Smith and

Wesson's revolver, .22, nor Stevens' pistol, same calibre, produced any burning; at seven inches the Hood, and at five inches the Smith and Wesson's, .22, would always start a vigorous fire.

Such a target as this will give a fine illustration of the fact that the greater part of the flame follows the line of the hammer and sight. After exposing the cotton batting by making an opening in the cloth covering, and then firing shots about the circumference of this opening, with the sight pointed towards it, one can see the burning powder strike in the opening and set fire to the batting, while if the sight is turned away from the opening the flame will very rarely touch it.

In experiments on cotton cloth, at ten inches, with a Hood, .32 short, powder passed with the ball through four thicknesses of cloth, and set fire to the cotton batting in the box cover. At five inches a Whitney, .32 long, set the edge of the hole on fire. A Smith and Wesson, .32 short, set the cloth on fire, and burned a hole six inches in diameter.

Flannel did not burn at five inches.

It has been said that a pistol fired into the mouth has set fire to the portion of the clothing touching the neck, and burned the neck, chest, and chin. The fire extended to the furniture of the room. Such a burning, starting from a point below the entrance of the bullet, would seem very improbable, and would lead to the suspicion that the fire originated from some source other than the discharge of the weapon.

Devergie has stated that at 2.25 inches the shot can set fire to the clothing at the level of the hole made by the bullet, and the combustion may spread to a certain extent.

How shall we decide from these traces left by the projectile and by the powder upon the body and upon the clothing whether death has resulted from accident, from suicide, or from homicide?

It will not be necessary to recapitulate the evidences left by the projectile.

Accidental pistol-shot wounds cannot be distinguished from homicidal wounds when both are inflicted from a distance. In shots fired near by, when one is known to have been shot by another, and to have been shot while standing, an unnatural position of the weapon, as shown by the relative location of the *brand*, will tend to corroborate a claim of accidental shooting. So if one is known to have shot himself an unnatural position of the weapon will show that the shot was probably accidental. The location of the wound and the course taken by the ball may also characterize the wound as accidental.

Homicidal wounds may be far or near, and will be determined by the exclusion of accident or suicide. If there are several wounds upon the body the case is probably one of murder, but both barrels of a two-barreled pistol, or even more barrels of a revolver, may be accidentally discharged at the same time. One bullet, as has been said, may make five wounds, and a would-be suicide has been known to fire five shots into his own body. Suicides generally shoot at the head, — often directing the pistol into the mouth, — less frequently at the heart or lungs, more rarely at the abdomen; yet they sometimes fire at the back of the head. "The murderer more often, unless furious with passion, fires at the back or side of his victim."

If the wound be upon such a part of the body that a suicide would not be likely to inflict it upon himself, or if, as has been stated, the relative location of the aperture of the bullet to the burning of the hair, or of the burning or burning and blackening of the skin or of the clothing, shows that the pistol has been held in a position unnatural for a suicide, it is probable that a homicide has been committed.

If there is entire absence of these scorchings and brandings of powder it will also generally prove that the case is homicidal, but it must be remembered that suicides sometimes arrange contrivances, by means of cords attached to the trigger of the weapon, for shooting themselves from a distance, and that certain "chemical powders" do not leave any stains of the powder.

Casper relates the case of a man who undoubtedly shot himself through the heart, but not a single grain of powder was found on the edges of the wound, the neck, or the face. A like instance has come under my own observation in which a suicide held a pistol, loaded with the ordinary metallic cartridge, so closely to the temple that the blood spurted into the barrel of the weapon, yet there was only the burning of the hair, and a stain of powder smoke just back of the wound, an illustration of the rule already given governing the location of the powder brand.

Briand and Chaudé say that in the case of a suicide by a revolver it is very rare that the muzzle of the weapon, directed towards the head, can be more than twenty centimetres (7.87 inches) distant. Though this distance can be easily increased to even twelve inches by any one with average length of the arms, yet just as the suicide would not hold a pistol in any unnatural position of the hammer and sight of the weapon lest he should fail to inflict a mortal wound, so he will not be likely to exceed this limit of twenty centimetres.

If the bullet is found, its weight should be ascertained, as thereby it may be possible to show that although deprived of a part of its substance it still weighs more than the ball apparently used.

The external appearances of every pistol-shot wound should be studied with care. Then by experiments with the same weapon, and with ammunition similar to that used, it may be possible to determine many points otherwise doubtful, but of vital importance.

I do not know of any substance that has been proved to offer resistance to the impact of powder similar to that presented by the living human skin, and I am forced to leave this for some more fortunate member of our Society to discover. I will, however, venture the opinion that we have in blotting paper, of average thickness, a material of value for comparative experiments. With a target of two thicknesses of this fastened against a board, the surface covered by projections or elevations and perforations appearing upon the posterior surface of the outer sheet, will, I am inclined to believe, show the extent of surface marked upon the skin by powder grains when fired from the same distance. It may also be found that the number of these projections or elevations together with the number of these perforations will be equal to the number of grains of powder imbedded in the skin.

My experiments have been made upon sheep skin, chamois skin, upon the skin of a young calf, and upon the skin of a living cat; also upon blotting paper of various thicknesses, rubber, cotton and woolen cloth.

SUMMARY. The *distance* at which a pistol-shot has been fired may be estimated by the following general rules: —

(1.) From a great distance the entrance wound will

usually be large and irregular; there will be absence of any great degree of lividity of its edges, and absence of the marks of powder. The wound of exit, if one is present, will usually be larger than the wound of entrance. At any distance the edges of wounds of entrance will usually be inverted, those of exit everted.

(2.) From a short distance the entrance and exit wounds will generally be nearly equal in size; the edges of the former will be blackened, and powder grains will be imbedded in the skin, but there will be absence of the scorchings and brandings of powder.

(3.) Close to the body the entrance wound will generally be larger than the exit. There will often be, in addition to the tattooing of the skin by unburned grains of powder, a mark or *brand* made by the flame of the gases and of the burning powder, by the soot of the partly burned powder, and by the residue or ash of the wholly burned powder. As a rule this *brand*, which may consist of a burning alone of the hair, the skin, or the clothing, or of a burning and blackening of the skin or clothing, will appear at one side of the bullet hole.

The *direction* of a shot will be shown in part by the trajectory of the ball, — a subject of which this paper does not treat, — and by the location of the wound of entrance. The character of the opening, whether rounded or oval, may give some indication of the angle at which the weapon has been held.

The *position of the weapon* (and whenever this term is used I wish to be understood to mean not its angle to or distance from the body, but the manner or position in which it is held; that is, whether it is held with its hammer and sight above the barrel, as in the usual position for firing, or with the hammer and sight below the barrel, as when the weapon is turned upside down, or in any other position of the hammer and sight relative to the barrel of the weapon) the *position of the weapon* is to be determined by the following rule: When the *brand* appears upon the hair, the skin, or the clothing at one side of the bullet hole, hold the weapon with its muzzle to the bullet hole so that the line of its hammer and sight will meet a line drawn from the centre of the bullet hole through the centre of the *brand*, and it will show the exact position of the weapon when fired.

This rule is deduced from the newly-discovered fact that, owing to the recoil of the muzzle of the weapon in the direction of its sight, this *brand*, when it appears at one side of the bullet hole, will appear upon that side which corresponds to the side of the hammer and sight in their position relative to the bore or barrel of the weapon. That is, if the weapon is held upside down the *brand* will appear below the bullet hole.

Accidental wounds are generally near wounds. When inflicted from a distance they cannot be distinguished from homicidal wounds. In shots fired near by, when a person is known to have been shot while standing, an unnatural position of the weapon, as shown by the location of the *brand*, will tend to corroborate a claim of accidental shooting. So, if one is known to have shot himself, an unnatural position of the weapon will show that the shot was probably accidental. The location of the wound and the course taken by the ball may also characterize the wound as accidental.

Homicidal wounds inflicted within the suicide limit have heretofore been distinguished from suicidal wounds alone by the location of the wound and by the uncertain evidence presented by the trajectory of the ball. When the location of the wound has been such that a person might easily have inflicted it upon himself there have been no means of determining from its character whether it was homicidal or suicidal. To aid in distinguishing between such wounds I offer the following rule: When the location of the *brand*, relative to the bullet hole, shows that the weapon has been held in a position of its hammer and sight impossible or improbable for a suicide it is probable that a murder has been committed. Certain relative locations of this *brand* may also indicate that the victim has been shot while in a reclining position.

Multiple wounds are usually homicidal, but may be either accidental or suicidal.

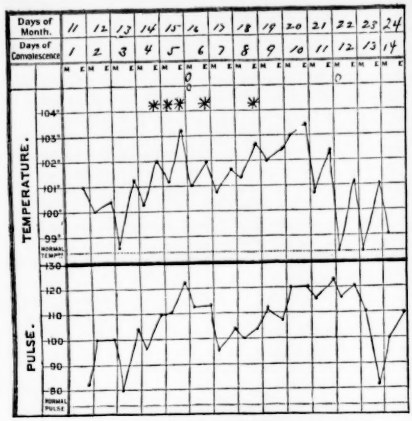
Shots fired beyond the usual suicide limit are probably homicidal.

Suicidal wounds. It is said that the suicide rarely holds the muzzle of his pistol at more than eight inches from the body. Suicides generally fire at the side or front of the head, next at the heart; they sometimes fire at the back of the head.

The distance from the body at which the weapon must be held to show the *brand* plainly is probably very nearly as follows: for small pistols and revolvers not over four to six inches; for large weapons of this class not over twelve to fourteen inches.

A CASE OF IMPETIGO HERPETIFORMIS.[1]

BY W. E. BOARDMAN, M. D.



MAGGIE D., single, twenty-six years of age, healthy, was confined at the Boston Lying-In Hospital March 11, 1884, after a labor which was normal in all respects, except that the placenta was extracted, expression having failed to cause its expulsion, and this procedure was followed by a slight hæmorrhage, which, however, was easily controlled.

March 14th, on account of the continued rise in temperature and pulse and offensive lochia, in spite of the usual care and treatment pursued at the hospital in all cases, she was given an intra-uterine injection of corrosive sublimate solution, one to 2000.

Upon the following day this was repeated, morning and evening, and each injection was followed by the insufflation of powdered iodoform within the uterus. The chart indicates a fall in the temperature and pulse beat on the succeeding day, but at evening the injection of the sublimate solution and the insufflation of iodoform were repeated, and the next day gave a morning record of temperature 100.8° F., pulse 95.

Upon the next day (the 18th) the record shows another rise, and the patient complained considerably of pain in the right side and below the breast. Nothing was discovered upon physical examination to explain this, and fearing a renewal of the septic process the former treatment was employed at evening of that day. Upon the following day the chart shows a slight rise, there was continued complaint of the pain in the right side, and an erythematous blush was observed between the thighs and upon the labia. March 20th these parts became the seat of a vesiculo-papular pustular eruption, and the erythema was noticed on the buttocks, upper thighs, lower abdomen, and breasts, rapidly becoming papular, and in some portions, particularly upon the breasts and adjacent portions of the trunk, vesic-

[1] Read before the Society for Medical Observation, May 5, 1884.

NOTE. — * indicates intra-uterine injection; *o* dejections.

ular and papular combined. This eruption gradually became confluent, and the parts first attacked began to scale. Upon the trunk the eruption became confluent and a serous effusion took place, commencing upon the lower abdomen, which raised the epidermis in the form of blebs, gradually increasing in size, flaccid and quickly ruptured, with the escape of a limpid, opaque fluid, non-irritant in character, and leaving the skin without ulceration, but oozing a thin fluid for a time, and of a deep rose-red color, desquamation following in large thin patches. Following essentially a similar order and appearance, the same process gradually invaded the whole surface by peripheral extension. The face, arms, and legs at the height of the inflammatory process presented a notable swelling and induration, which subsided after the rupture of the bullous sacs. In parts, especially upon the scalp, the fore-arms, hands, shins, and feet, the desquamation was largely in the form of thin, dry scales. The patient complained of some itching, which, however, was not excessive; of considerable pain, especially upon movement, where the disease was active. There was great prostration, necessitating frequent feeding and stimulation. The whole process occupied a period of about three weeks, though during the last week the patient was very comfortable, and convalescence rapidly ensued. Treatment: morphia for pain; oleate of zinc to the skin.

Dr. J. C. White very kindly visited the case on March 24th, the sixth day of the affection, and diagnosticated at once impetigo herpetiformis, or herpes impetiginiformis, and recommended the application of vaseline together with a wash of zinc and lime water.

The eruption, the history of which I have given, I fear, very imperfectly, belongs to a very limited series of cases, less than twenty in number, which have been observed and reported within the last twenty years, under various names, for example, herpes gestationis, herpes vegetans, herpes pyæmicus, herpes circinnatus bullosus, herpes impetiginiformis, impetigo herpetiformis, pemphigus pruriginosus, and by some, for example Gibert, it has been called a pemphigus. These various terms evidently have been suggested by different phases of the same disease. Hebra saw only five cases, four of which proved fatal under his observation, and the fifth died under a subsequent attack, according to the evidence of his son. In most of these cases the patients have been women, and the eruption occurred *before* confinement. In a few instances, notably in three of Hebra's cases and in mine, the affection was post partum. Autopsies were made in Hebra's four fatal cases, but they showed no certain causes of death.

Neumann studied the anatomy of some cases and was able to demonstrate a notable dilatation of the vessels, particularly of the veins and lymph channels, an abundant round-celled infiltration of the cutis, and a proliferation of the cells in the parenchyma of the sweat glands.

The ætiology of the disease remains obscure, as it is with pemphigus. Generally it is attributed to reflex nervous disturbances which have their origin in the pregnant state, a theory which is strongly supported by analogy in the case of various affections of the skin during the parturient period. In my case I was at first inclined to trace a connection between the skin affection and the septicæmia, and it occurred to me that possibly it may have been a phase of iodoform poisoning. It is for this reason that I have given a brief account of the patient prior to the appearance of the skin affection. I have been unable, however, to substantiate either of these ideas by any recorded experiences of others. On the other hand several cases have been observed, in men, at least cases which have been considered to be the same disease by competent observers, and while these would not negative the theory that it is dependent upon a neurosis, still they serve to complicate the subject of the ætiology. Syphilis, too, has been suggested as a prime cause. In my case there was no evidence, historical or otherwise, pointing to this, and it may be added that competent observers and investigators have failed to find any evidence sufficient to make this an ætiological factor in the development of the disease under consideration.

With regard to the nomenclature, the weight of evidence appears to favor the name impetigo herpetiformis, which, I believe, was first suggested by Hebra from a study of his cases; though those evidently differed in several points, as to their appearance and mode of development, from cases reported by other observers. The very common term herpes gestationis seems to be inappropriate, for it would appear that most, if not all, of the cases which have been included under the names previously narrated were properly instances of the same affection under different phases, and hence this term would be inapplicable for obvious reasons, while the name suggested by Professor Hebra will embrace all, premising that in most cases the impetiginous element has been a predominant one, while in others vesicles abound with a marked papular efflorescence, and in others, with which my case may be classed, a bullous or pemphigoid appearance of the eruption became, perhaps, the most noticeable feature in its progress.

The prognosis appears to be governed by the extent of surface involved; the intensity of the febrile action; the various grades of the process, whether principally vesicles, blebs, or pustules; and the rapidity of the loss of strength.

The treatment has been largely symptomatic, and applied, in most severe cases, to sustaining the patient. Local treatment accomplishes little, if anything, in the

way of checking or modifying the disease. Yet various applications have been employed successfully in affording relief to the pain, burning, and itching which usually prevail, for example, internally strichnine, quinine, iron, arsenic, stimulants, etc., and externally, tar preparations, various soothing salves, baths, zinc and lead lotions and powders, and in my case the greatest relief was afforded by the zinc and lime water lotion suggested by Dr. White. In cases where pus accumulates beneath the crusts absorption should be prevented by promoting the escape of the purulent matter.

CANCER OF THE BODY OF THE UTERUS, INVOLVING THE RECTUM.

BY FRANCIS MINOT, M. D.

Cancer of the uterus limited to the body of the organ, to the exclusion of the cervix, is so unusual that I think a report of the following case will be of interest not only to gynæcologists but to the general practitioner, who is often called upon to treat uterine disease. The diagnosis was obscure while the patient was under my care in the hospital. The gradual failure of flesh and strength, the pain, and the hæmorrhage were suggestive of malignant disease, while the apparently healthy condition of the os and cervix were opposed to that view; and the immediate and continued improvement which followed scraping the surface of the uterine cavity led me to hope that the case was one of so-called hyperplasia of the mucous membrane. The antecedents of the patient were not known to me until after her death, the hospital record stating that the family history was good.

S. C., sixty-one years old, single, a nurse by occupation, entered Massachusetts General Hospital June 28, 1883.[1] Her father died of cancer of the liver, and one uncle also died of cancer. Patient's health good till three years previous, when a bloody vaginal discharge began (she had ceased to menstruate eight years before). The discharge came and went at intervals till October, 1883, after which time it was continuous, quite profuse, inodorous, and contained clots. She noticed occasionally some fullness in the left iliac fossa, with acute pains from time to time; but there was no pain at time of entrance. She had lost some flesh during the preceding winter. The bowels were generally constipated.

She was a large woman, not emaciated. Pulse 108; temperature 99° F. A tumor was obscurely felt in the left iliac region, but its boundaries could not be made out, on account of the thickness of the abdominal walls. There was some tenderness in the same place. The os uteri was small, round, and normal in appearance. There was no hardness, ulceration, abrasion, or granulation about the cervix, os, or vagina. The sound entered easily to the depth of three and a quarter inches upward and backward; it could be freely moved inside the uterus, and was easily felt by the finger in the rectum. The fundus of the womb could be felt behind the pubes on deep pressure, and the organ could be swayed between the hand outside and a finger of the other hand applied to the cervix. No tumor could be detected per vaginam or per rectum. Profuse hæmorrhage occurred during the examination.

[1] See Med. Records, vol. ccclxx., p. 220.

The hæmorrhage continuing, in spite of the administration of ergot and of douches of hot water, the canal of the cervix was dilated with a sea-tangle tent, and on July 10th the interior of the uterus was thoroughly curetted, and a considerable quantity of gelatinous substance was removed. The hæmorrhage gradually diminished, and ceased by the 23d. There was progressive improvement, and the patient left the hospital August 29th, on which day it was recorded that she had "greatly improved, is up all day, and goes out; has no bleeding, and only a slight discharge from the uterus."

For the rest of the history of the case, together with an account of the autopsy, and the specimen, I am indebted to Dr. George R. Fessenden, of Ashfield, the patient's physician, to whose care she returned after she went home. For several weeks her health was comparatively good, there was very little pain, and no hæmorrhage until September 30th, when she had a profuse bleeding and severe pain. The flowing lasted for a few days and was checked by ergot. After this she passed several months quite comfortably, being nearly free from pain, but there was a constant discharge of offensive pus from the uterus. In January the hæmorrhage returned, quite freely, at intervals, with acute pain in the left inguinal region, and she lost flesh and strength rapidly. The bowels became constipated, and during the last five weeks of her life there was no dejection at all; but there were frequent offensive discharges of pus, with fresh coagula, from the vagina. A tumor was felt in the left iliac region. The abdomen was distended with gas, and the peristaltic movements of the intestines were frequent and painful except when controlled by opium. There were paroxysms of severe pain in the left thigh and in the lumbar region. She vomited only two or three times, but there was constant, though slight, nausea. The mind was clear to the last. The temperature never rose above 101.5° F. The pulse averaged 115 in the minute. She died early in April.

Autopsy, twenty-four hours after death. Body greatly emaciated. Abdomen much distended. Large intestine of a dark-red color nearly throughout, and distended with soft, very offensive fæces; at about four inches above the anus it was completely occluded by a hard, red mass, three or four inches in length, which was connected with the uterus. Mesentery, dark red, and studded with cheesy nodules, with a puddle of pus beneath it. A large part of the uterus was destroyed by ulceration and imbedded in pus. The left ovary was of the size of a large filbert, and very hard, grating when cut. The specimen was sent to Professor Fitz, who reported that it was one of sarcoma of the uterus, the extension of the disease through the walls having involved the tissue about the rectum, thus producing the obstruction of the latter. The rectal constriction was so complete that a marked hypertrophy of the muscular coat had taken place.

— Dr. Scott (*St. Louis Courier of Medicine*) relates the case of a native of Missouri who had not been wet all over since 1863. The doctor, being astonished at this fact, made inquiries respecting other residents of the same State. He found that not a third of the people in Missouri bathed once a month, and fifty per cent. do not take a full bath from October to May.

REPORT ON THERAPEUTICS.

FRANCIS H. WILLIAMS, M. D.

ON THE ACTION AND USE OF DIURETICS.

IN the *Practitioner* for April and May one of the editors, Dr. Brunton, discusses this subject in a very interesting and practical manner. The first portion of his paper is devoted largely to a discussion of the physiology of the kidney and the circumstances modifying the secretion of the urine.

It is thought that diuretics may influence the circulation in several ways: by raising the blood pressure generally, or by increasing the local blood pressure in e kidneys, in two ways, (*a*) by contracting the efferent vessels or the arterial twigs which pass directly to the capillary plexus, (*b*) by causing dilatation of the renal arteries, and thus increasing the supply of blood to the kidney. This they may do in more ways than one, for they may either paralyze the vaso-motor nerves of the kidney or act on vaso dilating mechanisms. Diuretics may also act on the secreting cells of the tubules, and may increase the amount of solids excreted by them.

It is known that greater action from diuretics may be obtained by combining them than by using them singly. "Thus we see that digitalis, instead of acting as a diuretic, may completely arrest the renal circulation, and stop the secretion altogether by contracting the blood-vessels. If, however, we can combine it with something which will produce dilatation of the renal vessels, while the general blood pressure remains high, we shall greatly increase the circulation through the kidney, and obtain the desired result. Experiments in regard to this were made by Grutzner with nitrite of sodium. He found that this substance increased the secretion of urine when the blood pressure was reduced to a minimum by curara; and he found that it also had this effect when the blood pressure was raised by imperfect respiration. When the vaso-motor centre was greatly stimulated, however, by allowing the blood to become very venous, the nitrite of sodium no longer produced any increase of secretion.

"All nitrites have an action on the blood-vessels more or less alike. All of them cause the arterioles to dilate, either by an action on their muscular walls or on the peripheral terminations of vaso-motor nerves. One of the commonest diuretics is spiritus ætheris nitrosi, which contains nitrite of ethyl. Sometimes this is combined with acetate of ammonia as a diaphoretic, sometimes with digitalis, broom, or spirit of juniper as a diuretic. We have already seen that the action of the skin and of the kidneys are complementary, so that if we increase the secretion from the one we tend to diminish that of the other. At first sight, then, it might appear curious that we should use the same drug to increase the secretion of both. Yet there can be little doubt, from clinical experience, that nitrous ether is useful for both purposes, and the reason of its utility at once becomes evident when we remember that its action is strictly neither diaphoretic nor diuretic, but simply that of dilating the vessels, and consequently allowing the blood to flow freely in whatever direction it may be determined by other conditions. If by combining it with digitalis we can dilate the renal arteries while those of the other parts of the body remained contracted, it is evident that we shall obtain a much freer flow of urine than we could by the administration of digitalis alone.

"If, instead of a diuretic like digitalis, which acts chiefly through the blood-vessels, we combine spirits of nitrous ether with salts of potassium, which act on the secreting structure, it is evident that we are likely to obtain from the increased circulation in the kidneys caused by the nitrites a much more plentiful secretion than the potassium salts alone would have produced.

"*Uses.* Diuretics may be employed either for the purpose of removing water or solids from the body. They are used, —

"(1.) To remove the excess of fluid met with in the tissues and serous cavities in cases of dropsy.

"(2.) To hasten the removal of injurious waste products and poisonous substances from the blood.

"(3.) To dilute the urine.

"In cases where the accumulation of the fluid depends on venous congestion, as, for example, in cardiac dropsy, those diuretics which act on the general vascular system, like digitalis, strophanthus, squill, or erythrophleum, are most efficient, because they tend to remove the cause of the dropsy, as well as to assist the absorption and excretion of the fluid already effused.

"When the dropsy depends on the disease of the kidneys or liver other diuretics should either be given instead of, or along with, digitalis or squill, even in cases of cardiac disease. Where digitalis or squill are not proving efficacious the addition of a little blue pill greatly assists their action, though it would be hard to say in what way it does so.

"In dropsy depending on kidney disease decoction of broom, and oil of juniper, and nitrous ether are amongst the most reliable diuretics, and copaiba in hepatic dropsy.

"Diuretics are used to increase the secretion of solids in febrile conditions and in cases of kidney disease where the excretion of waste products is deficient, and their retention threatens to prove injurious. In such cases nitrate and bitartrate of potassium, turpentine, and juniper, and caffeine are useful.

"Diuretics are also used to increase the proportion of water in the urine, and thus to prevent the solids being deposited from it and forming calculi in the kidney or bladder, or even to dissolve again concretions which have been already formed.

"Water is, perhaps, the most powerful diuretic which we possess, although fewer experiments have been made with it upon animals than with the others. The diuretic action of water drunk by a healthy man is very marked, and it appears impossible to explain its elimination by a mere increase in blood pressure, whether general or local. It has, as we have remarked, the power of increasing tissue change, and thus multiplying the products of tissue waste which result from it, but it removes those waste products as fast as they are formed, and thus, by giving rise to increased appetite, provides fresh nutriment for the tissues, and thus acts as a true tonic.

"In persons who are accustomed to take too little water the product of tissue waste may be formed faster than they are removed, and thus accumulating may give rise to disease. If water be freely drunk by such persons the product of waste will be removed, and health maintained or restored. Thus many gouty persons are accustomed to take little or no water, except in the form of a small cup of tea or coffee daily, besides what they get in the form of wine or beer. In

such people a large tumbler of water drunk every morning, and especially with the addition of some nitrate or carbonate of potassium, will prevent a gouty paroxysm. Still more numerous, possibly, is the class of people who rise in the morning feeling weak and languid, more tired, indeed, than when they went to bed. Now fatigue may be regarded as the imperfect response of muscles and nerves to stimuli, and such an imperfection in their action may be due either to their imperfect nutrition or to the imperfect removal of the products of their waste. Many such people are well fed, they sleep soundly, and it seems almost impossible to believe that the fatigue which they feel in the morning can result from imperfect nutrition, more especially as one finds that after moving about the languor appears, in a great measure, to pass off. It seems to me that this languor must depend upon imperfect removal of the waste products from the body, as we know that the secretion of urine, in healthy persons, is generally much less during the night than during the day. I am, therefore, in the habit of advising such persons to drink a tumbler of water before going to bed in order to aid the secretion of the urine and of the waste products during the night.

"In some cases, though not in all, the result has been satisfactory, and, possibly, might have been still more so had I added to the water the bicarbonate and nitrate of potassium, which, as I have already mentioned, is so useful in cases of gout.

"Lately a plan of treating gout by draughts of water at intervals during the day has been a good deal employed, and is in many cases successful. As an example of this I subjoin the diet used along with this treatment by a medical friend of mine who has been a martyr to gout, but who feels himself perfectly well as long as he adheres strictly to this course of diet:—

"Half-past seven A. M. Ten fluid ounces very hot water.

"Eight A. M. Breakfast. Equal parts of weak tea and milk, a small quantity of white sugar, a slice of fat bacon without a strip of lean, bread and fresh butter.

"One P. M. Milk pudding, rice, sago, tapioca, macaroni, or blanc mange, and small biscuits with butter; ten fluid ounces hot water.

"Four to five P. M. Ten fluid ounces hot water.

"Six P. M. Dinner. White fish or fowl (usually boiled), greens, bread, no potatoes, claret, seven fluid ounces.

"Eight to nine P. M. Ten fluid ounces hot water.

"Eleven P. M. Ten fluid ounces hot water.

"If he indulges either in meat or game, or drinks copiously of claret, or omits one or two glasses of hot water, he feels gouty and gravelly next day. It is obvious that by this plan of treatment, in which the ingestion of nitrogenous food is most strictly limited, at the same time that every facility is given for the elimination of the products of nitrogenous waste by the large quantities of hot water drunk in the course of the day, the accumulation of waste in the tissues ought to be most effectually prevented.

"*Adjuvants to Diuretics.* As the amount of urine secreted depends upon the difference in pressure between the blood in the glomeruli and the urine in the tubules, it is evident that any pressure on the tubules, whether caused by obstruction of the ureter by a calculus, by the mechanical pressure of dropsical accumulation in abdomen, or by distention of the venous plexus in the kidney itself, will tend to lessen the secretion of urine. Consequently we sometimes find that in such cases diuretics fail to act until the pressure has been relieved by paracentesis in cases of dropsy, or the venous congestion lessened by the use of a brisk purgative or by cupping over the loins.

"If the venous congestion is very great, as in cases of mitral disease or of chronic bronchitis with emphysema and dilated heart, bleeding from the arm may be advantageous or even imperatively necessary. In dilated heart and in mitral incompetence the action of digitalis on the heart itself, strengthening its action, and enabling it more effectually to pump the blood out of the venous into the arterial system, and thus to reduce venous congestion, will aid its action upon the kidneys."

NITRITE OF SODIUM IN ANGINA PECTORIS.

As regards the treatment of angina pectoris, which was spoken of in last year's report, it may be stated that further successful cases have been published in the *Lancet* for November 24, 1883. On the other hand, although Drs. Ringer and Murell consider it a valuable remedy[1] they find that the drug is apt to cause very unpleasant symptoms, and that five or, better, three grain doses should be used.

COCA, TEA, GUARANA, COFFEE.

In the last *Ephemeris*[2] Dr. Squibb gives four valuable and interesting papers on these topics. He has found it very difficult to obtain good specimens of coca, so much so that he has felt obliged to give up making its fluid extract.

Tea, coffee, Paraguay tea, guarana, and Kola nuts have all come into use in widely separated countries, and produce similar effects, namely, to refresh, renew, or sustain the physical and mental organism. And it is curious to find that after they have all been thus long used, although each came from a different natural order of plants, the same active principle, namely, caffeine, could be extracted from all. Coca contains cocaine, a substance which produces similar physiological effects in much smaller doses, although chemically it is very different from caffeine. In order to compare their ability to counteract the tendency to sleep they were tried in the same individual under the same conditions and the result used as a measure of their physiological action.

In this way coca was measured against tea, then coffee against guarana, and finally, to compare the four agents, pure caffeine was taken as a standard.

Having established a certain result with three grains of caffeine, it was found that three fluid drachms of the fluid extract of coca were needed to produce the same result. The three fluid drachms of coca contained .45 grain of cocaine, so that cocaine is about 6.5 times as strong as caffeine. Admitting that it is possible to obtain good coca readily, it would contain much less of cocaine than tea does of caffeine.

FLUID EXTRACT OF CAMELLIA (CHINESE OR JAPANESE TEA).

Tea leaves, as is well known, are prepared and exported with great care, and may easily be obtained of a very uniform quality and strength. After many trials a satisfactory fluid extract of tea was obtained by the process of repercolation, using a menstruum of water, alcohol, and glycerine.

[1] Lancet, November 3, 1883.
[2] Also this JOURNAL, September 18, 1884, p. 283.

Seventy minims of this fluid extract, containing two grains of caffeine, was found to antagonize a tendency to sleepiness as effectively as three grains of pure caffeine, showing that two grains of caffeine in its natural condition is as effective as three grains extracted from the plant and used as caffeine.

Coca, for centuries, was in popular domestic use for the same purposes and effects as tea before it was introduced as a medicine. It would seem best that tea should be introduced to use as a medicine as a substitute for coca, since the one can always be had of uniform good quality while the other cannot. The effects are, probably, identical, and the quantity of tea necessary to produce the effect is much smaller. The cost of coca, measured by its effect, is, perhaps, five times as great as of tea. For these and other reasons it would seem better to use a fluid extract of camellia rather than of coca. Of course a preparation of known and uniform strength would have advantages, for medicinal purposes at least, over the usual cup of tea.

GUARANA.

This substance is a rude, heterogeneous mixture. Neither the ingredients nor their proportions have ever been known with any useful degree of accuracy, and probably the composition is not constant. For various reasons Dr. Squibb has given up making the fluid extract of guarana, and substituted for it a fluid extract of green or unroasted coffee.

FLUID EXTRACT OF GREEN COFFEE.

Like tea, coffee can also be readily obtained of excellent quality and uniform prices.

In the trials of the fluid extract of coffee an amount containing 1.95 grains of caffeine produced the same results as three grains of pure caffeine or two grains of caffeine as it exists in tea, and about 2.58 grains as it exists in guarana.

The method of comparing these agents by a physiological test is not offered by Dr. Squibb as "a method of precision or as worthy of any great trust, and it is especially guarded against being received for more than it is worth. It is only a practical plan, carried out with much pains and care for close guessing at results, but the observations are fairly consistent among themselves, and, therefore, place the agents in a true relation to each other."

This would seem to be too modest a statement of their worth, and the profession are certainly indebted to him for a better acquaintance with the composition and comparative merits of some much-used drugs.

IODOFORM.[1]

Dr. Gaetano Rummo has studied the physiological action of iodoform experimentally in the laboratory of Professor Vulpian, in Paris, and an outline of his paper may interest many practitioners who have and others who will find the antiseptic and local anæsthetic properties of this drug useful.

Iodoform was discovered in 1822, and for about fifteen years it was of interest only to chemists. Bouchardat, in 1836, studied its properties and anticipated its future. In 1853 it was again studied in Paris, and since then, especially during the seventies, in Germany and elsewhere.

All authors admit the local anæsthetic effect of iodoform, and most admit its general anæsthetic action. It has a powerful antiseptic action. Nearly all authors affirm the paralyzing and narcotic action of the drug, and its convulsive action has been seen by many.

It is eliminated principally as iodide. How it acts, in what way it influences the secretions and the gastro-intestinal tract, and many important facts relating to its physiological action, were less well understood. As a consequence surgeons found themselves in the face of a serious accident, iodoform poisoning, and a reaction against this substance was the consequence.

There are three classes of phenomena in iodoform poisoning: —

"(1.) Gastro-intestinal troubles: anorexia, loathing of food, taste of iodoform in the mouth, coated tongue, epigastric pains, vomiting, and sometimes diarrhœa.

"(2.) Cardio-vascular troubles: the pulse is accelerated to 130–140 beats per minute, becomes irregular, and in some cases the pulse wave is weak; the pulse and heart's action denote threatening syncope.

"(3.) Nervous troubles: psychical phenomena appear, periods of excitation, agitations, hallucinations, tendency to suicide, impulsive mania, furious delirium; in some it is possible to find a period of depression characterized by melancholia, particularly sadness with a tendency to weeping, somnolence, loss of memory, comatose state. It is not rare to see convulsions and paralysis.

From this it is not to be inferred that iodoform deserves to be considered a dangerous substance, for in three thousand hospital cases, and in about four thousand out-patients Mosetig-Moorhof did not discover a single case of poisoning.

Iodoform is easily absorbed by the skin deprived of its epidermis; it is absorbed by inhalation, and especially by the stomach and the peritonæum. It is eliminated slowly as iodide of sodium by all the secretory organs, and in small quantities in the breath as iodoform. Large doses cause, in animals, albuminuria and hæmaturia, and fatty degeneration of all organs, especially the liver.

Iodoform does not stop the development of bacteria already begun in putrid liquids, but it is more powerful to prevent their formation.

Hofmokl, who considers iodoform very useful in surgery, suggests that the application of iodoform bougies to long fistulæ of the soft parts is more hurtful than otherwise, as the fistulæ are only stopped up, and the products of decomposition are not discharged. Equally unwise is the filling up of the mouth of a fistula with dry powdered iodoform.

[1] A Year Book of Therapeutics for 1884, edited by Royal W. Amidon.

— Dr. McCallum (*British Medical Journal*, June 14th) reports two cases in boys, in both of whose breasts a milky fluid could be made to exude by pressure upon the nipple. Both boys were masturbators.

— For sprains, Professor Brinton teaches (*Col. and Clin. Record*, July) that the limb is to be put into a vessel of very hot water immediately, boiling water being added as it can be borne, and kept immersed for twenty minutes or until the pain ceases. Then put on a pretty tight bandage, and order rest. Sometimes the joint can be used in twelve hours. If the trouble is more chronic apply a silicate of sodium dressing, and let the patient walk with a cane if the ankle be the joint affected.

Hospital Practice and Clinical Memoranda.

A CASE OF EPILEPTIC MANIA.[1]

BY DAVID G. HALL, M. D.,
Second Assistant Physician Northampton Lunatic Hospital.

So much has been written on the subject of epilepsy, it may seem to be a rather worn-out subject. There are occasionally cases, however, whose symptoms differ from the ordinary epileptic fit where the patient cries out and suddenly falls, has spasmodic contractions of the muscles, froths at the mouth, etc., and within a short time recovers consciousness. Fits of this kind are, of course, common everywhere in private practice, but cases of epilepsy where the fits are accompanied by periods of great excitement are rarely met with except in hospitals for the insane, partly from the fact that they are less numerous than the milder variety, and chiefly because such patients are placed in institutions before the disease has assumed its most violent form. Such cases are by far the most dangerous of all classes of insane patients. When not excited they are a constant source of annoyance to their fellow-patients; they are always complaining of something; never satisfied with their food, no matter what it is, although at the same time they will eat twice as much as their digestive organs should be required to assimilate. They have almost always bad dispositions, which, of course, is not surprising when we consider the strain the nervous system undergoes during the periods of excitement. I use the term excitement, for in some cases this seems to be a more prominent symptom than the fits themselves.

One of the worst cases of epileptic mania which has been in the Northampton Hospital for several years was admitted May 15, 1882.

A man, forty-two years of age, about five feet six inches tall, thick set and muscular; weight on admission 143 pounds, at present weighing 190, showing a gain of forty-seven pounds. He has for years been subject to sexual excess, and also to the use of intoxicating liquors. The following are the facts upon which the physicians who signed the certificate of commitment based their opinions, to wit: "Attacks of acute mania, during which he commits the most violent acts, and is unsafe and difficult of restraint. On Sunday, May 14th, in a semi-nude state, he left his bed, and, with a large club, struck his own sister on the head several times, producing severe scalp wounds and injury to the brain. A tendency to destroy property. Further, we think these attacks are the sequel of epilepsy, to which he has been for a long time subject."

While investigating the case more carefully we learned the patient had been employed as clerk in a stock broker's office in New York, but on account of ill health had been obliged to give up work, and for a few months had been living with his father and mother, who reside in a neighboring town.

During an excitement he got out of bed and jumped through a window into the yard, carrying the sash and all before him. Here he found his sister and another woman with two little children. Picking up a cart stake, about three feet long and two inches in thickness, he started for the children, but the women seized them, and ran into a corner of the yard, where they were followed by this epileptic, who had now reached a state of uncontrollable excitement. He struck his sister with the club twice on the top of the head, and once on the back of the neck, when his father interfered, and prevented his doing further injury. Blood oozed from the sister's ears, she vomited at intervals, and was unconscious most of the time for several days, but after a long illness she recovered sufficiently to attend to her household duties, although it is said her nervous system still shows some effects of the shock it received.

Little could be learned as to hereditary tendency to disease of the nervous system, for all the relatives who ever came to see the patient seemed disinclined to talk about the case, and were especially reticent in regard to any nervous diseases which have occurred in the family. After a great deal of roundabout questioning the following fragments of family history were obtained: All members of the family are of a very nervous and excitable temperament. An uncle of the patient was an epileptic, and a child of the sister assaulted has epileptic convulsions. The patient himself had convulsions during teething, but these are said to have been very slight, and to have lasted only a short time. The first excitements of which I could get any history commenced about twenty years ago, soon after he left the army. At that time they were not very severe, and occurred at much longer intervals than at present. He married about this time a handsome and accomplished woman, and three children have been born to them, none of whom have been epileptic. Every year the excitements increased in severity until he would attack any one with whom he came in contact, no matter whether it was friend or foe.

When admitted to the hospital, the day after the assault, he was very nervous, had a rapid pulse, was restless and noisy for a few days, and then, apparently, recovered. In a few weeks, however, the excitement returned in all its fury, and has ever since occurred at intervals varying from a few days to three months. As a rule it comes on gradually, and in this respect differs from the majority of the cases of epileptic mania. He begins to find fault with everything and everybody, considers himself wholly recovered, and thinks he is greatly abused because he is not allowed to go home; sometimes, when sitting quietly, he will lose consciousness for a few moments, the eyes become fixed, and a slight spasm or twitching of the muscles will occur, especially those of the legs and fore-arms; the walk is slow and unsteady; the legs seem to be stiff and unwieldy; in a day or two he becomes more and more nervous and excitable, and finally loses all control of himself. He will, at times, jump up and down in his room, swing his arms about, and shout at the top of his voice. The face is sometimes pale, but usually flushed. The eyes become so congested they closely resemble a case of acute conjunctivitis, and they have a peculiar, wild stare, which is anything but pleasant to look at. But perhaps the most striking thing one observes is the change in the voice. It is only with the greatest effort he is able to make himself understood. It takes him a long time to get started, and then there is an explosion of words, which are chopped off abruptly, so to speak, as though the muscles concerned in articulation became spasmodically contracted. This high state of excitement does not, however, con-

[1] Read before the Hampshire District Medical Society, September 11, 1884.

tinue for any great length of time. There are always intervals throughout the day when he can take a little nourishment. As a rule the periods of excitement continue from five to ten days, but occasionally they last two or three weeks, when they gradually disappear, leaving him weak and irritable.

Thus we have a case which so evidently belongs under the head epilepsy or, more properly, epileptic mania, there can be no doubt that must be the proper diagnosis. Yet, as far as we know, the patient was never known to fall, never bit his tongue but once, and his lips once, never had the "epileptic cry" or anything approaching the "aura," which so often occurs in this disease.

In regard to the prognosis, all we can say is that this case, like all other cases of true epilepsy, is hopeless. If he lives many years he will, probably, become more or less demented.

The treatment at first consisted chiefly of tonics, but as the patient gained so rapidly in flesh, and showed himself capable of eating, at least, twice as much as two ordinary men, they were soon discontinued. When the excitements are coming on he is given large doses of "salts and senna," and also moderate doses of bromide, which latter are continued until he has wholly recovered.

In regard to responsibility, almost any number of pages might be written. In the eyes of the law this patient would not, of course, be held responsible for a moment, and no physician would dare give as his opinion that this man should be held accountable for his misconduct; yet insane persons, if their minds are not too far gone, are oftentimes just as liable to take advantage of their condition as any of the other descendants of Adam. Within a month a patient told me "if old so and so (speaking of another patient) did n't keep away from him he would split his head open with his chamber." When reproved for it he said, "If I should do it nobody could hurt me. They say I am insane, and the law would n't punish an insane person." And so it is with the present case. I cannot but believe this patient at times takes advantage of his condition, and does things he ought not to do when his mind is sufficiently clear for him to know better. Several months ago he had an attendant whom he very much disliked. He resented everything he asked him to do, and never hesitated to quarrel with him if the least opportunity presented itself. So during an excitement he struck the attendant with an earthen chamber, which had been very carelessly left in the room, making an ugly gash just above the left eye.

Several days after he had recovered he told me very quietly he intended to kill his attendant, and would do it yet; thus not only showing he remembered the affair, but acknowledging he did it intentionally. So, if we were to judge only from the patient's own words, we should be obliged to say he was, at least to a certain extent, responsible; but if we stop to follow the case all through, compare the actions of the patient now with his conduct before the disease became developed, remember how the loss of self-control became more and more marked as the excitements increased in severity, we are compelled to acknowledge that this patient should be considered irresponsible, and should in no way be made to answer for what, in all probability, he never would have done had he not become subject to this disease.

Medical and Surgical Journal.

THURSDAY, OCTOBER 2, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY, No. 4 PARK STREET, BOSTON, MASS.

MR. TAIT'S ADDRESS.

AT the annual meeting of the Canada Medical Association, recently held in Montreal, Mr. Lawson Tait delivered a noteworthy address on Abdominal Surgery. The words of such a master will be widely read, but, we believe, with a certain disappointment that the distinguished author should not have manifested in himself "the power of judging the question solely upon its merits, and entirely apart from any prejudice, tradition, or personal bias." Indeed it seems to us that Mr. Tait was actuated quite as much by a desire to castigate Sir Spencer Wells as to lay before the profession the results of his own experience and observation. The animus of the address is well shown by the author's words in his allusion to Mr. Keith, to whom, in Mr. Tait's opinion, "is due the whole credit of the modern development of abdominal surgery," namely, "it has ever seemed specially hard that while wealth and a title have been the lot of the man who had done nothing but obstruct progress, yet to the author of our present proud position nothing has come save a good deal of misrepresentation and abuse."

But passing over the personalities of this truly polemic discourse, we read with interest Mr. Tait's explanation of his remarkable success; it is briefly this: entire restriction to his chosen field, the most minute attention to every detail, and great personal attention to cleanliness in every part of his work. In common with Keith, Bantock, Savage, and many others, Mr. Tait has given up the spray and all the details of Listerism, believing, after long and careful trial, that they prejudice his success. In ovariotomy he believes in the intra-peritoneal treatment of the pedicle, and has discarded the clamp. As regards the use of perchloride of iron for tanning the stump after hysterectomy, which he says is "the only contribution Sir Spencer Wells has ever made to abdominal surgery," he believes that owing to the impossibility of accurately closing the abdominal wound where a clamp is necessarily used on a thick pedicle, the iron is liable to trickle down into the peritoneal cavity and cause fatal peritonitis. In the treatment of uterine myomata Mr. Tait believes with Mr. Thornton, Professor Hegar and others, that in the great majority of cases removal of the uterine appendages arrests menstruation, arrests also the growth of the tumor, and in many cases causes it to entirely disappear. There is, however, in his opinion, a soft, œdematous variety of myoma on which removal of the appendages exercises

no control, and in such cases and in those in which for any reason the appendages cannot be removed he advises supra-vaginal hysterectomy, for which operation he predicts a brilliant future.

Mr. Tait's success in the surgical treatment of chronic ovaritis and of chronic inflammation and occlusion of the tubes is well known. He points out the frequent difficulty of diagnosticating these cases, especially when the ovaries and tubes are prolapsed and adherent. We believe, with Mr. Tait, that in doubtful cases an experienced surgeon is fully justified in making an exploratory abdominal incision. Of Battey's operation Mr. Tait has not come to a decided opinion, and indeed his experience has been purposely limited to only six cases, as he has not cared to prejudice the results of his other work by complicating it with what seemed to him a doubtful proceeding. He believes the future of the operation is still open for discussion and thinks it may prove beneficial and therefore justifiable chiefly in cases of menstrual epilepsy.

We had supposed it to be generally acknowledged that McDowell was the first to plan and execute the operation of ovariotomy; but Mr. Tait says that the first operation "was performed unwittingly, in 1701, in a Scotch village by Robert Houston," and that eighty-six years afterwards Houston's example was "imitated" by McDowell. We do not believe that the profession is yet prepared to take from McDowell his proud distinction and bestow it upon one who at best performed but an accidental and incomplete operation.

THE DRY DIET CURE OF DYSPEPSIA.

For fully half a century the medical profession has been acquainted with the advantages of a diet exclusively of milk in certain gastro-intestinal affections. It has been found that for irritable and inflammatory states of the digestive tube this regimen often furnishes the most favorable conditions for sustentation and restoration. Clinicians have given precise indications for its employ. Thus Gubler, in his Commentary on the Codex, very judiciously remarks that "milk agrees better with the irritable and congested stomachs of gouty and herpetic subjects, and those that have made excessive use of condiments and alcoholic stimulants, than with those who have been suffering from atonic dyspepsia, or who have tendencies to catarrhal or serous diarrhœa."[1] "There are," he continues, "certain gastralgias and dyspepsias which are not benefited by milk diet."

At a recent meeting of the Société de Therapeutique, Paris, Dr. Henri Huchard gave an account of his experience in the treatment of several inveterate cases of dyspepsia, attended with dilatation of the stomach; after complete failure of the milk regimen he changed his course, prescribing a dry diet and abstinence, as far as possible, from liquids. The result was most gratifying, all his patients getting well. What was characteristic of these cases was the aggravation of the gastric troubles on the ingestion of liquids. In all there was marked distention of the stomach, amounting in some instances to chronic dilatation; there were besides, gaseous eructations, colicky pains with sometimes cardiac oppression, a furred condition of the tongue, with often nausea and vomiting, but that which especially attracted attention was the supervention of attacks of suffocation or pain on the attempt being made to swallow any kind of liquid food. One of Huchard's patients — fortunately cured by abstinence from liquids — used to have prolonged fainting fits on taking a few spoonfuls of porridge. "Milk, broth, gruel caused such extreme discomfort that the young woman preferred to go without food. For the constipation from which she was suffering — and it is noteworthy that patients afflicted with this form of dyspepsia are generally constipated — I ordered one day a glass of Hunyadi János, but the first mouthful caused such anguish of suffocation that she could take no more." Huchard, from whose article in the *Bulletin general de Therapeutique* (August 30th) we quote, gives to Chomel the honor of having first noted and clearly defined this "dyspepsia of liquids," although older authorities have remarked in cases of feeble digestion that the ingestion with meals of considerable quantities of liquids determines distention of the stomach and diminution in the secretion of gastric juice, while it is a saying of Beau that "good stomachs belong to those who drink little, and who drink nothing at meal time." Chomel described a peculiar swashing sound (*bruit de clapotment*) heard in the stomach, and generated by the presence in the cavity of that viscus of an excess of liquids and of gas, as being pathognomonic of this affection. This *swashing* noise is heard when the patient is suddenly turned from one side to the other, or when he otherwise changes his position; a good way, and one which Chomel recommends, is to place the patient before you in a standing posture, and with both your hands on the sides of his abdomen to give several abrupt lateral impulsions.

Having observed that in this form of dyspepsia the stomach digests solids much better than liquids, Chomel formulated the dry diet treatment, which consists in the utmost possible abstinence from liquids; the patient not being allowed to take more than one small cup of his ordinary drink during his repast. Full baths of lukewarm water and lavements were permitted in ordinary to maintain the requisite fluidity of the blood. An interval of at least eight hours between the morning and the afternoon meal was enjoined; if the time of breakfast was fixed at eleven A. M., the dinner could not be had till seven P. M. Soups of any kind might be taken, provided they were made quite thick. To these soups were added bread in small quantity, roast, boiled, or broiled meats warm or cold, fish, eggs, legumes, on condition that sauces should be used with them very sparingly. Fruits were permitted with moderation except such as are very juicy, *e. g.*, melons, grapes, peaches, etc. With this form of dyspepsia such foods as are finely divided and pulverulent (the powder of meat for instance) agree very well; raw oysters on bread, or scalloped

[1] Gubler, Commentaries du Codex, p. 203 (cited by Huchard).

oysters are unobjectionable dishes. For the constipation which afflicts these patients those purgatives should be selected which present themselves in a solid form.

Huchard cites instances in the practice of his eminent master, where under the influence of this regimen all uncomfortable dyspeptic and reflex symptoms disappeared, and in which health was afterwards enjoyed except at such times as the person through indiscretion transgressed by indulgence in some favorite beverage; even trifling indiscretions being sometimes followed by oppression, colicky pains, palpitations, *glou-glou* sounds sufficiently loud to attract the attention of standers by, etc. One of these patients could not take a glass of cold water of an evening without suffering the next morning from dryness of the mouth, flatulent distention of the stomach, and suppression of urine.

According to Huchard, then, abstinence from liquids, or the "dry diet cure," to which Fonssagrives has given the name of *xerophagia* (Gr. "I eat dry food"), produces excellent effects in certain dilatations of the stomach, in atonic dyspepsias, in the dyspepsia of liquids. He thinks also that this kind of regimen is applicable to other affections characterized especially by excess of arterial tension — to atheromatous patients, to individuals affected with interstitial nephritis, aortic affections, certain cases of angina pectoris, with considerable elevation of vascular pressure, and to persons predisposed to divers hæmorrhages, cerebral congestions, etc.

"GUIDE, PHILOSOPHER, AND FRIEND."

THE leading London medical weeklies have all printed, as usual, their "students'" numbers, containing information which, doubtless, is of use to young men about to study in the great capital. We cannot help thinking, however, how appalled many a young disciple of Galen must be at the amount and solidity of the good advice which is tendered him. One hundred pages of reading-matter and advertisements is the contribution of *one* of these journals to the special needs and temptations of the medical student, and at least two other weekly periodicals are equally generous. We note with interest one innovation, modeled, as we are told, on Mr. Hamerton's Intellectual Life. It consists of letters of advice, drawn up to meet various imaginary conditions. The following supposed communications are printed at length: "From the Dean of a London Medical School to a Widow who proposes that her Son shall enter the Medical Profession." "To the Same, from a Country Apothecary." "From a London Physician to an old School-Fellow, who has asked Advice about his Son." "From a Successful Surgeon to a Young Genius who has decided to study Medicine." "From a Country Practitioner to his Son, who has just entered at a London Hospital." "From a Prosperous Young Specialist to his Brother, who desires to Follow in his Footsteps." "From a Second-Year's Student to his Friend, a Freshman."

This department still falls short of that fullness which one looks for in a complete letter-writer, inasmuch as there must be a number of young men who do not find their own special circumstances fully detailed, and may, therefore, not know exactly what to do. It would be well to make some additions, as, for instance, "From a Distinguished Professor of Dermatology to a Young Man afflicted with Freckles;" "From a Wealthy Maiden Aunt to her Nephew, with Enclosure to buy a Skeleton;" "From a Renowned Obstetrician to his Second Cousin, recently married." Other appropriate topics for this department will, doubtless, suggest themselves to our esteemed contemporary before the issue of its next "student's number."

MEDICAL NOTES.

— *Science*, taking a comparative view of the characters of the English and American associations for the advancement of science, both held this year on this side the Atlantic, says, among other interesting observations, that in the matter of paying compliments and moving thanks in an easy and graceful manner, our English cousins have the advantage of us. It is the almost universal custom for the chairman of the Section to thank the reader of a paper, and often in elaborate terms. This consumes a good deal of time, and it is a question whether such wholesale compliment is desirable. It was observed, however, that the distinguished and genial presiding officer of one of the Sections made use of two quite different formulæ for expressing his appreciation of the merits of the paper: in one case hoping "that the Section would join him in thanking Professor —— for his interesting and important communication upon this subject;" and in another, "that the Section would join him in thanking Professor —— for his communication upon this interesting and important subject." The importance of the proper arrangement of words was never shown to better advantage.

— The *Medical News* (September 13th) discourses pleasantly of one of the latest born of the family of the cocci — the *Influenzacoccus;* "Dr. Otto Seifert had the opportunity of observing an epidemic of influenza in Würzburg. It was not exactly a pandemic. The first case came under his notice, in the Julius Hospital, on the 4th of January, 1883, and the last on the 24th of March in the same year; and they numbered, in all, *seven*. He was, therefore, enabled to cope single-handed with the whole epidemic. He not only routed it, horse and foot, but he also took it captive, and has studied its appearance and habits with the care and interest due to so distinguished a prisoner of war. As the reader anticipates, it is a coccus, and a micrococcus at that. Enlarged 350 times, its length is from 1.5 μ to 2 μ, and its breadth 1 μ; and its number in the sputum is legion. It arranges itself mostly in long chains, the rank and file, less often in pairs (diplococci), and occasionally it stands forth alone (monococcus). It was caught in the secretions of the nares and in the sputum in the earlier actions of the campaign. Later, when these became fouled and purulent, the coccus forsook them. In the tears, even when they most bedimmed the eyes, it was not found.

The captive was clad by its conqueror in a robe of methyl-violet, and made a magnificent appearance. In order to establish its identity, laborious comparisons of the nature of control experiments were made. Examinations of the same secretions of many other sick than the seven were conducted, but with a negative result. The coccus was not there; nor was it found in any blood — even of the seven. The inoculation of two white guinea-pigs failed. Like other fierce captives it grew sullen and refused to do its trick. Or was it like those noble beasts which become sterile in captivity? Dr. Otto Seifert magnanimously gave it a new robe, of almost Tyrian purple, but the spirit of the victor prevailed, and he has called it by a name not its own — 'Influenzacoccus,' and has broken its spirit by likening it to the base coccus of gonorrhœa."

— Osteotomy for genu valgum was discussed at the International Medical Congress, and Macewen's supracondyloid osteotomy was acknowledged by all to be the most satisfactory one. Professor Ogston gracefully acknowledged that his own operation (fracture of the internal condyle) did not yield as good results as Macewen's simpler and safer operation. Professor Schede said that, with German surgeons, he had accepted Macewen's operation as the best. He differed from Dr. Macewen in doing his operation in one respect — he did not use but one chisel, and considered the withdrawal of the instrument from the wound a serious matter, in that it led to an unnecessary disturbance of the parts, and frequently some difficulty occurred in reintroducing the chisel. He thought that in many cases the tibia, rather than the femur, was involved, and in these cases he preferred his own operation (section of the tibia). Mr. Bryant complimented the gentlemen on the manner in which they had given up their pet operations, and had accorded to the supracondyloid operation (Macewen's) its just value.

— In a paper read before the Buffalo Medical Society by Dr. Pryor it is stated that two thirds of the births in that city are reported for registration by midwives. He criticised sharply the ignorance of many of these women, whose fees for a labor case were only $3 to $5. In the discussion upon this paper one speaker said that he knew a midwife of Buffalo who said she "had attended one thousand successive successful cases, among which she had turned fifty times in cross presentations, has had fifty footling cases, and one of placenta prævia, had three times called a doctor to apply the forceps, and had removed the placenta with her hand fifty times." A more striking commentary than these figures on the competence of the midwife would be hard to find. One case in twenty of transverse presentations and the same ratio of footling cases! Yet after putting her hand into the uterus of every twentieth woman for the placenta, besides performing version fifty times, the midwife sends three times for a doctor to put on forceps!

— A nursery-maid, in London, aged seventeen, has been charged with willful murder and convicted of manslaughter for killing a child by tying a scarf round its neck to stop its crying while she was wheeling it before her in a perambulator. She was reading a book, and, naturally, any noise like that of a crying child diverted her attention from the more important occupation in hand. The diversions of most nurses hereabouts are not literary, but we wonder what some mothers would say if they ever became aware (as probably they never do) of the neglect to which their children are exposed while mademoiselle, in the French cap, is chattering with her companions or flirting with her *garçon*.

— Lawson Tait says: Any woman who has an ovarian tumor removed in her own house is a fool for her pains.

Correspondence.

THE CHOLERA EPIDEMIC OF 1873.

A REVIEW OF A CONGRESSIONAL REPORT.

Lowell, *September* 22, 1884.

Mr. Editor, — Perhaps there is no better work on this dreaded disease, as it has appeared in our own country, than this Congressional Report. Covering over a thousand pages, all phases of the subject have received most careful attention. The epidemic of 1873 extended over eighteen States, but happily did not visit Massachusetts. The Report was published in 1875, and embodies the experience of a large number of physicians. It was prepared under the direction of the Surgeon-general of the army. Full records were collected of 7356 cases, and of these more than half (fifty-two per cent.) died. The results in the use of the more common drugs are thus stated: —

In the treatment by calomel, in large and small doses, there was a mortality of twenty-three per cent.; calomel and opium there was a mortality of thirty-one per cent.; calomel, opium, and acetate of lead, the mortality was forty per cent.; calomel, opium, and stimulants the mortality was fifty per cent. In cases where stimulants alone were employed the mortality was increased to fifty-nine per cent. Where the preparations of iron were used, the mortality was thirty-three per cent., while from the acid treatment but eight per cent. is recorded. Of the latter the cases reported are scarcely numerous enough to afford reliable data — sixty-four cases with five deaths."

"The evidence is conclusive that the exhibition of opium followed by alterative doses of calomel, and absolute rest in the recumbent posture, almost invariably arrested the disease when in the premonitory stage. In the advanced stages the entire range of the Pharmacopœia seems to have been brought into use with no better results than have been obtained in previous epidemics."

The Report "strongly corroborates the beneficial results obtained from the use of sulphate of iron and dilute sulphuric acid as prophylactics during an epidemic."

As so much has been said lately about the valuable work of Dr. Koch and his colleagues, it is interesting to recall what has been done in the same field by previous observers. In 1872 a most interesting series of experiments was made by Nedswetzky, of Russia, on the bacteria of cholera dejections. A summary of his results is given in this Congressional Report.

When the bacteria were subjected to *quinine, camphor, carbolic acid, tar, calomel,* or *chloral* they lived and moved as before. In the experiment with *opium* he added one drachm of the tincture to two drachms of the rice-water discharges. The bacteria all remained alive until the sixth day, when a few of them died. The same result occurred with *nux vomica. Chloroform* and *muriatic acid* were almost immediately fatal; while death of the bacteria invariably followed the addition of *sulphate of iron, chlorine* water, *tannic, nitric,* or *sulphuric acids* to the rice-water discharges.

If it be true, as is now very generally believed, that these living bacteria, or "bacilli," cause the disease, the importance of the above experiments cannot be overestimated.

The conclusions with regard to the general character of Asiatic cholera are summarized in the following seven "propositions" under the head of ætiology: —

"Proposition I. That Asiatic cholera is an infectious disease resulting from an organic poison, which, gaining entrance into the alimentary canal, acts primarily upon and destroys the intestinal epithelium.

"Proposition II. That the active agents in the distribution of the cholera poison are the dejections of persons suffering from the disease in any of its stages. That in these dejections there exists an organic matter which, at a certain stage of decomposition, is capable of reproducing the disease in the human organism to which it has gained access.

"Proposition III. That cholera dejecta coming in contact with and drying upon any objects, such as articles of clothing, bedding, and furniture, will retain indefinitely their power of infection. That in this manner a sure transmissibility of the cholera infection is effected, and that a distinct outbreak of the disease may occur by such means at great distances from the seat of original infection.

"Proposition IV. That the specific poison which produces the disease known as cholera originates alone in India, and that by virtue of its transmissibility through the persons of infected individuals or in the meshes of infected fabrics the disease is carried into all quarters of the world. That cholera has never yet appeared in the western hemisphere until after its route of pestilential march has been commenced in the eastern world, and that its epidemic appearance upon the North American continent has invariably been preceded by the arrival of vessels infected with cholera sick, or laden with emigrants and their property from infected districts."

The epidemic of 1873 in the United States is believed to have been traced to a fair held in the Punjab in 1867.

"Proposition V. That the respiratory and digestive organs are the avenues through which individual infection is accomplished; that through the atmosphere of infected localities cholera is frequently communicated to individuals; that water may become contaminated with the specific poison of cholera from the atmosphere, from surface washings, from neglected sewers, cess-pools, or privies, and that the use of water so infected will induce an outbreak of the disease.

"Proposition VI. That the virulence of a cholera demonstration, the contagion having been introduced into a community, is influenced by the hygienic condition of the population, and not by any geological formation upon which they reside.

"Proposition VII. That one attack of cholera imparts to the individual no immunity from the disease in the future, but that the contrary seems to be established."

Very truly yours,

WM. H. LATHROP, M. D.

ELECTION OF HONORARY MEMBERS OF THE MASSACHUSETTS MEDICAL SOCIETY.

MR. EDITOR, — Have the Councilors of the Massachusetts Medical Society any authority to *elect* honorary members of said Society? In trying to settle this question I would beg the liberty to call the attention of the Fellows of said Society to some of the provisions of the Charter and subsequent acts of the Legislature.

By the Charter, Art. I., Section 5, it was enacted that the Fellows of said Society may *elect* such persons as they shall deem proper to be Fellows thereof; but the number of said Society who are inhabitants of this Commonwealth shall not at any time be more than seventy.

The Act of 1803, Section 1, authorized the *Fellows, for the time being,* of the Massachusetts Medical Society, in any meeting called and holden for the purpose before the next annual meeting, to *elect* into that Corporation, and to be Fellows thereof, such and so many suitable persons, being physicians or surgeons, resident within this Commonwealth, as they may see fit.

Section 2 authorizes the Fellows at the next annual meeting and afterward at every annual meeting thereof to choose so many Councilors as said Society from time to time judge necessary. And Section 3 says: "And the said Councilors, at any stated meeting of the same, and only those meetings, and after three months' nomination of every candidate, and not otherwise, by a major vote of those present may *elect* any suitable person or persons to be a Fellow or Fellows of said Society, provided that all practicing physicians and surgeons resident within this Commonwealth, who shall be so elected, shall, within one year after such election, subscribe the By-Laws of said Society, or otherwise declare in writing their assent to the same, or such election shall be void. And all persons not practicing physicians or surgeons, or not resident within this Commonwealth, who shall be so elected shall be deemed honorary members of the said Society."

The above are all the provisions of law by which Fellows or the Councilors of the Massachusetts Medical Society were ever authorized to *elect* Fellows or members of said Society. Certain acts have been passed at different times by which licentiates and others might become members, but no provisions by which any person could be *elected* a member of said Society.

The law of 1859 declares that "No person shall hereafter become a member of the Massachusetts Medical Society except upon examination by the Censors of said Society.

This act certainly deprives not only the Councilors but the Fellows also of said Society of all power to *elect* any person to membership of the Society, and consequently all persons *elected* to be members of said Society since that time were illegally elected.

It is true there may be a doubt whether the law of 1859 was binding upon the Society before the vote of the Society, October 4, 1876, directing and authorizing the secretary to record the acceptance of the Society to said act of the Legislature (the Legislature,

in the Charter, not having reserved any right to alter, amend, or annul said Charter without consent of said Corporation). Yet the vote of the Society at that time is in such form as clearly to imply that the Society did accept the act at the time of its passage.

I leave it for the Fellows of the Society to judge whether the statement made at the last annual meeting that "all the honorary members of the Society *elected* since March, 1859, were illegally elected" was a remarkable one. M.

September 20, 1884.

Miscellany.

HOW TO PREPARE ANTISEPTIC DRESSINGS OF MERCURIC BICHLORIDE.

Now that the advantages of the mercuric bichloride as an antiseptic dressing have been clearly established, receiving as it does the sanction of so many eminent surgical authorities, and becoming extensively employed in hospital and private practice, writes Dr. Charles Meigs Wilson, in the *Philadelphia Medical Times* (September 6, 1884), a few words as to its proper preparation for such purposes may be of interest. Corrosive sublimate is soluble in water in the proportion of thirty grains to the ounce. Various vehicles have been employed, as glycerine, ether, alcohol, or the latter in equal parts and water. Of all these the preference should be given to water as a medium, because of its capability of imbibition and solution, and the readiness with which it may be obtained. Sufficient sodium chloride should be added to solutions of the sublimate (an equal part) to prevent the latter's decomposition and the formation of calomel. In hospitals it is possible to have the solutions freshly prepared and frequently renewed, but in private practice this is not always feasible, especially if the case be of long duration, and at a distance from a drug shop. A convenient solution for private use, and one which will keep indefinitely, is the following: —

Hydrarg. bichlor.	℥ ii.
Sodii chlorid.	℥ i.
Aquæ distillat.	f ℥ iv. M.

One fluid drachm of this added to a pint of water makes a solution of about one to a thousand. Sir Joseph Lister makes use of the following formula in preparing solutions of corrosive sublimate: One drachm by weight of a solution, one part of corrosive sublimate in one and one half parts of glycerine, contains two fifths its weight, or twenty-four grains, of the sublimate. This multiplied by one thousand (the proportion of water required) gives twenty-four thousand grains, or nearly three pints. It is, however, much more convenient to use fluid measure than weight, and one fluid drachm of the glycerine solution referred to requires four pints of water to produce the one to one thousand solution. Surgical authorities are pretty well agreed that one to one thousand is the proper solution to use for douching, washing, and dressing wounds. For vaginal or uterine irrigation, one to two thousand is the proper strength, and no stronger solution should be used in abdominal surgery. The best medium in which to use the corrosive sublimate for surgical dressings is finely-pulverized wood. This may be obtained at a number of the instrument makers' and drug shops. The wood-wool is sterilized by being subjected to a dry heat (above 220° F.). It is then soaked for twelve hours in a one half per cent. solution of corrosive sublimate. Afterwards it is spread out and dried. It is then placed in a bag of gauze (such as is used for the Lister dressing) or mosquito-bar netting, prepared by being saturated with the following solution: —

Corrosive sublimate.	gr. x.
Alcohol	f ℥ ix. et f ℥ ii.
Glycerine	f ℥ i. et ℥ xx.

This dressing is applied dry. Care should be taken to apply the dressing so that the margins of the bag extend an inch or so beyond the margins of the wound. This dressing is capable of absorbing twelve times its weight of water. It is applied with the ordinary roller, and requires no mackintosh or covering.

In St. Mary's Hospital, Brooklyn, we are told that a very useful combination is obtained as follows: Dissolve six grains of corrosive sublimate in ether and alcohol, of each one half ounce. Dissolve sodii chlor., twenty-four grains, in glycerine, one ounce. Mix the two solutions, and triturate thoroughly with one pound of wood-wool. Spread to dry, and after the ether and alcohol have evaporated mix well with one part to ten, by weight, of powdered naphthaline. Two powerful germicides are thus combined.

MISSED ABORTION; SCLEROSIS OF THE PLACENTA.

AT a recent meeting of the Obstetrical Society of New York a paper was read by Dr. H. J. Garrigues narrating the case of a woman, aged thirty, married ten years, in her sixth pregnancy, who presented herself for treatment, having had daily slight hæmorrhage for four weeks. The size of the womb corresponded to the fourth month. No sounds being audible, pregnancy, with death of the fœtus, was diagnosticated. About a week later the bleeding had ceased, and the patient felt well.

About nine months after her last menstruation a fœtus and placenta, in one mass, were expelled with moderate pain. They were perfectly fresh. The fœtus, a female, seemed to be at the end of the fourth month, with partial arrest of development. The mouth was large, the lips only partially formed; hare-lip and cleft palate existed. The epidermis had come off to a great extent, forming casts of the hands and feet. The soft parts appeared much atrophied.

The placenta measured eight by six centimetres, and appeared mainly hard, whitish, and lardaceous, without cotyledons. Its fœtal surface was normal. The cord, twenty centimetres in length, had a velamentous insertion. Of the membranes only some pieces of gelatinous tissue remained, and of the decidua only a few long shreds were found. The death of the fœtus was due to the sclerosis of the placenta, which is supposed to be of syphilitic origin.

A dead fœtus undergoes either putrefaction or mummification. In the former case it causes fever, and if not expelled must be removed. In the latter case, as in that under consideration, it may be retained for many months. The wasting of the soft parts should be attributed not so much to absorption of the liquids as to starvation, inasmuch as scarcely any placental tissue was left. A similar condition is found in adults deprived of food. Missed abortion is of some practical interest. Where the fœtus is decomposed its removal is indicated, but no treatment is called for in case of

mummification. As the diagnosis will generally be doubtful, inasmuch as the uterus might contain a living fœtus, it is advisable to abstain from active measures. The possibility of this condition occurring should be borne in mind so as to avert unjust suspicion, for example, when a married woman, in the absence of her husband, expels a fœtus corresponding to a development of shorter duration than the father's absence. The woman may require treatment for uterine disease, or, perhaps, both she and her husband for syphilis.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 13, 1884.

Deaths reported 3066 (no reports from Brooklyn, Buffalo, and Milwaukee): under five years of age, 1388; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 887, diarrhœal diseases 606, consumption 372, lung diseases 110, typhoid fever 109, diphtheria and croup 91, malarial fevers 53, whooping-cough 44, scarlet fever 29, cerebro-spinal meningitis 27, puerperal fever eight, erysipelas four, small-pox one. From *malarial fevers*, New Orleans 19, New York 11, Baltimore nine, St. Louis seven, Chicago, Cincinnati, and Nashville two each, Charleston one. From *whooping-cough*, New York 23, Philadelphia five, Chicago and Baltimore three each, Boston and District of Columbia two each, St. Louis, Providence, and Nashville one each. From *scarlet fever*, New York 10, Chicago and Cincinnati three, Boston, District of Columbia, Pittsburg, and Holyoke two each, St. Louis, Providence, Springfield, Somerville, and Braintree one each. From *cerebro-spinal meningitis*, New York six, Philadelphia five, Nashville and Woburn three each, Cambridge two, Chicago, Baltimore, New Haven, Lawrence, Holyoke, Upton, and Peabody one each. From *measles*, New York 13, Chicago two. From *puerperal fever*, Philadelphia, Boston, and St. Louis two each, Chicago and Cincinnati one each. From *erysipelas*, New York two, Cincinnati and District of Columbia one each. From *small-pox*, New Orleans one.

Cases reported in Boston: typhoid fever 48, scarlatina 45, diphtheria nine, and measles one.

In 110 cities and towns of Massachusetts, with an estimated population of 1,416,011 (estimated population of the State 1,955,104), the total death-rate for the week was 22.9 against 22.10 and 19.75 for the two previous weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending August 30th, the death-rate was 25.3. Deaths reported 4245: infants under one year 1695: acute diseases of the respiratory organs (London) 181, diarrhœal diseases 967, scarlet fever 70, whooping-cough 69, measles 64, fever 52, diphtheria 23, small-pox (London 12, Liverpool, Sheffield, and Sunderland one each) 15. The death-rates ranged from 19.5 in Birkenhead to 37.8 in Preston; Birmingham 32.3; Blackburn 35.4; Bradford 26.6; Leeds 29.8; Leicester 29.5; Liverpool 32.6; London 20; Manchester 34.1; Nottingham 29; Sheffield 28; Sunderland 28.4. In Edinburgh 16.5; Glasgow 25; Dublin 29.9.

For the week ending August 30th, in the Swiss cities there were 59 deaths from diarrhœal diseases, consumption 22, lung diseases 12, diphtheria and croup two, typhoid fever two, small-pox one, measles one. The death-rates were, at Geneva 9.2; Zurich 17; Basle 24; Berne 21.1.

The meteorological record for the week ending September 13th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

Deaths reported 2850 (no reports from New Orleans and Buffalo): under five years of age, 1324; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 798, consumption 342, lung diseases 142, diarrhœal diseases 453, diphtheria and croup 130, typhoid fever 90, malarial fevers 34, whooping-cough 32, scarlet fever 29, measles eight, cerebro-spinal meningitis eight, erysipelas five, puerperal fever six, yellow fever two. From *whooping-cough*, New York 16, Philadelphia four, Brooklyn three, Chicago and Milwaukee two each, Baltimore, Cincinnati, New Haven, Cambridge, and Haverhill one each. From *malarial fevers*, St. Louis 12, Brooklyn eight, New York and Baltimore five each, Chicago, Cincinnati, Nashville, Charleston, and Newburyport one each. From *scarlet fever*, Chicago seven, District of Columbia six, New York and Philadelphia five each, Baltimore and Providence one each. From *measles*,

New York six, Chicago two. From *cerebro-spinal meningitis*, New York and Philadelphia two each, Chicago, Cincinnati, Worcester, and Lawrence one each. From *erysipelas* Chicago two, St. Louis, Milwaukee, and New Haven one each. From *puerperal fever*, Chicago and Milwaukee two each, Boston, Cincinnati, and Newburyport one each. From *yellow fever*, Brooklyn two, Boston one.

Cases reported in Boston: scarlet fever 44, typhoid fever 34, diphtheria 19, and measles three.

In 109 cities and towns of Massachusetts, with an estimated population of 1,345,140 (estimated population of the State 1,955,104), the total death-rate for the week was 20.64 against 22.09 and 22.10 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending September 6th, the death-rate was 24.1. Deaths reported 4053: infants under one year of age 1471; deaths in London 1529: acute diseases of the respiratory organs (London) 167, diarrhœal diseases 848, whooping-cough 77, scarlet fever 63, fever 55, measles 48, diphtheria 43, small-pox (London 11, Liverpool two) 13. The death-rates ranged from 13.1 in Derby to 38.8 in Bolton; Birmingham 28.7; Blackburn 36.8; Bradford 24.9; Leeds 27.6; Leicester 30.6; Liverpool 31.6; London 19.9; Manchester 30.2; Nottingham 30.8; Sheffield 26.4. In Ediaburgh 15.2; Glasgow 23.9; Dublin 29.3.

For the week ending September 3d, in Paris, there were 175 deaths from consumption, typhoid fever 32, diphtheria and croup 27, measles 18, whooping-cough seven, erysipelas five, scarlet fever three. The death-rate was 21.64.

For the week ending September 6th, in the Swiss towns, there were 34 deaths from diarrhœal diseases, consumption 22, lung diseases nine, typhoid fever eight, diphtheria and croup five, scarlet fever two, erysipelas one, small-pox one. The death-rates were, at Geneva 16.3; Zurich 19.7; Basle 14.7; Berne 22.2.

The meteorological record for the week ending September 20th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date. Sept., 1884.	Barometer. Daily Mean.	Thermometer. Daily Mean.	Thermometer. Maximum.	Thermometer. Minimum.	Relative Humidity. 7.23 A. M.	Relative Humidity. 3.23 P. M.	Relative Humidity. 11.23 P. OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM SEPTEMBER 20, 1884, TO SEPTEMBER 26, 1884.

MIDDLETON, PASSMORE, major and surgeon. Having reported from sick leave of absence, assigned to duty at Fort Leavenworth, Kansas. Paragraph 2, S. O. 188, headquarters Division of Missouri, September 19, 1884.

WHITE, ROBERT H., captain and assistant surgeon. Ordered for duty as post surgeon, Fort Gaston, Cal. Paragraph 2, S. O. 110, headquarters Division of California, September 13, 1884.

WILSON, WILLIAM J., captain and assistant surgeon. From Department of Dakota to Department of the East.

GARDINER, J. de B. W., captain and assistant surgeon. From Department of Arizona to Department of the East.

CORBUSIER, WILLIAM H., captain and assistant surgeon. From Department of the East to Department of Arizona.

LA GARDE, L. A., captain and assistant surgeon. From Department of Missouri to Department of Dakota. Paragraph 1, S. O. 220, A. G. O., September 19, 1884.

LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR TWO WEEKS ENDING SEPTEMBER 27, 1884.

HARMON, G. E. H., passed assistant surgeon. September 16th, from Navy Yard, Norfolk, to Naval Academy.

MCCLURG, W. A., passed assistant surgeon. September 16th, from Naval Academy to Naval Hospital, Philadelphia, Pa.

LEACH, PHILIP, passed assistant surgeon. September 16th, from Hospital, Chelsea, Mass., to the Palos.

COLES, J. W., surgeon. September 16th, as member and recorder of Naval Examining Board, and to Hospital, Philadelphia.

DERR, E. Z., passed assistant surgeon. September 16th, to Navy Yard, New York.

MACKIE, B. S., surgeon. September 16th, from Training Ship Jamestown as member and recorder of Naval Examining Board.

KINDLEBERGER, D., medical inspector. September 18th, from the Hartford, sick.

DICKSON, S. H., passed assistant surgeon. September 19th, permission to leave United States.

BLOODGOOD, D., medical inspector. October 1, 1884, to Washington for examination preliminary to promotion, and as to qualifications for sea duty.

HORD, W. T., medical director. October 1, 1884, as member of Naval Examining Board.

TURNER, T. J., medical director. October 1, 1884, as member of Naval Examining Board.

BOYD, J. C., passed assistant surgeon. September 25, 1884. Placed on waiting orders.

OBERLY, A. S., surgeon. October 1, 1884, to Washington for examination preliminary to promotion, and as to qualifications for sea duty.

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held on the second Thursday of October, at four o'clock, P. M. It will be the quarterly meeting, and lunch will be provided.

HENRY M. FIELD, M. D., *Secretary.*

DIED, — September 26, 1884, Luther Clark, M. D., M. M. S. S., of Boston, aged seventy-four years.

BOOKS AND PAMPHLETS RECEIVED. — A Treatise on Physiology and Hygiene for Educational Institutions and General Readers. Fully Illustrated. By Joseph C. Hutchison, M. D., LL. D. New York: Clark & Maynard. 1884.

Original Articles.

THE ABSORPTION OF SUGAR AND ALBUMINOIDS BY THE STOMACH.[1]

BY ROBERT MEADE SMITH, M. D.,
Professor of Comparative Physiology in the University of Pennsylvania.

As the conviction gradually gained ground that absorption in the small intestine could not be attributed to mere filtration and osmosis, and as in default of other plausible explanation the conveyance of foodstuffs into the tissues of the mucous membrane of the alimentary canal was held to be a special function of the protoplasm of the epithelial cells, the question as to how the wall of the stomach absorbed gained in importance; and if the epithelial cells are the main organs of absorption. All the points of contrast which may exist in the manner and rapidity of absorption in the stomach and small intestine will be of great importance in explaining the peculiarities of these organs. For since there is no occasion for doubting the identity of the protoplasmic contents of cylindrical epithelial cells of different localities, the differences in the power of absorption possessed by different cells may be referred to the dissimilarity in structure of the free border of those cells; and as is well known the intestinal and gastric epithelial cells possess these differences in the most marked degree. Indeed this dissimilarity of structure may be sufficient to explain the absorption of fat by the former and its non-absorption by the latter, without acknowledging the necessity for the previous reduction of the fat to the form of an emulsion.

On the other hand, for many hours daily the free surface of the epithelial coat of the stomach is bathed in a fluid whose degree of acidity in other circumstances is sufficient to destroy protoplasmic vitality. And while the escape of the stomach from self-digestion may be explained as due to the neutralization of this acid by the alkali of the blood and lymph, while the above might apply on anatomical grounds to the sub-epithelial tissues, it could scarcely hold for the free protoplasmic surfaces of the epithelial cells. Consequently, if the protoplasm of the gastric epithelial cells preserves its vitality in spite of the fact that it is separated from an acid digestive fluid only by a thin porous cap of mucus, it must either be held that these special cells, in contradistinction to other protoplasmic bodies, escape the action of the gastric acid, or that the acid of the gastric juice so condenses the mucus in the free surfaces of the cells as to prevent further entrance of fluid. In the latter case we could then only expect that the walls of the stomach would be capable of absorption when the acidity of the gastric contents had fallen below a certain degree.

Without regarding the numerous old observations which seemed to prove the absorption of various drugs and poisons by the walls of the stomach, Tappeiner[2] and Von Auret[3] have studied the absorption of sugar and peptone by the stomach by a method which is free from all the objections which might be urged against the earlier investigations. Both of these investigators, the former especially, found that the walls of the stomach were but slightly capable of absorption, and both failed to explain the conditions under which this limited absorption occurred.

From a few experiments made by Prof. C. Ludwig it seemed possible that the stomach of the frog might yield clearer results. Since the stomach of the frog is clothed with an epithelium which in its essential features is identical with that of the mammalian stomach, at his suggestion I commenced a series of studies, part of which were made last summer in Leipzig, and the remainder in the autumn in Philadelphia, on the following plan: The stomach was exposed in frogs which had fasted for at least a week, the pylorus ligated, and the abdominal wound carefully sewed up. After then introducing into the stomach either through the mouth or œsophagus a weighed amount of food of known composition, the frogs were kept for varying lengths of time and then killed by pithing. The stomachs were then excised and their contents collected, tested as to reaction, and weighed in the wet and dry state, and then incinerated; when grape sugar had been introduced the dried residue of the gastric contents was dissolved in a measured quantity of water and the percentage of sugar remaining in the stomach determined by titration with Fehling's fluid. Often instead of in a single frog the pylorus was tied at the same time in a number of frogs, each of which then received the same amount of food, and all were then killed and the contents of their stomachs examined together. By this means individual deviations from the general rule were eliminated as much as possible, and greater certainty in the results assured. And since of the hundred and more frogs subjected to this operation no more died than in an equal number kept in confinement without undergoing any operation it may be concluded that the operation itself does not interfere with the normal activity of the stomach.

Although the stomachs of fasting frogs with the exception of a slight amount of mucus were nearly always found empty, it does not necessarily follow that such would be the case after ligation of the pylorus, since the operative procedures might cause an irritative secretion to be poured out into the stomach; the following experiments were made to settle this point: —

A number of fasting frogs, after ligating the pylorus, were kept alive from one to six days and the contents of their stomachs then examined. With a single exception a small amount of acid mucoid fluid was found which was carefully removed, weighed, and its weight again determined after drying and incineration.

The following tables give the mean figures obtained in numerous experiments: —

After Twenty-four Hours' Ligation of Pylorus.

	Mgr.	In percentage.
Total contents of stomach	504	100.00
Water	496	98.40
Organic matter	7.5	1.49
Ash	0.4	0.07

After Forty-eight Hours' Ligation of Pylorus.

	Mgr.	In percentage.
Total contents of stomach	407	100.00
Water	395	97.00
Organic matter	11	2.83
Ash	0.5	0.11

After Seventy-two Hours' Ligation of Pylorus.

	Mgr.	In percentage.
Total contents of stomach	395	100.00
Water	383	96.97
Organic matter	11.4	2.88
Ash	0.5	0.12

[1] Communication from the Leipzig Physiological Institute.
[2] Zeitschrift für Biologie, xvi.
[3] Archiv f. Anat. u. Phys., 1881.

After Ninety-six Hours' Ligation of Pylorus.

	Mgr.	In percentage.
Total contents of stomach	552	100.00
Water	538	97.46
Organic matter	13	2.35
Ash	1.5	0.27

As a mean of the above determinations it may be stated that after ligation of the pylorus the stomach of the frog contains a fluid which contains 2.35 per cent. of organic matter.

After One Hundred and Twenty Hours' Ligation of Pylorus.

	Mgr.	In percentage.
Total contents of stomach	1040	100.00
Water	1011	96.99
Organic matter	23	2.22
Ash	6	0.58

After One Hundred and Forty-four Hours' Ligation of Pylorus.

	Mgr.	In percentage.
Total contents of stomach	311	100.00
Water	304	97.75
Organic matter	7	2.22
Ash	0.3	0.10

In another case in which the pylorus has been ligated for 144 hours the stomach was completely empty.

The preceding figures show that the percentage of water in the contents of the stomachs of which the pylorus has been ligated for from one to six days is subject to but slight variation, running from 97 to 98.5 per cent. The total contents of the stomach is also nearly a constant quantity, averaging from 300 to 500 milligrammes, in only one case reaching one gramme, and in another case falling to the condition generally found in the stomachs of fasting frogs with open pylorus.

The fact that neither the total amount nor the percentage of water in the contents of the stomach is subject to variation, at any rate not proportionately to the time during which the pylorus remains ligated, deserves especial attention in order to determine whether the secreting activity of the empty stomach ceases shortly after the ligation of the pylorus, and the secreted fluid then remains unabsorbed, or whether the secretion and absorption go on in equal degrees. Without attempting to solve this question, it is sufficient for the purposes of the present research to know that ligation of the pylorus, even when maintained for six days, does not produce any disturbance of function or abnormal secretion which could interfere with or complicate the results of the experiments as to the degree of absorption in the stomach.

THE ABSORPTION OF GRAPE SUGAR.

In three different series of experiments the sugar was introduced into the stomach either dry or in 28.5 or 16.8 per cent. solution. In order to avoid loss and to insure greater purity in the results, when dry sugar was given the pylorus was first ligated, and then a small incision made in the œsophagus, through which the stomach was first dried with absorbent cotton and the sugar then introduced through the same opening. The œsophagus was then ligated at its entrance into the stomach so as to prevent loss through vomiting or by passage into the intestine. The following results were obtained: —

1. *Three Hours after Introduction of Sugar.*

Dry Sugar.			Sugar in 28.5 Per Cent. Solution.			Sugar in 16.8 Per Cent. Solution.		
Sugar.		Water.	Sugar.		Water.	Sugar.		Water.
Given.	Absorbed.		Given.	Absorbed.		Given.	Absorbed.	
173 mgr.	103 mgr.	775 mgr.	200 mgr.	75 mgr.	801 mgr.	182 mgr.	65 mgr.	1275 mgr.

2. *Six Hours after Introduction of Sugar.*

Dry Sugar.			Sugar in 28.5 Per Cent. Solution.			Sugar in 16.8 Per Cent. Solution.		
Sugar.		Water.	Sugar.		Water.	Sugar.		Water.
Given.	Absorbed.		Given.	Absorbed.		Given.	Absorbed.	
200 mgr.	161 mgr.	1049 mgr.	200 mgr.	150 mgr.	1923 mgr.	182 mgr.	71 mgr.	1477 mgr.

3. *Nineteen Hours after Introduction of Sugar.*

Dry Sugar.			Sugar in 28.5 Per Cent. Solution.			Sugar in 16.8 Per Cent. Solution.		
Sugar.		Water.	Sugar.		Water.	Sugar.		Water.
Given.	Absorbed.		Given.	Absorbed.		Given.	Absorbed.	
200 mgr.	175 mgr.	3775 mgr.	400 mgr.	175 mgr.	2088 mgr.	182 mgr.	170 mgr.	1587 mgr.

4. *Twenty-two Hours after Introduction of Dry Sugar.*

Sugar Given.	Sugar Absorbed.	Water.
200 mgr.	150 mgr.	4089 mgr.

5. *Twenty-four Hours after Introduction of Sugar.*

	Dry Sugar.			Sugar in 16.8 Per Cent. Solution.		
	Sugar Given.	Sugar Absorbed.	Water.	Sugar Given.	Sugar Absorbed.	Water.
a.	200 mgr.	186 mgr.	2589 mgr.	182 mgr.	82 mgr.	3351 mgr.
b.	200 mgr.	184 mgr.	516 mgr.	–	–	–

6. *Forty-eight Hours after the Introduction of Sugar.* Sugar entirely disappeared from stomach; this was also the case after *seventy-two hours.* In each instance from 1000 to 2000 milligrammes of water were found in the stomach.

In each one of the above experiments sugar had been absorbed by the stomach, but with different degrees of rapidity, depending on the density of the solution of sugar employed. The following table shows this point more clearly: —

Time after the Introduction of Sugar in Hours.	Dry Sugar.		Sugar in 28.5 Per Cent. Solution.		Sugar in 16.8 Per Cent. Solution.	
	Per Cent. Absorbed of the Amount given.	Per Cent. of Sugar remaining in the Fluid in Stomach.	Per Cent. Absorbed of the Amount given.	Per Cent. of Sugar remaining in the Fluid in Stomach.	Per Cent. Absorbed of the Amount given.	Per Cent. of Sugar remaining in the Fluid in Stomach.
3	60	9.03	38	15.60	30	9.18
6	80	3.72	75	2.60	39	7.51
20	87	0.66	87	1.20	90	0.76
24	92	0.86	97	0.12	44	2.98

From the above it is evident, in the first place, that in equal periods the amount of sugar absorbed increases with the density of the preparation of sugar introduced into the stomach, and consequently the rapidity of absorption sinks in proportion to the amount of fluid poured out into the stomach, facts which would be expected, whatever be the mechanism of absorption. And, in the second place, it is clear that the stomach from which absorption has taken place contains more fluid than was introduced with the sugar.

Amount and Composition of the Fluid poured out by the Stomach.

1. DRY SUGAR.

	Water Poured Out. Mgr.	Residue free from Sugar. Per Cent.	Sugar Absorbed. Mgr.	Relation between Water Poured Out and Absorbed. Sugar = 1.
After 3 hours.	775	2.32	103	0.13
After 6 hours.	1049	2.86	161	0.04
After 19 hours.	3775	2.67	175	–
After 22 hours.	4089	3.04	150	–
After 24 hours.	2589	2.24	186	–
After 24 hours.	516	3.10	184	–

2. SUGAR IN 28.5 PER CENT. SOLUTION.

	Water Poured Out. Mgr.	Residue free from Sugar. Per Cent.	Sugar Absorbed. Mgr.	Relation between Water Poured Out and Absorbed. Sugar = 1.
After 3 hours.	301	3.65	75	0.25
After 6 hours.	1423	2.60	150	0.10
After 20 hours.	1888	2.08	175	0.11

3. SUGAR IN 16.8 PER CENT. SOLUTION.

	Water Poured Out. Mgr.	Residue free from Sugar. Per Cent.	Sugar Absorbed. Mgr.	Relation between Water Poured Out and Sugar Absorbed.
After 3 hours.	375	2.93	65	0.17
After 6 hours.	577	?	71	–
After 18 hours.	687	3.35	170	–
After 24 hours.	2451	?	82	–

To obtain any conception as to the amount and character of this fluid the amount of water introduced with the sugar must be deducted from that found in the stomach at the end of the experiment, and the amount of sugar present in the dried residue must be subtracted from the total amount of the latter.

It is seen from the above tabular statement that the amount of fluid in the stomach increases with the duration of absorption, and with the amount of sugar disappearing from the stomach; and that the amount of fluid actually poured out by the stomach is inversely proportional to the amount of water introduced with the sugar; thus it reaches its greatest amount when dry sugar is given, and is least when the sugar is given in the form of a weak solution. And it further appears that the amount of water by weight poured out by the stomach is always largely in excess of the amount of sugar absorbed.

These results are evidently of an osmotic character, but in searching for the osmotic equivalent it must be remembered that the fluid poured out is not pure water, but a solution of various substances, as shown in the above table in the column which gives the percentage of residue which was free from sugar, and which, since not introduced with the food, must have been contributed by the stomach. Further, the amounts of this residue closely coincide in each case, and, what is well worthy of attention, are almost identical with the amounts of solid residue which were found in stomachs of the frogs in whom the pylorus had been tied and no food given. It might, therefore, be concluded that the gastric glands had been stimulated by the presence of sugar in the stomach. If this be correct then it must also be assumed that two separate and independent processes were going on at the same time in the stomach, a secretion by the glands and an absorption of sugar by the epithelial cells, an assumption which is rendered hardly tenable when it is remembered the reaction of the contents of the stomach after the administration of sugar was never acid, but nearly always markedly alkaline.

Therefore the presence of a solid residue free from sugar can evidently not be regarded as opposed to the absorption of sugar by osmosis, especially when it is remembered that the sugar when absorbed does not

enter pure water, but blood or lymph, whose constituents must also be concerned in the osmotic process.

In concluding this portion of my subject it must be stated that even after the sugar has entirely disappeared from the stomach, forty-eight or seventy-two hours after its introduction, the stomach then contains far more fluid than is found in a stomach whose pylorus has been tied and no food given. Thus after forty-eight hours 1967 milligrammes of fluid with 3.4 per cent. solids were found, and after seventy-two hours 2440 milligrammes with 3.3 per cent. solid.

ABSORPTION OF ALBUMEN.

For experiments as to the absorption of albuminoids, fresh frog's muscle seemed the most suitable food, since, when taken from a fasting animal, it contains but little fat, and is almost constant in the percentage of water which it contains. From several estimations I obtained 78.24 per cent. of water, and 20.83 per cent. of organic matter, figures which very closely correspond with the results of the analyses of Von Bibra, and as all the frogs were kept under similar circumstance these figures, therefore, serve as the data on which my calculations are based.

Before proceeding with the experiments on frogs with ligated pylorus I first gave to each of a large number of normal frogs 200 milligrammes of frog's muscle, and then killed them after the lapse of forty-eight hours. In each case the stomach was found empty, from which it was concluded that the amount given was readily digested.

But when the same amount was given to frogs in whom the pylorus had been previously ligated it was found that a much longer time was required before the food was absorbed; only after ninety-six hours was solution completed. When large amounts of frog muscle, such as 500 or 1000 milligrammes, were given, the time of digestion was still further prolonged, sometimes not being complete after 120 hours.

According to the observations of E. Brücke with artificial gastric juice, this delay in the process of digestion in the ligated stomach may be attributed to the accumulation of digestive products, since the amount of fluid poured out by the stomach increased with the increase of time during which the food remained in the stomach, and the reaction of the contents of the stomach up to the time of complete solution of the food was always strongly acid. The delay could not, therefore, have been due to diminished acidity of the gastric juice.

Since the time required for the solution of a given amount of frog's muscle varied in different animals, the duration of the experiment cannot be used as a means of measuring the progress of digestion. The experiments can only be grouped by comparing the characters of the gastric contents.

With a single exception the stomach in all cases contained more water than was contained in the food, while the organic matters were sometimes in excess, and sometimes less than was contained in the amount of frog's muscle given as food. That a diminution in the amount of organic matter found in the stomach after feeding can only be due to absorption is self-evident, but it does not by any means follow that this difference in weight represents the amount absorbed. On the other hand, the cases in which the organic residue found in the stomach was in excess of that given with the food do not necessarily indicate an interruption in the process of absorption, for the stomach not only contains the amount of food administered, but with the entrance of food the stomach commences to fill itself with gastric juice, as shown by the solution of the food, the acid reaction, and the excess of water. From the experiments made on the secretion poured out into the empty stomach after ligation of the pylorus, and in those in which sugar was given, it can be concluded that, in all probability, in the stomach in which digestion of meat is taking place a secretion, containing from 2.5 to 3.0 per cent. organic residue, will also be poured out. Under the assumption of this percentage, and of the origin of the excess of water in the secretion of gastric juice, it is possible to follow much more closely the steps of the experiments.

In the following series of experiments those are first detailed in which there could be no doubt but that a part of the albuminoids of the food were absorbed, since the contents of the stomach at the end of the experiment were poorer in organic matter than the food. The experiments are arranged according to the degree of difference between the organic constituents of the food and of the contents of the stomach: —

I.

	Duration of Digestion. Hours.	Loss of		In Contents of Stomach.		Degree of Digestion
		Organic Matter. Mgr.	Water. Mgr.	Organic Matter. Mgr.	Water. Mgr.	
1	120	35	135	27	907	Complete.
2	24	104	396	89	758	Incomplete.
3	72	104	396	87	1493	Incomplete.
4	96	104	396	81	1315	Complete.
5	144	42	158	13	576	Complete.
6	96	42	158	12	574	Complete.
7	162	41	156	10	294	Complete.
8	96	42	158	6	514	Complete.
9	48	42	158	6	628	Complete.
10	96	42	158	4	139	Complete.
11	48	208	792	145	1093	Incomplete.
12	24	208	792	142	1149	Incomplete.
13	96	208	792	81	1328	Incomplete.

Since the difference in weight between the amounts of organic matter in the food and in the contents of the stomach after digestion is liable to cause an erroneous estimate of the actual amount of matter which has been absorbed by the stomach, an attempt has been made in the following table to correct these figures. The order of arrangement of the experiments is the same as in the preceding table: in the second column is noted the excess of organic matter in the food given over that found at the end of the experiment in the contents of the stomach, while the third column gives the excess of water in the stomach over that contained in the food. The fourth column is calculated on the supposition that the water of the gastric contents has been secreted as gastric juice and contains 2.5 per cent. of organic matters. If the figures of the fourth column of this table are added to those of the third column of Table I. the sum will represent the amount of organic matters which the stomach must have contained had no absorption taken place; but if the actual amount of organic matter found in the stomach is subtracted from this sum the amount absorbed will be determined; this quantity is represented in the following table in the column headed "Probably absorbed": —

II.

	In the Stomach.		Excess of Water regarded as Secretion, with 2.5 Per Cent. Organic Matter. Mgr.	Amount probably Absorbed. Mgr.
	Less Organic Matter than in Food. Mgr.	More Water than in Food. Mgr.		
1	8	762	19	17
2	15	654	16	31
3	17	1389	34	51
4	23	1019	25	48
5	29	418	10	39
6	30	216	5	35
7	31	138	3	34
8	36	356	8	44
9	36	370	9	45
10	38	19 mgr. less.	3	41
11	63	811	20	83
12	66	457	11	77
13	127	636	13	140

As already stated, in the cases where 500 milligrammes and more of frog's muscles were given as food the stomach still contained undissolved food; nevertheless absorption of the portion of food which had passed into solution had occurred, for less organic matter was found in the stomachs than had been given in the food. Thus there was a loss of organic matter in —

Exp.
2. Of 15 mgr. after 24 hours after feeding with 500 mgr. muscle.
3. Of 17 mgr. after 72 hours after feeding with 500 mgr. muscle.
11. Of 63 mgr. after 48 hours after feeding with 1000 mgr. muscle.
12. Of 66 mgr. after 124 hours after feeding with 1000 mgr. muscle.
13. Of 127 mgr. after 96 hours after feeding with 1000 mgr. muscle.

These differences are too great to fall within the limit of error in weighing. And, moreover, it must be remembered that the amount of organic matter found in the stomach is not derived solely from the food but also from the secretion poured out by the gastric glands, so that the amount absorbed must have been in reality greater than the above figures which give the loss of organic matter. Since the strongly acid reaction of the contents of the stomach points to a continuation of the act of digestion, it follows from the above observations that digestion and absorption can occur simultaneously; or, more strictly, that the power possessed by the gastric epithelium of absorbing digested albumen is not prevented by the contact of a strongly acid secretion.

Since, therefore, absorption commences before solution of the food is complete, it may be expected that simultaneously with or shortly after the completion of digestion the constituents of the food will be absorbed.

If now the experiments in Table I. are examined in which digestion was complete, namely, Nos. 1, 4, 5, 6, 7, 8, and 9, the following differences are found between the amounts of organic matter in the stomach and in the food. In —

1. 8 mgr. after 120 hours after feeding with 137 mgr. muscle, with 35 mgr. organic residue.
4. 23 mgr. after 96 hours after feeding with 500 mgr. muscle, with 104 mgr. organic residue.
5. 29 mgr. after 144 hours after feeding with 200 mgr. muscle, with 42 mgr. organic residue.
6. 30 mgr. after 96 hours after feeding with 200 mgr. muscle, with 42 mgr. organic residue.
7. 31 mgr. after 162 hours after feeding with 195 mgr. muscle, with 41 mgr. organic residue.
8. 36 mgr. after 96 hours after feeding with 200 mgr. muscle, with 42 mgr. organic residue.
9. 36 mgr. after 48 hours after feeding with 200 mgr. muscle, with 42 mgr. organic residue.
10. 38 mgr. after 96 hours after feeding with 200 mgr. muscle, with 42 mgr. organic residue.

If it is supposed that the organic matter found in the stomach is derived solely from the digested food it must then be concluded that in Nos. 8, 9, and 10 of the above series the digested albumen was almost entirely absorbed. But if, on the other hand, it is admitted that an important portion of the chyme is derived from gastric secretion, and my argument is accepted, that the water which is secreted by the stomach brings with it 2.5 per cent. of organic matter, then Nos. 1, 5, 6, and 7 of the above series are also to be included in the group in which the digested albumen was almost entirely absorbed (see Table II.).

Passing now to the consideration of the experiments in which the stomach after death contained not only more water, but also more organic matter, than was given with the food, we find again a confirmation of the statement that the passage of water from the walls of the stomach to its interior carries with it a considerable quantity of organic matter.

The following table brings out these points: —

	Duration of Digestion. Hours.	Loss of		In the Stomach.		Degree of Digestion.
		Organic Matters. Mgr.	Water. Mgr.	Organic Matters. Mgr.	Water. Mgr.	
a.	48	42	158	43	821	Incomplete.
b.	48	42	158	57	955	Incomplete.
c.	120	43	154	46	1567	Incomplete.
d.	90	52	200	58	786	Incomplete.
e.	72	57	219	60	1196	Incomplete.
f.	48	60	228	66	851	Incomplete.
g.	48	104	396	119	1463	Incomplete.
A.	124	42	158	51	1412	Complete.
B.	77.5	36	139	52	1196	Complete.
C.	143	28	106	51	1146	Complete,
D.	192	25	104	52	1903	Faintly acid. Complete, Neutral.

Since after the administration of food a fluid containing organic matter passes into the cavity of the stomach, it is clear that from the mere quantitative comparison of the food and the contents of the stomach no conclusion can be at once drawn as to the degree of absorption which has taken place. But if, as in the consideration of the absorption of organic matter, the calculation is made under the assumption that the excess of water in the stomach over that given with the food has also brought into the stomach 2.5 per cent. of organic matter in solution, it is clear that even when more organic matter is found in the stomach than was contained in the food absorption has nevertheless taken place. This is shown in the following corrected table:

	In the Stomach.		Excess of Water regarded as Secretion, with 2.5 Per Cent. Organic Matter. Mgr.	Probable Amount Absorbed of Organic Food Stuffs. Mgr.
	More Organic Matter than in Food. Mgr.	More Water than in Food. Mgr.		
a.	1	663	17	16
b.	15	797	20	5
c.	3	1513	38	30
d.	6	568	14	8
e.	3	777	19	16
f.	6	625	16	10
g.	15	1077	27	12
A.	9	1256	31	22
B.	8	957	24	8
C.	3	1040	26	3
D.	27	1826	46	17

Although the small amounts absorbed in *A*, *B*, *C*, and *D*, in spite of the total solution of the food, form an apparent contradiction to the earlier experiments

the discrepancy can be readily explained. For it was noted in the experiments in which the sugar was completely absorbed that the stomach did not then empty itself, but even after the lapse of a long interval contained a fluid with 3.3 to 3.4 per cent. organic residue, and it is perfectly warrantable to assume that a similar state of affairs holds in the case of the digestion and absorption of albuminous food; and that being the case, the organic matters found in the stomach in the latter instance may be referred to the fluid secreted by the stomach. Accepting these data as a basis for calculation, it is found that the contents of the stomach in A contains 3.62, in B, 4.34, in C, 4.45, and in D, 2.73 per cent. of organic residue, figures which so closely correspond to the percentage of organic matters in the stomach after it is known that all the food has been absorbed that they cannot be used as an argument against the total absorption of the albuminoid elements of the food.

As to whether the above theories are actually true, or as to what forces are concerned in the absorption of albumen by the mucous membrane of the stomach, no demonstration can be given until chemistry permits a better quantitative separation of the constituents of the gastric juice and the derivatives of digested albuminous food.

At present the assumption that the absorption in the stomach is of the nature of a process of diffusion seems the most probable. Several facts harmonize with this view. In the first place the slowness of absorption; for if it were of an osmotic nature absorption would only be possible when the albumen had been converted into peptone or into some substance not already present in the blood or lymph. Again the fact that the stomach fills itself with fluid in exchange for the absorbed albumen is a further indication of the osmotic character of the process. And finally, the anatomical structure of the gastric epithelium furnishes another point in favor of this view, for the surface exposed to the cavity of the stomach is composed of porous mucus incapable of spontaneous protoplasmic movement.

Apart from all hypothesis, however, the experiments detailed above clearly show the marked difference between absorption in the stomach and in the intestine. For after the completion of digestion the intestine rapidly absorbs both the digested food products and the greater part of the glandular secretions, so that only a comparatively dry residue remains unabsorbed, while in the stomach after the absorption of sugar or albumen there remains a considerable volume of fluid for several hours. It may of course be objected that the state of affairs which exists in a stomach with ligated pylorus does not necessarily hold in that organ when in its normal condition, but the above experiments show that the ligation in the frog is but slightly disturbing, and the most that can be claimed is that in the normal condition the fluids transuded in absorption pass into the intestine to again from there enter the blood.

APPENDIX.

DETAILS OF EXPERIMENTS.

Analysis of Frog's Muscle.

Water	78.2366
Matters soluble in alcohol	1.0323
Matters insoluble in alcohol	19.7823
Ash	0.9486
	99.9998
Water = 78.2366	80.43
Solids = 21.7633	19.57
99.9999 (Rms.)	100 00 (Von Bibra.)

Absorption of Albuminoids.

EXP. I. May 7, 1883. Frog: weight 55.8 grm. Pylorus ligated; 0.2855 grm. frog's muscle introduced into stomach. Contents of stomach after 48 hours = 0.9204 grm. Reaction acid; muscle not completely digested.

Water	0.8505
Insoluble in alcohol	0.0549
Soluble in alcohol	0.0115
Ash	0.0035
	0.9204

EXP. II. May 7, 1883. Frog: weight 48.25 grm. Pylorus ligated at 5.30 P. M.; 0.2755 grm, frog's muscle introduced into stomach. After 72 hours contents of stomach = 1.0575 grm.

Water	0.9955
Soluble in alcohol	0.0160
Insoluble in alcohol	0.0438
Ash	0.0022
	1.0575

EXP. III. May 8, 1883. Frog: weight 55 grm. Pylorus ligated, and 0.253 grm. frog's muscle given. After 90 hours contents of stomach = 0.7860.

Water		0.7236
Insoluble in alcohol	Albumen	0.0470

Ash	0.01
	0.50 grm.

Absorption of Sugar.

EXP. XXXV. December 11, 1883. 0.25 grm. of crystalline grape sugar (97 per cent. pure) was dissolved in 26 cc. distilled water and mixed with the mucus from the stomach of three frogs, and dried in a crucible in hot-water oven; the residue was then dissolved with gentle heat in 26 cc. water, filtered, and sugar in filtrate estimated with Fehling's solution (1. cc. = 0.005 grm.). 2.7 cc. of the filtrate contain 0.025 grm. sugar.

EXP. XXXVI. 0.1 grm. sugar dissolved with mucus from frog's stomach in water, dried over water bath, residue dissolved in 20 cc. water, filtered, and sugar estimated in filtrate. (1) 2.05 cc. = 0.01 grm. sugar; (2) 2.1 cc. = 0.01 grm.

EXP. XXXVII. 0.2 grm. sugar dissolved in water with contents of frog's stomach, dried in water oven, residue dissolved in water, filtered (during which some was lost), and diluted to 25 cc. As the sugar was only 97 per cent., instead of 0.2 grm. only 0.194 was actually used.

1.75 cc. of filtrate = 0.01 grm. sugar.
25 cc. of filtrate = 0.143 grm.

The missing 0.051 probably lost when filter upset.

The same filtrate was examined in a 1 decimeter tube of Laurent's polarimeter, and gave rotation of the right of 2.8°. As 100° = 20.51 grm. sugar in 100 cc., 2.8° = .143 grm. in 25 cc., or precisely the same result obtained with Fehling's test.

EXP. XXXVIII. Frog. Pylorus ligated; 0.25 grm. undissolved sugar introduced through a glass tube into stomach. After 28 hours contents of stomach = 2.2026 grm.

Water	2.1663
Solids	0.0363
	2.2026

Residue dissolved in water, filtered, and diluted to 15 cc.

(1.) 3.55 cc. = 0.005 grm. sugar.
(2.) 3.7 cc. = 0.005 grm. sugar.

Water poured out into stomach = 2.1663
Sugar absorbed from stomach = 0.225

A little sugar was found in the water in the dish in which the frog was kept; perhaps it came from the urine. The peritonæum was distended with fluid.

EXP. XXXIX. Frog. Pylorus ligated; an opening was made in the lower part of the œsophagus, and the stomach emptied and dried with absorbent cotton. A glass tube was then pushed into the stomach through the opening in the œsophagus, and 0.2 grm. sugar inserted through tube into stomach. The œsophagus was then tied on the gastric side of the opening. After 19 hours contents of stomach = 3.9013, faintly alkaline.

Water	3.7751
Solids	0.1262
	3.9013

Residue dissolved in water, filtered, and diluted to 20 cc. — 4 cc. = 0.005 grm. sugar.

Water poured out = 3.7751 grm.
Sugar absorbed = 0.175 grm.

EXP. XL. Frog. Pylorus and œsophagus ligated, and 0.2 grm. sugar given, as in Exp. XXXIX. Stomach empty. After 22 hours contents of stomach = 4.2637.

Water	4.0889
Solids	0 1748
	4.2637

Residue dissolved in water, filtered, and diluted to 20 cc. — 2 cc. = 0.005 grm. sugar.

Water poured out = 4.0889
Sugar absorbed = 0.150

EXP. XLI. In order to see if secretion of water was produced in the stomach by the manipulation necessary to introduce sugar the pylorus was ligated, and a glass rod inserted into the stomach through an incision in the œsophagus, and moved around about as much as the glass tube would be through which sugar was given. The œsophagus was then ligated. After 96 hours contents of stomach = 0.1031 grm.

Water	0.0999
Solids	0.0032
	0.1031 grm.

Three other similar experiments gave corresponding results: in one instance after 24 hours the stomach was absolutely empty. For the amount of secretion caused by ligation of pylorus, see Exp. XIII. et seq.

EXP. XLII. Frog. Pylorus and œsophagus ligated; 0.2 grm. sugar given as in Exp. XXXIX. After 24 hours contents of stomach = 0.5479 grm.

Water = 0.5156
Solids = 0.0323

0.5479

Residue dissolved in water, filtered, and diluted to 20 cc. — 12 cc. = 0.01 grm. sugar.

Water poured out = 0.5156
Sugar absorbed = 0.0184

EXP. XLIII. Frog. Pylorus and œsophagus ligated: 0.2 grm sugar given as above. After 48 hours contents of stomach = 1.9671 grm.

Water = 1.9011
Solids = 0.0660

1.9670

Residue dissolved in water and diluted up to 25 cc. Contained no sugar.

Water poured out = 1.9011
Sugar absorbed = 0.200

EXP. XLIV. Frog. Pylorus and œsophagus tied: 0.2 grm. sugar given as above. After 72 hours contents of stomach = 2.4398 grm.

Water = 2.3588
Solids = 0.0810

2.4398

Residue contained no sugar.

Water poured out = 2.3588
Sugar absorbed = 0.2000

EXP. XLV. Two frogs. Pylorus ligated and 0.2 grm. sugar given as above to each. After 24 hours, contents of both stomachs = 5.3280, alkaline.

Water	5.1771
Solids	0.1509
	5.3280

Residue dissolved and diluted up to 25 cc. — 4.5 cc. = 0.005 grm. sugar.

Water poured out	2.5885	in each frog.
Sugar absorbed	0.186	

EXP. XLVI. Two frogs. Pylorus tied and 0.2 grm. sugar given to each, as above. After six hours contents of both stomachs = 2.236 grm.

Water	2.098
Solids	0.138
	2.236

Residue dissolved and diluted to 25 cc. — 3.2 cc. = 0.01 grm. sugar.

Water poured out	1.049	in each frog.
Sugar absorbed	0.161	

EXP. XLVII. Frog. Pylorus ligated and 0.173 grm. sugar given as above. After three hours, contents of stomach = 0.862 grm.

Water	0.775
Solids	0.087
	0.862

Residue dissolved and diluted up to 25 cc. — 3.6 cc. = 0.01 grm. sugar.

Water poured out	0.775
Sugar absorbed	0.1036

EXP. XLVIII. Frog. Pylorus and œsophagus ligated and 0.2 grm. sugar given with 0.5 grm. water. After 20 hours contents of stomach = 2.1457 grm.

Water	2.0877
Solids	0.058
	2.1457

Residue dissolved and diluted to 25 cc. — 5 cc. = 0.005 grm. sugar.

Water poured out	1.5877
Sugar absorbed	0.175

EXP. XLIX. Frog. Pylorus and œsophagus tied and 0.2 grm. sugar and 0.5 grm. water given. After three hours contents of stomach = 0.9373.

Water	0.8013
Solids	0.136
	0.9373

Residue dissolved and diluted to 25 cc. — 2 cc. = 0.01 grm. sugar.

Water poured out	0.3013
Sugar absorbed	0.075

EXP. L. Frog. Pylorus and œsophagus tied: 0.5 grm. water and 0.2 grm. sugar given. After six hours contents of stomach = 2.0088 grm.

Water	1.9230
Solids	0 0868
	2.0098

Residue dissolved and diluted to 25 cc. — 5 cc. = 0.01 grm. sugar.

Water poured out	1.423
Sugar absorbed	0.150

EXP. LI. Frog. Œsophagus and pylorus tied: 0.2 grm. sugar and 0.5 grm. water given. After 27½ hours contents of stomach = 4.1065 grm.

Water	3.9165
Solids	0.1900
	4.1065

Residue dissolved and diluted to 25 cc. — 22 cc. = 0 195 grm. sugar.

Water poured out	3.4165
Sugar absorbed	.195

EXP. LII. Frog. Œsophagus and pylorus tied: 0.9 grm. water and 0.182 grm. sugar given. After three hours contents of stomach = 1.403 grm.

Water	1.275
Solids	0.128
	1.403

Residue dissolved and diluted to 20 cc. — 1.7 cc. = 0.01 grm. sugar.

Water poured out	0.375
Sugar absorbed	0.065

EXP. LIII. Frog. Pylorus and œsophagus tied: 0.9 grm. water and 0.182 grm. sugar given. After six hours contents of stomach = 1.6242 grm.

Water	1.4770
Solids	0.1472
	1.6242

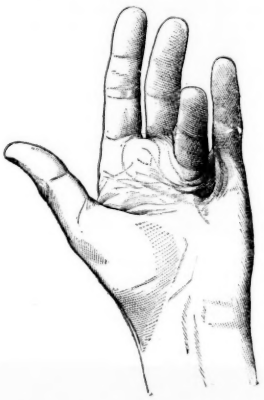
Residue dissolved and diluted to 25 cc. — 2.25 cc. = 0.01 grm. sugar.

Water poured out	0.5770
Sugar absorbed	0.071

EXP. LIV. Frog. Pylorus and œsophagus tied: 0 9 grm. water and 0.182 grm. sugar given. After 18 hours contents of stomach = 1.6223 grm.

Water	1.0353
Solids	0.5870
	1.6223

Residue dissolved and diluted to 20 cc. — 11.5 cc. = 0.01 grm. sugar.



Water poured out	0.1333
Sugar absorbed	0.1700

A CASE OF DUPUYTREN'S CONTRACTION.

BY EMERSON WARNER, M. D., WORCESTER, MASS.

G., a clergyman of distinction throughout New England and beyond, had been affected with this disease since he reached the age of forty. He is tall and slender, and of a bilio-nervous temperament. He has not for years enjoyed the best of health, yet has been able most of the time to perform pulpit service. The trouble in his hand began first as a feeling of soreness and hardness in the palm of his right hand. It slowly increased till it involved the little, ring, and middle finger of each hand, causing a marked deformity, flexing and drawing the fingers forward towards the palm of the hand, wrinkling and hardening the skin over

the metacarpo-phalangeal joint. Four years after the right hand began to be affected the left hand first showed signs of trouble. The ring finger of this hand was attacked, and it suffered more from contraction than the fingers of the right hand. At the middle phalangeal joint the finger made nearly a right angle. This was an awkward deformity for a public speaker to be continually thrusting into the face of his hearers. It was difficult to put on gloves, and in every way it was a more or less painful annoyance.

He had often applied for help, not only to the writer but to many another surgeon, but only to be told that nothing could be done. He had made up his mind to endure this state of things, and constantly and surely,

though slowly, growing worse until, perchance, amputation of one or more fingers might give the only relief which he could obtain.

About the beginning of the present year he called my attention to the work of Mr. William Adams on this subject, of which he had learned through a gentleman in Philadelphia, who had been operated by Dr. Keen of that city. So far as we then knew this was the only operation, as described by Mr. Adams, that had been done in this country. He asked that this operation might be done for his relief.

On the first day of March I operated upon his left hand, choosing this first as only one finger was involved. I used a very small knife, used mostly by oculists, consisting of little more than a very sharp point and a cutting edge. A sufficient number of subcutaneous incisions were made to cause the deformity to disappear. The finger at once appeared natural, was easily flexed, and took its place beside the other fingers, ready for duty, as though never crippled or in any degree disabled. It was laid on a splint, and an antiseptic dressing applied. The next day he was perfectly comfortable, and went about as usual, except that he did not leave the house.

On the 15th of March, two weeks later, he submitted to operation on the right hand. He then could use his left hand, and on the first Sunday in April he assumed the pulpit duties of a Brooklyn pastor who had been granted a three months' furlough. The patient feels himself relieved of a very serious deformity, and I see no reason why he should fear its return.

As the history shows, this disease occurred in a clergyman in middle life, and, so far as known, it was not caused by any injury, nor can it surely be traced to a strangely marked gouty diathesis. He has a brother, a little younger, who is suffering slightly from the incipient stage of the disease, but there is as yet no deformity.

On March 25th of the current year Mr. Noble Smith read a paper on this subject before the Royal Medical and Chirurgical Society of London. April 17th Dr. Robert Abbe read a paper before the New York Academy of Medicine on the same subject. Thus does the subject receive a new impetus at about the same time in these widely separated localities.

Reports of Societies.

MEETING OF THE AMERICAN GYNECOLOGICAL SOCIETY.

THE ninth annual meeting of the American Gynecological Society was held at Chicago Tuesday (September 30th), Wednesday, and Thursday. The meetings were held at the Palmer House, the President, DR. ALBERT H. SMITH, of Philadelphia, presiding. Twenty-three Fellows were present.

DR. W. H. BYFORD, of Chicago, the chairman of the Committee of Arrangements, delivered a brief address of welcome, in which he touchingly alluded to the great loss the Society had sustained since its last meeting in the death of Dr. J. Marion Sims.

DR. JOHN C. REEVE (Dayton, Ohio), presented a paper on several

MOOT POINTS IN REGARD TO INVERSION OF THE UTERUS.

Several cases were cited tending to prove that it was possible for uterine inversion to occur without the influence of pregnancy or an existing uterine tumor, and that, while inversion usually begins at the fundus, it oftentimes happens that the inversion begins with the

cervix. The cases which he had observed also demonstrated the fact that, although an inversion occurring during the puerperal state usually takes place immediately after delivery, it may occur several days later. He also cited several cases in which an inversion had occurred unaccompanied by those symptoms which are usually considered inseparable from such an accident. In the discussion which followed corroborative evidence was given by Drs. Byford, Sawyer, and Howard.

DR. H. P. C. WILSON (Baltimore) read a paper on

FOREIGN BODIES IN THE ABDOMEN AFTER LAPAROTOMY,

in which he gave a summary of twenty-one cases, six occurring in this country and fifteen in Europe, in which a foreign body, usually a sponge, had been left behind within the abdominal cavity. Among the cases cited was one occurring in his own practice in which he had removed an ovarian tumor from a patient between five and six months advanced in pregnancy. A miscarriage occurred on the eighteenth day after the operation. After a tedious convalescence the patient so far recovered as to go to her home in the country. Soon after she began to develop abdominal symptoms, and five months later a piece of sponge worked its way to the surface, and was removed; the local symptoms subsiding and the patient making a complete recovery. He believed that operators did not use sufficient care to avoid such accidents, and advised that, in all such operations, as few instruments and sponges as possible should be used; the sponges should be selected with especial reference to their perfectness, strength, and softness; that no divided sponges should ever be used; the instruments should not be too small, and there should be as few assistants as possible.

DR. THOMAS said that in four hundred cases of laparotomy he had only seen this accident happen once. The patient had presumably a cancer of the spleen and Bright's disease. An exploratory incision was made, the diagnosis verified, and the incision sewed up. In this case ether was used, which he would not advise at the present time, as he was convinced that, in cases of renal disease, a cessation of urinary secretion follows the use of ether, an accident which never follows the use of chloroform. In this case not a drop of urine was secreted after the administration of the ether, and the patient soon became comatose and died of uræmic poisoning. At the autopsy a piece of sponge was found in the abdominal cavity. So great was the liability to leave a sponge behind that he now always used sponges to each of which a tape, six inches in length, was attached.

DR. DUNLAP recommended the making of a long abdominal incision, which heals as readily and as perfectly as a short one, and helps to prevent the occurrence of foreign bodies being left within the abdominal cavity.

DR. MUNDÉ thought great care should be taken not to use friable sponges or those which had torn or roughened edges. In the final clearing out of the abdominal cavity sponges attached firmly to sponge-holders only should be used. During the discussion seven new cases were reported by different members in which some foreign body had been left behind by the operator.

At the afternoon session DR. C. D. PALMER, of Cincinnati, read a paper on the

VALUE OF ABDOMINAL SECTION AS A MEANS OF DIAGNOSIS.

Tapping had been shown by statistics to be a far more dangerous procedure, and at best only gives us an idea of the contents of the tumor, but no information as to its surroundings or even, in many cases, its location. The abdominal section was comparatively harmless except in cases of cancerous subjects.

DR. WILSON agreed with the writer, and cited the case of a patient in whom he had made an exploratory abdominal incision and found the case to be one of amniotic dropsy. The wound was sewed up, the os uteri dilated, and six gallons of amniotic fluid withdrawn, and the uterus cleared of its contents. In two weeks the patient was well.

DR. ENGELMANN did not agree with the reader in believing the operation any more dangerous in cancerous than in non-cancerous subjects.

VAGINAL ENUCLEATION OF CERVICAL FIBROIDS.

DR. PAUL F. MUNDÉ (New York) read a paper in which he strongly advocated the vaginal enucleation of cervical fibroids when they were a cause of dystocia. As proof of his statement he reported a case in which he had removed under such circumstances a very large fibroid, weighing three pounds, and gave a summary of nine cases he had collected, in all of which the mother recovered, and of the five viable children three were born alive; while of thirty cases of Cæsarean section, performed under similar circumstances, twenty-four of the mothers had died and sixteen of the children had been lost.

WEDNESDAY.

The discussion of Dr. Mundé's paper was opened by DR. JENKS, who cited a case in which he had removed a small fibroid by enucleation.

DR. BYFORD thought it was better in all cases of uterine tumors to wait until labor came on. Enucleation performed earlier exposes the mother to the same danger as if done at the time of labor, but gives rise, in addition, to the great probability of a miscarriage.

DR. VAN DE WARKER had seen, in consultation, a case which had been thirty hours in labor, and in which the pelvis was filled with a fibroid of the posterior cervical wall. He advised enucleation, but was overruled. Cæsarean section was performed, and the mother died of shock. The autopsy showed that enucleation could have been easily performed. In this case the child was saved.

DR. REAMY had enucleated a tumor in one case, and both mother and child had done well. The operation, he believed, should be done at the time of labor, for he was convinced that patients were less liable to sepsis at that time.

In closing DR. MUNDÉ thought that many circumstances should decide the time of the operation, such, for example, as the growth of the tumor, its location, and general characteristics.

EXTRA-UTERINE PREGNANCY.

DR. THOMAS (New York) presented a report of six cases of extra-uterine pregnancy, being a supplementary report to that read by him two years ago in Boston, in which he reported twenty-one cases. These cases were reported in detail, and illustrated many points in the diagnosis and treatment of this rare acci-

dent. The reader dwelt on the necessity of early making out a diagnosis, since in these cases delays are dangerous, and prompt action an absolute necessity. An operation should never be performed at full term simply because there is a fœtus in the abdomen, but only when the presence of that fœtus is causing trouble. The better plan is to wait until atrophy of the placenta has taken place. If the child is alive in the abdomen at full term of course it should be removed even at the increased risk to the mother. In the electric current we have the best agent for infanticide, which is the first step towards recovery. Up to the fifth month this should always be used in preference to a resort to the far more dangerous procedure of laparotomy. In cases where the fœtus is in the tube rupture takes place within the first four months. After that the fœtus is probably within the abdominal cavity, and whenever its presence there has been clearly made out electricity should be used unless the child is alive, in which case the patient should go to full term, and then laparotomy is indicated. The weaker forms of electricity should first be used, although it was astonishing how powerful a current had proved, in some cases, harmless to the fœtus as well as the mother.

DR. MUNDÉ reported a case in which he had operated successfully. He preferred to use the faradic rather than the galvanic current, believing it to be safer and equally efficacious.

DR. WILSON reported a case of a woman pregnant with twins. The one in the uterus was delivered at term, and the one in the abdomen was delivered by laparotomy a month later, — both children living.

DR. BAKER, in support of some of the facts brought forward in Dr. Thomas's paper, namely, the difficulty of diagnosis before the third month and the danger of aspiration in cases of hæmatocele complicating the pregnancy, reported four cases, three of which were seen in consultation. The first was a patient in whom all the rational signs of extra-uterine pregnancy were present, and ether was given in order to confirm the diagnosis by physical examination. Two days before there had been symptoms of internal hæmorrhage, with almost collapse, but the patient having recovered sufficiently the attempt was made with the anæsthetic. The examination failed to substantiate the diagnosis, and the patient sank while under the ether and died. The autopsy showed tubal pregnancy of six or seven weeks' standing, with an unruptured sac, and about two quarts of blood within the peritoneal cavity, hæmorrhage having occurred from a small vessel at the end of the tube. It would have been a perfect case for laparotomy had the diagnosis been made earlier. In another case aspiration of a post-uterine tumor supposed to be hæmatocele gave bright blood, which contra-indicated further operation, and the patient died from exhaustion in two or three days. An autopsy showed a rupture of the tube, with hæmorrhage and escape of a three months' fœtus within the abdominal cavity. The remaining two cases recovered, though not owing to any special skill of the reporter. One was a patient operated on for sterility, who became pregnant within two months after leaving the Free Hospital for Women, but the site of the pregnancy was a left tubo-interstitial one. The fœtus died in the fifth month, and has since remained encysted, gradually shrinking to about one third of its greatest size. The last case was seen about four years after the death of the fœtus, which had apparently taken place at the sixth month. The fœtal parts could be distinctly felt. No operative interference was advised, and the encysted fœtus has remained, occasioning little if any inconvenience. This patient has within eighteen months given birth to a child in the most natural manner.

DR. MAURY (Memphis) read a case of

TUBAL PREGNANCY,

with subsequent rupture of the sac. He believed it was a great mistake to operate at the time of the rupture, but that we should always wait until the period of shock was passed.

DR. MUNDÉ read a paper on

THE LIMITS OF VAGINAL HYSTERECTOMY FOR CANCER,

illustrated by two cases. The paper was in answer to one read last year by Dr. Jackson, in which the writer had pronounced the removal of a cancerous uterus an unjustifiable procedure. In the first of the two cases reported by Dr. Mundé the patient recovered from the operation. A recurrence of the disease took place in nine months, although the patient is still alive. In the second case the disease was found to have spread to the vaginal wall, and the patient died of shock from internal, concealed hæmorrhage. Dr. Mundé agreed with Dr. Jackson that, owing to patients' unwillingness to submit early to examinations a diagnosis was often impossible until the disease was too far advanced. He disagreed entirely with the second statement of Dr. Jackson, that the operation was only for amelioration. He had collected the reports of eighty-two operations. In forty-eight the disease had recurred in from two months to two and a half years, while in thirty-two cases there had been no recurrence. In other words, 39.2 per cent. of patients in whom the operation had been performed early, over one third, had been free from any recurrence for at least two years or more. He believed that the operation should be confined to a small class of cases, to those where the cancerous degeneration was limited to the uterus, and in that organ had extended up beyond where the operation of incision could be performed; where there was perfect freedom of uterine motion, the vagina capacious, and the patient in good condition to withstand the shock of the operation, although this was comparatively slight. As regards the danger of the operation, its fatality was constantly becoming less as operators were becoming more experienced. Out of 256 cases which he had collected there had been sixty-two deaths, or 24.6 per cent.

In reply to the paper, DR. JACKSON said all operations must be judged by the principles underlying them. All surgical operations should be done either to relieve suffering or to prolong life. This operation, he claimed, did neither. It lessens the sufferings only of those whom it kills. The recurrence of the cancer brings with it the same suffering and the same death. Cases of cancer unoperated have lived fully as long as those on whom the operation has been performed. He felt confident that the area of the operation was a very limited one and would become more so. Removal can be accomplished far less dangerously by other means, and with equally good results.

DR. VAN DE WARKER thought there were other and safer ways of operating. It must be very rare, in his opinion, that the extirpation removed beyond the line of infiltration. He thought in examining the figures read by Dr. Mundé that the cases of recurrence should be considered with reference to whether the

patients were menstruating or had passed beyond the climacteric; for there is a marked tendency in the first class of cases to recur which does not obtain in women later on in life.

DR. ENGELMANN agreed with Dr. Mundé *in toto*. It is an operation which should be fairly tested. The statistics are improving. Time has not elapsed sufficiently to show how long these patients in whom it has not yet recurred are going to be free from a recurrence. The whole thing is *sub judice* and not warranting Dr. Jackson's wholesale condemnation.

DR. PALMER agreed that the mortality caused by the operation will doubtless be still further reduced; but the impossibility of diagnosticating the extent to which the cancer has extended will rule out the operation.

DR. BAKER alluded to six cases which he had previously reported to the Society, in which he had operated by a method fully described in the *American Journal of Obstetrics* for April, 1881. Five of these patients are still well, from four to six years having elapsed since the operation, while the remaining one has succumbed to a return of the disease after a respite of about three years.

DR. REAMY claimed that the operation does not prolong life. Statistics are needed to show how long patients live with cancer in whose cases no operation is performed. The disease will be found to have extended into the tissues so far that recurrence is sure to come. The operation can be done more safely than heretofore, but the statistics do not prove that life is prolonged, and he agreed with Dr. Jackson that the operation was unwarranted.

DR. MUNDÉ closed the discussion by repeating the main points of the paper, which he considered had not been answered.

THURSDAY.

At the opening of the morning session the President, DR. ALBERT H. SMITH (Philadelphia), delivered the annual address, taking as his subject

THE PRESENT ASPECT OF THE PUERPERAL DISEASES.

The paper was largely historical, and gave in detail the present position held by observers at home and abroad. The writer favored the continued use of antiseptics, and insisted on the great value and harmlessness, when properly used, of intra-uterine injections.

DR. SAWYER (Chicago) made some remarks on

THE OCCIPITO-POSTERIOR POSITION IN VERTEX LABORS,

illustrating his paper with an analysis of thirty-five cases. He claimed that the occiput presented much more frequently posteriorly than was supposed, and that rotation forward was the exception and not the rule. He favored the rotation either by the hand introduced within the vagina or by long forceps whose handle was a curve continuous with the curve of the blade.

DR. RICHARDSON differed entirely from Dr. Sawyer. He agreed with him that these positions were among the most troublesome to be found in obstetric practice. He, however, believed that in all cases, if the flexion of the head was complete, the occiput would rotate forward. Where it does not, as in Dr. Sawyer's cases, it was either because the head was partially extended or because the presenting part had not yet reached the floor of the pelvis. The treatment in these cases should be to flex the head either manually or by the introduction of the ordinary forceps with the pelvic curve downwards instead of upwards. In the vast majority of cases all will then go well. There was no call for special forceps for such cases.

DR. REAMY did not agree at all with Dr. Sawyer either as to the frequency of these cases or their failure to rotate forward. In all cases as soon as the position is known, and the os sufficiently enlarged, correct the misplacement in the absence of a pain with the forceps — the straight-handled forceps being just as good as this new curved pair.

DR. HOWARD recommended the use of Tarnier's forceps in these cases.

DR. ENGELMANN thought that too much stress should not be laid on the instrument, but on the necessity of a judicious use of any forceps in the hands of the operator.

DR. SMITH totally disagreed with Dr. Sawyer on the several points on which the paper was based, and agreed with the other speakers on the facility with which the head can be rotated, even in those rare cases in which a failure of rotation has taken place.

AN INSIDIOUS AND FATAL FORM OF SEPTICÆMIA.

DR. ENGELMANN (St. Louis) read a paper giving the account of several cases in which a most insidious and fatal form of septicæmia was developed. They were cases in which, in the absence of the usual symptoms, intuition and not medical skill seemed to be our guide. There was in all a marked absence of either fever or pain. The danger seemed greatest where the symptoms were least, or even wanting. A slight diarrhœa and a possible elevation of temperature to a degree were the only symptoms. Neither the temperature nor pulse revealed the cause of the fatal result which followed in all the cases. The cases were non-puerperal and puerperal.

DR. RICHARDSON confirmed the statement of the reader, and alluded to several cases of puerperal origin in which he had noticed this same absence of the usual symptoms of septicæmia. There was in all his cases at first a day or two of suspicious symptoms, but after these had passed there were left only a slight diarrhœa and what he had noted in all the cases, a well-to do mental condition, the patient always considering themselves as "well." The marked progressive general failure alone showed the mischief.

DR. REAMY confirmed the opinion of Dr. Engelmann, and said that all cases in which there was an abdominal distention without pain but with a diarrhœa he looked upon with suspicion.

DR. JOHNSON cited a case in which death had occurred on the ninth day after delivery, in which all the symptoms were as Dr. Engelmann had described.

PAPERS READ BY TITLE.

The following papers were read by their titles:—

The Hygiene of Pregnancy, by Dr. Samuel C. Busey, Washington.

Rapid Dilatation of the Cervical Canal, by Dr. Wm. Goodell, Philadelphia.

The Physiognomy of the Vulva as a Sequence of Anal Disease, and the Cause or Sustaining Cause of Uterine Disease, by Dr. Isaac E. Taylor, New York.

The Early History of the Treatment of Vesico-vaginal Fistulæ in the United States, and the Statistics of the Several Modes of Operating, by Dr. Nathan Bozeman, New York.

Contributions to the Topographical and Sectional Anatomy of the Female Pelvis, by Dr. David B. Hart, Edinburgh.

Fibro-myomata and Fibro-cystic Myomata of the Uterus — their Diagnosis, Prognosis, Pathology, and Treatment, with Cases and Specimens, by Dr. R. S. Sutton, Pittsburg.

The Ring of Bandl, by Dr. W. T. Lusk, New York.

The new President, Dr. Howard, was introduced to the Society, and the meeting adjourned.

THE BUSINESS MEETING

was held Wednesday evening at half-past eight o'clock. The limit of membership was changed from sixty to one hundred. It was voted to hold the next meeting at Washington on the last Tuesday but one of September and the following Wednesday and Thursday.

Dr. George E. Bantock, of London, was elected an Honorary Fellow.

ELECTION OF OFFICERS.

The following officers were elected: —

President: Wm. J. Howard, of Baltimore.

Vice-Presidents: Wm. L. Richardson, of Boston; Paul F. Mundé, of New York.

Secretary: Frank P. Foster of New York.

Treasurer: Matthew D. Mann, of Buffalo.

Council: Joseph T. Johnson, of Washington; A. Reeves Jackson, of Chicago; H. P. C. Wilson, of Baltimore; E. Van de Warker, of Syracuse.

MASSACHUSETTS MEDICAL SOCIETY.

COUNCILORS' MEETING.

A STATED meeting of the Councilors was held at the Medical Library, Boston, on Wednesday, 1st inst., at eleven o'clock A. M. The meeting was called to order by the President, DR. CHARLES D. HOMANS.

APPOINTMENT OF DELEGATES.

Delegates to other State medical societies were appointed as follows: —

Vermont, DRS. A. M. SMITH, of Williamstown, N. S. BABBITT, of North Adams.

New York, DRS. A. C. DEANE, of Greenfield, F. K. PADDOCK, of Pittsfield.

THE SHATTUCK PRIZE.

The Committee on Publications reported, through DR. HODGES, that the Society's prize fails to induce competition, and the committee has, therefore, decided to request that instead of the prize as now offered the income of the Shattuck Fund be appropriated for the objects set forth in the terms of the bequest of the donor. The following resolution was presented by the committee: —

Voted, That the Committee on Publications be directed and authorized to offer a prize of $1000 for an essay on the Climate and its Modifications as Influencing Health and Disease, or on any of the diseases of the inhabitants of New England, or on any kindred subject, such essay, with a sealed envelope containing the author's name, to be delivered to the chairman of the Committee on Publications on or before the first day of March of the year 1888. It is understood that such prize shall be given at the annual meeting of that year, and only to an essay deemed worthy of it by the committee.

After discussion the report of the committee was accepted, and its recommendation adopted.

THE NORFOLK SOUTH DISTRICT MEDICAL SOCIETY.

The committee to which was referred at the previous meeting the petition for the establishment of the Norfolk South District Medical Society, to consist of Fellows of the Society residing in the towns of Quincy, Braintree, Randolph, Holbrook, Weymouth, Hingham, and Cohasset, reported through its chairman, DR. HODGES.

The report stated that the District Societies of Norfolk and Plymouth, duly and individually notified, were ably represented at a hearing on July 11th, and the proposal was discussed in detail by those present. The committee recommended that the prayer of the petitioners be granted. This recommendation was adopted by the Council.

CHANGES IN COMMITTEES.

By the resignation of DR. WELLINGTON from the Committee on Finances the following changes were made in Standing Committees: —

DR. FRANCIS MINOT was transferred from the Committee on Membership and Resignations to the chairmanship of the Finance Committee, and DR. JOSEPH STEDMAN was appointed to fill the vacancy thus made in the Committee on Membership and Resignations.

MEDICAL DIPLOMAS. — BOARDS OF CENSORS.

The following, offered by DR. H. P. BOWDITCH, as amended by Dr. Minot, was, after discussion, adopted: —

That the Standing Committee on Medical Diplomas be requested to consider and report at the next meeting on the propriety of adding to the list of recognized colleges the names of the following medical schools: University of Berne. University of Zurich. Woman's College of the New York Infirmary. Woman's College of Pennsylvania. Medical School of Paris. And also the names of any other regular schools which may be referred to said committee by any Councilor as graduating or having graduated women as physicians, whether such school be American or foreign.

That the committee also take into consideration diplomas of foreign medical colleges as evidences for admission into the Society.

In the discussion on the adoption of the above resolution, DR. REYNOLDS remarked that, in his opinion, years of study and success as practitioners should count for something, as well as the passing of an examination, in admission to the Society, and he believed that by a single Board of Censors the object of the Society, to discriminate between those who are fitted to practice medicine and those who are not, would be more likely to be attained than by the present method of admission by several Boards.

In approval of these remarks DR. HAZELTON offered the following: —

That a committee of five be appointed by the Pres-

ident to consider if it be proper to take steps to change the Constitution and By-laws in regard to the Boards of Censors.

DR. BRONSON said that the remarks of Dr. Reynolds were exceedingly pertinent and worthy of attention. The change proposed would be of immense advantage to the Society.

DR. DUDLEY stated that two years ago he was a member of a committee which had this subject before them. They found that to institute such a change it would be necessary to have the Charter altered by the Legislature.

DR. HARVEY argued that the fact that the subject has been one of inquiry by committees shows the present methods not to be satisfactory.

After further discussion DR. HAZELTON'S motion was adopted, and the committee was instructed to report at the next meeting.

The following were appointed to constitute the committee: Drs. I. H. Hazelton, J. P. Reynolds, J. C. Gleason, E. H. Bradford, E. B. Harvey.

HONORARY MEMBERS.

DR. BRONSON called attention to the statement made at the annual meeting of the Society, that of late years all honorary members of the Society had been illegally elected, and asked if such is the case.

In reply the By-law was read regarding the election to honorary membership, and it was stated that its provisions had been complied with.

Adjourned at 12.15 P. M.

CHICAGO MEDICAL SOCIETY.

LISTON H. MONTGOMERY, M. D., SECRETARY.

STATED meeting, September 15, 1884. DR. D. A. K. STEELE, President.

CONGENITAL MALFORMATION OF THE STOMACH. — EXHIBITION OF BONY TUMOR OF PELVIS. — RESOLUTIONS IN BEHALF OF THE NATIONAL BOARD OF HEALTH LOOKING TO SANITARY MEASURES FOR THE RESTRICTION OF CHOLERA, YELLOW FEVER, ETC.; APPOINTMENT OF COMMITTEE. — MEDICAL DEPARTMENT OF THE PUBLIC LIBRARY.

The following scientific and other important business as announced was transacted: —

DR. C. W. EARLE read a brief paper on Congenital Malformation of the Stomach, and presented the stomach of an infant that lived for twelve days on the minutest quantity of nourishment. The autopsy revealed that no opening existed between the stomach and duodenum, nor was there a pylorus. It was ascertained, however, that biliary matter had been discharged in the fæces. The same gentleman also read a report of a case of Bony Tumor of the Female Pelvis, and exhibited the pathological specimen, which weighed three pounds and a half. Both specimens were regarded as being rarely seen, and the cases were informally discussed, after which the Secretary, DR. LISTON H. MONTGOMERY, presented the following preamble and resolutions, and moved their adoption: —

Whereas, From present reports and indications in foreign countries cholera and yellow fever (both pestilential diseases) prevail, and as the latter especially is always assuming a threatening attitude toward us, and is not conducive to our national prosperity nor to public health, and should, if possible, be averted with earnest and efficient sanitary measures, and

Whereas, Cholera may make its appearance on this continent ere another twelve months should elapse, and should likewise, if possible, be averted or restricted to the narrowest limits, therefore

Resolved, That it is the sense of the Chicago Medical Society to have that department of the government relating to public health recognize the services of able sanitarians who constitute the National Board of Health for the purpose of coöperating with municipal, State, and other organizations of a similar kind, and that a committee of seven (7) members of this Society be appointed by the Chair to draft suitable resolutions in behalf of said National Board.

Resolved, Furthermore, that this committee present said resolutions to the Congress of the United States, memorializing that body to make a sufficient appropriation for the purpose of said Board for scientific investigation in the prevention and restriction of epidemic, preventable, and pestilential diseases.

We believe this action should be promptly taken at the coming session of our National Legislature, and that a thorough sanitary organization of the nation should be recognized, and with it absolute enforcement of the best means for the protection of her citizens and the improvement of our inter-State sanitary condition.

The mover of the resolutions stated that inasmuch as they had been published on the postal card announcements every officer and member of the Society, which consisted of 276 members, had (he presumed) become familiar with their reading. He desired that there be an extended discussion, and that every one present their views upon them. The motion to adopt was promptly seconded by Drs. R. E. Starkweather and H. J. Reynolds. They evoked much discussion. Among those who participated were Dr. E. Andrews, Dr. J. A. Robison, Dr. J. H. Etheridge, Dr. W. H. Curtis, Dr. H. A. Johnson, Dr. J. H. Hollister, Dr. G. H. Chapman, Dr. P. M. Woodworth, Dr. C. E. Webster, Dr. John Bartlett, each of whom favored their adoption. Upon call of the question the motion to adopt unanimously prevailed.

The PRESIDENT arose to state that he desired a little time to complete the committee, which he regarded as an important one.

DR. E. ANDREWS moved, duly seconded by Dr. C. E. Webster, "That this Society hereby express its thanks to Dr. Vincent L. Hurlbut for the gift of a very valuable collection of books and pamphlets, consisting of 300 volumes, to the Library Committee of the Society for the Chicago Public Library." The speaker also stated, in behalf of the Library Committee, that there are on the shelves of the City Library 1200 volumes for medical reference. The Library have bound, at their own expense, seventy-five volumes, all of which shows favorably for the short period of a few months since the plan of establishing a medical department in this direction was begun. After various inquiries as to the last donation had been answered, the motion to thank Dr. Hurlbut was heartily and enthusiastically unanimous.

The PRESIDENT announced the following gentlemen to serve on the committee provided for in Dr. Montgomery's resolutions: —

Dr. O. C. DeWolf, Dr. R. E. Starkweather, Dr. L.

H. Montgomery, Dr. John Bartlett, Dr. J. H. Etheridge, Dr. A. R. Jackson, Dr. J. H. Hollister.

DR. H. A. JOHNSON asked to be excused from the committee for the reason that he was the representative from Illinois on the National Board of Health. He extended an invitation, however, for the committee to call upon him at his library at any time when convenient to do so, and he would afford its members all that he could in the direction of his experience. His books also were at their disposal.

The invitation was accepted with thanks.

DR. J. H. ETHEPIDGE moved, duly seconded, that this committee be authorized to present *their* resolutions to the Society for a final consideration, and then to be submitted to Congress, as expressed in the resolutions, which motion carried, and was so ordered.

The Society then adjourned.

Medical and Surgical Journal.

THURSDAY, OCTOBER 9, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

MEDICAL BEQUESTS.

How a physician in America shall bestow his money so as to give the greatest possible benefit to his fellow men is a question that arises naturally in the mind as one reads in the daily papers the accounts of the testamentary provisions of various good physicians who have left behind them a sufficient amount of this world's goods to make its disposal worthy a newspaper item. Certainly it is proper that special thought should be bestowed upon the subject, and that the matter should not be considered in exactly the same light in which a non-medical man would look upon it. A physician has ordinarily done much to alleviate individual instances of distress; it seems but natural that he should desire to continue his peculiar work after he has personally ceased from his labors, and that can best be done not by giving directly to the poor and suffering but by increasing the efficiency of the race of physicians that follows after him. This he may do by seeing them provided with better means of education, and by that we do not refer simply to the education prior to the reception of the degree of M. D., but also to the education which should follow the doctor to the very end of his career.

Other people are sure sooner or later to furnish hospitals with the funds necessary for their support, looking upon them as a refuge for the sick — let the physician take that higher view of them as congregations of the sick where numerous examples of the same disease allow that disease to be studied for the benefit of all mankind, and see to it that the doctors are provided with those things necessary for the prosecution of their studies. The doctor desirous of perpetuating his good work should also bear in mind that in this free country private liberality must furnish those funds which in some monarchical countries are provided by the government. The funds of medical schools must here be provided by private liberality, and few medical schools in America are well endowed. The individual who assists in the endowment of any of the better class of schools is sure to do an action which will extend its good work for generations, and one which seems specially called for at the present time. There is here an abundant opportunity either to endow special chairs or to increase the general funds of the institution. Provision for the chair of Pathology in the Harvard Medical School has recently been made by the will of the late Professor Ellis, and our medical schools commemorate in the names given to various professorships the liberality of various physicians.

The establishment of medical libraries, or the encouragement of those already existing, is a matter that promises very great good to the profession. One cannot expect such libraries to be founded by other than medical men, or that general libraries shall pay special attention to a medical department, but a medical department for medical men might well be joined to a general library. Of such a library, Worcester, Mass., presents a favorable example.

A library may well be joined to a hospital. It was a most liberal act of the late Dr. Treadwell, of Salem, to establish the library connected with the Massachusetts General Hospital, which bears his name, and one for which his memory is held in grateful remembrance. No other hospital in Boston possesses more than the nucleus of a library.

The Boston Medical Library Association has never yet, we believe, received a legacy of money, though its usefulness might be very greatly increased by an endowment. It has received many valuable legacies in the shape of books, but one can well imagine that it suffers for want of funds.

We hope some time to see salaries attached to certain positions connected with hospitals. The pathologists should not be allowed much longer to do their work without pay. At present the pathologist must regard his labor as a matter of public charity or a stepping-stone to something else that will eventually reward him for his labor. However conscientious he may be in his work he is not properly situated to make it of the greatest benefit to the profession and the community. It is work which is laborious and exacting, and which ought to make a man a return in a more substantial shape than the bubble reputation, but which is not repaid. To be sure that position is often held by the occupant of a chair of pathology in a medical school, when a medical school is at hand, and in such cases it is, undoubtedly, useful to the professor, but hospitals are more numerous than medical schools. It is doubtful if the profession can be more benefited than by the encouragement of the study of pathology, and certainly a vow of poverty ought not

to be a necessity to those who devote themselves to it. That the pathologists themselves make no complaint does not invalidate the general truth of our statement.

The man who endows a hospital with a fund for the payment of a pathologist may not provide for its most obvious and immediate want, but he is doing that which in the end ought to make that hospital contribute to the sum total of human knowledge.

Various positions at the Johns Hopkins Hospital, which have clinical duties attached, are, we believe, to be paid: an example which may lead at some future time to a proper adjustment of the subject.

Our hospitals feel the need of funds for the furnishing of appliances without which the surgeon often feels that his work falls short of the great good he might accomplish. Few hospitals are fortunate enough to possess so elegant and complete an assortment of instruments as the Bigelow collection at the Massachusetts General, and the want of adequate means for furnishing crutches, trusses, and prosthetic apparatus is almost universal.

The lectureships which exist in England might profitably be more widely imitated in this country. They serve at once as incentives to those who aspire to hold them and to those who profit by hearing them.

Fellowships which should allow an occasional student who has given unusual proofs of ability an opportunity to increase his knowledge, by further study at home or abroad, would help to raise the standard of medical knowledge by increasing the number of well-informed individuals. The influence which a single individual possessed of an unusual fund of information may have upon a community can only be appreciated by those who have watched the career of such an individual.

Societies, of which the Massachusetts Medical Benevolent Society is an example, appeal loudly to the sympathies of those who know how few of the profession succeed in providing for their own old age or for the care of those dependent upon them.

What has been said makes it needless to add that we are not soliciting contributions for any medical charity or educational institution, but we have a feeling that medical men, with the self-abnegation which is so prominent a characteristic of the profession, feel it almost selfish to especially remember the needs of their brethren. We believe that contributions to the profession may well be regarded as contributions to the general welfare of mankind. The profession may be regarded not only as a national organization for almsgiving, but also, as we have recently been told in the pages of the Journal, as a popular educator. If one wished to convert a whole nation to certain doctrines what surer means could he find than the sending one or more disciples into every hamlet to be living examples of the principles to be inculcated. How careful would the promoters of such a scheme be to instruct their missionaries before sending them out and afterwards to keep them up to their work by supplying them with the latest information in the shape of books and periodicals, and by providing for regular meetings for consultation and social intercourse.

Such an organization exists already, and we doubt if there is a surer means of benefiting humanity than by strengthening it.

CHOLERA AND RAGS.

In April of this year the Treasury Department at Washington issued a circular forbidding the importation of rags from countries infected with cholera, and especially from Egypt, unless subjected to prescribed methods of disinfection.

In accordance with this circular an inspector was appointed at Cairo, and preparations were made at several ports of entry, — notably at Boston, — at a considerable outlay of money, for the detention and disinfection of cargoes of rags not treated at the point of departure.

August 30th the Treasury Department issued an order to collectors of ports prohibiting for three months all importation of foreign rags under any conditions. We were very skeptical of the wisdom or efficacy of the first circular, and are still more skeptical in regard to this second order.

It is not certain that cholera is never imported by rags, but we have yet to learn of an authenticated instance. Small-pox, as might be anticipated, is sometimes conveyed in this way, but even in regard to small-pox, investigations have shown that the cases caused by rags are much fewer and less frequent than would be anticipated from the character of the contagion in that disease. Dr. Bristowe, as medical officer of the Privy Council, visited eighty-six paper mills in different parts of England before making his report on this question in 1866, in which the conclusion was reached that small-pox and other infectious diseases are very rarely introduced into paper mills by rags. Even were the probability of an importation of cholera by rags much greater than it can fairly be claimed to be, why close this door and leave wide open so many others much more easy of entrance?

It would seem as if, possibly, the predictions of a general European outbreak of cholera have been made without taking sufficiently into consideration the great progress in sanitary science made in Germany and Great Britain since the last great epidemic, nearly twenty years ago, and more especially in the ten years succeeding the less widespread prevalence of cholera in 1873. Moreover, the fact that thus far, a year from the first appearance of cholera in Egypt, and six months after its recognition in Europe, its ravages have been confined to countries in which the conditions and regulations regarding the public health are a quarter of a century behind England and the greater portion of the United States, lends support to the view that the epidemic may be controlled without seriously menacing London and New York.

However, whether we need to take precautions against the introduction of cholera into this country or not, the recent regulations of the Treasury Department at Washington forbidding the importation of rags for three months into any port of the United States we regard as entirely uncalled for, and as

placing serious and unnecessary restrictions upon an important industry, namely, the manufacture of paper.

The rule has, apparently, been made from a fear that some rags may contain the cholera infection in a potentially active state, that these particular rags may come to us, and that if we receive them we may get the cholera with them, in spite of the fact that in the half century that cholera has been a menace to this country and to Europe not a single case can be instanced where it was introduced anywhere through the medium of rags.

We do not at the present time argue for or against the *cholera bacillus*, but we state the simple fact that cholera prevails only under lax local sanitary care, and in conditions of excessive filth. As was said by Sir Joseph Bazalgette, chief engineer of the London sewerage works, "the places formerly most favorable to the spread of the disease became quite free from it when afterwards properly drained."

Speaking for our own State, we do not hesitate to say that there is no reason for forbidding the importation of rags, except, possibly, from yellow-fever ports during the heat of summer.

There certainly is no surer way of bringing sanitary science into disrepute than by unreasonably obstructing commerce, trade, and manufactures.

MEDICAL NOTES.

— M. Beaunis, Professor of Physiology to the Faculty of Medicine at Nancy, records an extraordinary case in the *Gazette Méd. de Paris*, August 2, 1884. The patient was a girl aged twelve and a half years, and was suffering from her fifth attack of chorea. M. Beaunis had been informed by Professor Birnheim of the result of hypnotism in a similar case and decided to have it tried. The result was that as soon as the child was hypnotized all choreic movements ceased, and when asked to write, instead of meaningless scrawls, her writing was steady and legible. The seances were continued for some days and the child was cured completely.

— John P. Hankins, C. S., Brevet Major-General, U. S. A., writes in the *American Grocer* regarding canned foods and the experience of the army therewith, and says he has never known or heard of a case of poisoning by the use of canned goods in the army. As the result of his observations he concludes as follows: "Deductions from the foregoing may be fairly made, that the reports of poisoning by eating canned food are not to be believed, or are only to be believed when it may have occurred by reason of the person having eaten from a can the food in which was evidently spoiled, and so spoiled that the appearance of the can would surely have indicated the unsound condition of its contents to a person exercising ordinary care. If a person buys tainted meat from the butcher and eats it, knowing it to be a little *off*, and is taken sick, he must blame himself for trifling with his health; and likewise, if he buys canned food of suspicious appearance, he must expect to pay in health for his carelessness or temerity. Therefore, having no apprehension as to the method of packing an article, whether in tin or in glass, whether soldered with the aid of an acid or soldered inside or outside the can, there is every reason to consider canned articles as good for food as any food can be. The experience of our army ought to be conclusive on this subject. And no person having a decent knowledge of what is good or bad, sound or unsound, could be misled into eating an improper article from a can any easier than he could be induced to eat a decayed potato or a tainted piece of butcher's meat."

— Dr. Waxham, writing in the *Archives of Pediatrics*, speaks highly of the use of bismuth in rectal injection in cases of dysentery, claiming that it greatly abridges the ordinary course of that disease. From ten to twenty grains of bismuth are administered with mucilage of acacia and water after every evacuation, and if not sufficient in itself to control the frequent stools a little laudanum is added. Recently a child suffering from a severe attack of dysentery, with prolapse of the rectum with every passage, was almost immediately relieved. Within twenty-four hours the character of the passages was entirely changed, the tenesmus and frequent desire to stool relieved, and the prolapse did not recur after the second or third administration. This is only one of many cases where this remedy has been used with gratifying result.

— At the late meeting of the American Association for the Advancement of Science, in the Section on Economic Science and Social Statistics, Dr. Charles Warren, Statistician of the United States Bureau of Education, read a paper on the learned professions and the public, 1870–1880. Deriving the number of persons engaged in law, medicine, and divinity, from the occupation tables of the census, he showed that the rate of increase for each profession during the decade was much greater than the rate of increase in the general population. He commented upon the marked increase in the number of clergymen of foreign birth, and the great increase in lawyers, particularly in States situated north of the Potomac and Ohio rivers. Admitting that the number of clergymen is within the control of the sects purely, and not subject to legal interference, he observed that there is precedent for considering lawyers as officers of the State, and eminent propriety in making physicians also unpaid State officers. When this is done, the qualifications will be under State control, and indirectly the supply can be limited to actual needs. In 1880 he believes there was a surplus of sixty-four thousand in these three professions, and that decisive measures should be taken to remedy it.

— A correspondent of *Science* (October 3d) reënforces the stories of fasting pigs with an account of a hog which, imprisoned by a heap of driftwood after a flood, received no food whatever for forty-two days. Though much emaciated, it was able to drink eagerly of thickened milk, and rapidly recovered.

— An iodoform collodion is well spoken of, consisting of iodoform, ten parts, collodion, ninety parts. To be applied with a camel's-hair brush, the edges of the wound being held together until it dries. For wounds in exposed situations.

Correspondence.

"MILITIA AMBULANCE BEARER COMPANIES."

HEADQUARTERS FIRST BRIGADE,
MASSACHUSETTS VOLUNTEER MILITIA,
BOSTON, *September* 30, 1884.

MR. EDITOR, — I have read the article "Militia Ambulance Bearer Companies" in your issue of 25th inst., and should be pleased to aid in the formation of a corps such as you suggest.

Very respectfully, your obedient servant,
NAT. WALES, *Brigadier-General.*

Miscellany.

DOCTORS TRUMAN AND CROOKS.

EVERY member of the profession in the little city of Oldport — and there were a dozen of them, all eager for patients and for fees — felt sorry when Truman announced his intention of leaving the town to engage in a professorship in a neighboring city. To be sure it made one physician less, for a time at least, but Truman was regarded as an honorable competitor with whom all liked to labor. When Smith the carpenter fell from the new bank building, breaking his leg, Truman was called to attend him, in the absence of the family physician, Jones. For two days Truman rendered every needful attention to the unfortunate carpenter, and might have kept the case; there was nothing in the medical customs or ethics of Oldport that forbade it. He did not do this, however, and as soon as Jones returned home he drove around to his office to deliver over the patient to him; and absolutely refused to take any portion of the fee for his own trouble. This Jones always thought was doing as you would be done by.

Truman was once called in consultation with Dr. Damon, a young and struggling practitioner. He found dissatisfaction expressed which he did everything in his power to allay. The next day Truman was called on by the father of the patient, and urged to take the case. It would prove a lucrative one, and Truman certainly needed the money. The patron was ready and anxious to discharge Damon. Truman refused point blank to take the case, urging the father to continue the present attending physician, who was doing as well as anybody could do; and he so represented the case and Damon's entire competency to manage it that the family concluded to make no change, and they still employ Damon as their family physician.

Truman was never known by look or word to do anything to disparage a brother physician, and never sought to insinuate himself into other physicians' good families. And ever manifesting this excellent disposition to "live and let live," his departure was exceedingly regretted by all the medical fraternity of Oldport, who said that his name expressed his character, and that he was every inch of him a *true man.*

Far different were the feelings when Crooks arrived as his successor, and hung out his shingle in one of the prominent squares of the city. Crooks had brought with him an unsavory reputation from a neighboring town where he had been practicing. He was looked upon by his brother physicians as tricky and untrustworthy. He had a smooth speech and soft and winning manners, and seemed to your face a wondrous good friend, but when your back was turned his words proved poisoned arrows and even his gestures and his looks carried bane. He had but one end in view, to win practice, and to do it where he could by undermining other physicians. He was never known to speak unqualifiedly in praise of a brother practitioner, though he knew well how to "damn with faint praise," and "without sneering" to "teach the rest to sneer." People used to say that Crooks could express more by a look than many men could by a long harangue.

Certain it was that it was not regarded as safe to have a consultation with him, for somehow he always managed to come into possession of the case. There was a seeming agreement when the *confrère* was present, but before Crooks left the house he would manage to slip in a word of disparagement or even a hint that proved damaging to the attending physician; and there was, moreover, an air of superior wisdom about Crooks that impressed the family, and put the regular attendant at discount. He was called in consultation with Jones on a certain occasion. The case was one of simple pneumonia; there was no danger whatever. There was entire agreement as to diagnosis, and no apparent disagreement as to treatment. Jones suggested antimony, and Crooks remarked that antimony might be too depressing; the same end could be obtained by giving ipecac. Jones momentarily left the room for his medicine chest, and Crooks observed to the over-anxious family attendants, "antimony would infallibly kill that child." The two medical men walked home together, and Crooks was sweet, amiable, and condescending as usual. The next morning Jones received a message from the head of the family of his patient that his services were no longer required, as Crooks would take the case. One favorite trick of Crooks was to call on families where he had at some time been summoned in consultation. The consultation proved an excuse for a friendship and an intimacy that was undoubtedly profitable to him. The fraternity did not, however, regard this as fair dealing. In short, the opinion had more than once been expressed in medical circles that Crooks merited his name, and that he was a *bad crook.*

How best to secure one's rights in this life, and yet not infringe on the rights of one's neighbors, is always a difficult problem, but of the two men Truman came the nearest a solution.

DIPHTHERIA SPREAD BY ADULTS.

DR. A. JACOBI, in an article published in the *New York Medical Journal*, September 27th, expresses his opinion that the cause of most cases of diphtheria is to be found not in defective sewerage and damp walls, but in contagion from some individual sick with the disease, and expresses the opinion that many of the sore throats which do not confine their owners within doors or interfere with their business are, in point of fact, diphtheria, and capable of reproducing themselves in other individuals. While a tonsillar diphtheria is attended with scarcely any danger, the same disease in the larynx destroys a child by suffocation, and in the nasal passages is fatal by sepsis. No matter how slight a case is at first it may extend to nose or larynx, and in another person it may generate the most malignant form of the disease. It does not find lodgment in every person exposed to it any more than measles or

scarlatina. While a cannon ball, however, may miss, a pistol bullet may carry destruction.

"Such a bullet," says Dr. Jacobi, "is many a case of the so-called follicular amygdalitis (tonsillitis). There *is* such an affection as deserves the name. It implies a catarrhal or suppurative condition of a tonsillar crypt or several of them. It may be obstinate and extend over years, giving rise to constant returns of the secretion or to concretions. In the acute stage, even in the chronic, it will permit of the introduction of a probe into the duct to a depth of from one to two centimetres. The *color* of the secretion is often that of a membrane, not its nature, nor consistence, nor location (still it may become diphtheritic even inside the duct), and in that condition it is not diphtheria. But the large majority of cases which are commonly called follicular tonsillitis do not belong to this annoying but innocent class; *most of them are diphtheria.* Not everything not fatal need be called by a different name. What to-day looks like a point or four or five points covering the outlets of ducts may to-morrow be a confluent membrane. Just as well you might withhold the name of variola from a case of small-pox so long as it was not confluent or did not destroy life. You have a family sick with affections of the throat and nose; a child is dying of laryngeal croup; another of nasal diphtheria, glandular swelling, and sepsis; others have severe pharyngeal affections; others but slight tonsillar tufts, which may or may not coalesce and extend into membrane. Is the first one 'croup?' are the others 'diphtheria?' is the last one 'follicular amygdalitis?' Or the first case in a family was just such a one as was denominated tonsillar folliculitis by the family physician, and no preventive measures were taken to protect the rest of the little flock. From that moment it was that extermination began in that family. We have all seen it; we ought to heed it all."

Some of the mild cases of diphtheria, according to this writer, are most prolific of danger, because they are apt to assume a chronic course without losing their contagious nature. Instances are referred to where they have continued six or even nine months. While not depreciating the importance of domestic sanitation, Dr. Jacobi lays strong emphasis on the importance of examining the nares and throats of all attendants. He says that a family with children ought to insist upon the occasional inspection of the throats of their help. Servants with chronic pharyngeal catarrh must not be hired. A seamstress, coming for an occasional day's work, ought to have her throat inspected; cooks and nurses must be looked after, the more carefully the less such people are inclined to give way to their pains or ailments or throw up their places. A sick nurse introduced into a family must be examined; she will go from one place to another and carry pharyngeal and puerperal diphtheria. Thus if there be any class of persons who are the constant transmitters of diphtheria, and require attention and caution, it is nurses and cooks, in fact all domestic help; so do sick-nurses, teachers, hair-dressers and barbers, shop-keepers, restaurant-keepers, and all those people who are in constant contact with all classes and ages. The physician enjoys a certain degree of both active and passive immunity, but it depends on the number and duration of his exposures whether he becomes more or less both endangered and dangerous. *There is as much diphtheria out of bed as in bed; nearly as much out of doors as indoors.* Many a mild case is walking the streets for weeks without caring or thinking that some of his victims have been wept over before he was quite well himself.

The main points in the paper are thus condensed:—

"There is, probably, no spontaneous origin of diphtheria any more than there is a spontaneous origin of cholera or scarlatina.

"Diphtheria is contagious. Severe forms may beget severe or mild forms. Mild cases may beget mild or severe cases.

"What has been called follicular tonsillitis is *mostly* diphtheria. It is seldom dangerous to the patient, as the tonsils have but very little lymph communication with the rest of the body. But it is contagious.

"This form is frequent in the adult, in whom it loses nothing, however, of its contagiousness.

"Diphtheria in the adult proves dangerous to the community mostly because it does not restrain the patient from communicating the disease.

"It is apt to last long: firstly, because most cases occur on a surface covered with pavement epithelium (tonsils), secondly, because of the constant exposure and neglect on the part of the patient. Even without it diphtheria may last weeks and more; with it it is subject to sudden relapses. As long as it lasts it is contagious.

"As diphtheria is but a mild affection in many adults, who disregard it, and frequently do not care to mention its existence, pain in swallowing and moderate malaise being the only symptoms, the question of transmission by means of clothing, etc., on the part of third persons is capable of becoming more difficult to answer than it ever was. Many a case which has been believed to be thus carried is, probably, one of direct contagion from a patient to a second person, from this second to a third."

MENTAL ALIENATION IN YOUNG CHILDREN.

AN interesting résumé is given in the *Medical Times and Gazette*, September 6th, of a paper by Prof. Max Leidesdorf, read at the Vienna Medical Society.[1] At the beginning of the present century Carus entirely denied the existence of psychical disturbances in children, and it is only of late years, by means of the works of Brière, Conolly, and Maudsley and their successors, that the subject has been placed in its proper position. The writer himself has for some years past paid much attention to it in consequence of his having so often found that a proper appreciation of certain cases and certain forms of insanity in the adult can only be obtained by investigations carried back into early childhood. But if it is now certain that psychical disturbance may occur even before the fourth year of age, yet its relative frequency cannot well be determined, the statistics of lunatic asylums simply showing that admissions take place only rarely prior to the eighteenth year of age. By the census of Prussia for 1880 it was shown that there were 66,345 insane, or one to 411 adult inhabitants, while there was but one insane child to 1400 children. These statistical returns do not give even an approximative statement of the prevalence of the affection in children; but if we abstract cases of idiocy with or without epilepsy, dependent upon anomalies in the development of the brain, it must be confessed that insanity as it occurs in the adult is rare in childhood. But separate elements

[1] Wiener Medicinische Wochenschrift, June 28th and July 5th.

of such a condition of a rudimentary and transitory nature are frequently met with in the form of shortly lasting attacks of depression or excitement, alarm, and hallucinations. Professor Leidesdorf has often met with, in children not more than five years of age, transitory but frequently recurring conditions of depression, the causes being generally hereditary predisposition, loss of blood (for example, in pertussis), or preceding severe diseases, such as typhus, measles, scarlatina, etc. He refers to the case of a girl five years of age, who, although damaged hereditarily, was, as regards her intellect, in quite a normal and satisfactory condition, and yet was frequently seized on going to bed with attacks of groundless alarm, which lasted an hour or so, but leaving her in a normal condition. Sometimes, too, a hypochondriacal disposition is observed in children four or five years old, and this is especially the case when parents pay an exaggerated attention to their children's health, magnifying every trifling ailment into a serious disease, and managing by their excessive care to transfer their own anxiety to those who are the objects of it. On other occasions it is the witnessing severe illness, or the death of relatives, which saddens the child; and Professor Steiner refers to the case of a boy eight years of age, who, having seen a sister die of phthisis, from that time was the victim of the extremest fear of becoming a similar sacrifice. On the other hand, Professor Leidesdorf has met with examples in boys from six to eight years of age of great or even maniacal excitement with destructive impulse, which, however, lasted only for some hours. In one case the maniacal attack came on at the same hour every evening, but after some months the disposition entirely disappeared. A more frequent form of transitory psychical disturbance is hallucination of a disagreeable or terrifying nature, a typical form of which is well known to children's doctors under the name of *Pavor nocturnus*. Children from three to eight years of age, in a perfectly normal condition, after some hours' sleep are suddenly awakened, a prey to the greatest anguish, with pallid face and fixed look. The entire body is bathed in sweat, they utter loud screams, do not recognize those who surround them, and are the victims of hallucinations, which sometimes take the forms of dogs or serpents threatening them. These attacks sometimes come on at the same hour. At the end of an hour or less they fall asleep again, and on awakening are quite unaware of the occurrences of the night. Another type of transitory psychical disturbance is constituted by natural somnambulism, a condition which presents a great similarity to certain disturbances of consciousness which are sometimes met with prior to, or after, fits of epilepsy. These attacks of somnambulism occur not only at night in the midst of sleep, but also in the daytime. Peter Frank relates a case of this somnambulism brought on in a little girl through the operation of sudden fear, and Professor Leidesdorf gives interesting particulars of another girl, seven or eight years old, who was liable several times a day to hypnotic attacks, during which she exhibited many actions remarkable for the regularity of their execution. At the end of some months these attacks entirely disappeared. Besides these transitory conditions other psychoses may be observed in children five or six years old, which persist with variable intensity during the rest of life. To these belong the *ideas of constraint* (*Zwangsvorstellungen*), which are psychical representations entirely independent of the will, and which those surrounding the child take for simple creations of the fancy. Dr. Leidesdorf's experience in this matter has been gathered in part from children seven or eight years old, and in part from adults, who suffering from these images traced them back to early childhood. These manifestations differ from delirious ideas, as, contrary to what happen with these last, their subjects are quite aware that they have to do with an abnormal condition. The patient tries to repel these ideas, but in the struggle between the will and the ideas it is the latter that is always victorious. Some adults have been tormented by this condition from their earliest childhood, and have found their studies and occupations greatly interfered with; so that this double mental exertion, a part of which consists in withstanding these images, may at last tire them out into alienation. Prolonged mental affection in the proper sense of the word, such as we meet with in the adult, is very rare in children under fourteen years of age, and on account of its rarity Professor Leidesdorf cites some cases from his own and others' practice, for which we have not space. The more grave forms of neuroses are frequently accompanied by psychical disturbances, which last as long as the neuroses themselves. This is observed in epilepsy, chorea, and infantile hysteria. Hysteria, accompanied by psychical disturbance, is met with in children from five to fourteen years of age; and, according to the author's observations, it is the gravest form of hysteria which usually attacks children. Another form of disturbed mental condition observed sometimes in young children is a disposition to simulation, a remarkable case of which is related, and another quoted from West. Professor Leidesdorf terminates his paper by some observations on moral insanity, which, in its rudimentary stages, is not unfrequently met with in children.

ARTIFICIAL PRODUCTION OF LUNG DISEASE BY INHALATION.

WARGUNIN has just published[1] the results of an investigation which he has carried out in the laboratory of Professor Rajewsky, with the view of testing the effects of inhalation of phthisical sputa as compared with other organic matters. The experiments were performed on dogs, which were confined in a wooden box, through a hole in which a spray was directed upon the animal occupying the box. The substances to be inhaled, which were thrown into the box with the vapor, were phthisical expectoration, fresh and disinfected, emphysematous sputum, Swiss cheese, and wheaten flour. Eleven experiments were performed with unaltered phthisical expectoration, each animal undergoing several inhalations (varying from three to twenty-seven), after which it was allowed to live for some months until it died or was killed. Two of the eleven dogs, however, are still alive, being kept for further observations. Careful examination was made of all the organs after death, and in every case pathological products were found in the lungs, which to the naked eye had a close resemblance to tubercular nodules. Three experiments were made with phthisical expectoration disinfected by means of carbolic acid. In only one of these were there any morbid appearances resembling those in the former experiments, but

[1] Archiv für Pathologische Anatomie und Physiologie und für klinische Medicin, 5th June, 1884; and Edinburgh Medical Journal, September, 1884.

the animals were not allowed to live so long, which may account for the difference in result. One dog inhaled the sputum of an emphysematous patient; four were experimented on with a spray of cheese emulsion; and two with a similar spray of wheaten flour. One of these dogs, unfortunately, was bitten by another suffering from rabies at the commencement of the experiment (which was conducted with cheese), and its death was too soon to allow of the progress of any disease reaching a recognizable stage. The other six, however, on post-mortem examination gave evidence of exactly the same pathological processes having taken place as those which followed the inhalation of the phthisical sputum. Wargunin concludes from this that the pulmonary disease resulting from these inhalations cannot be due to a specific poison, but simply to the mechanical and chemical influence of the substances in the spray. He examined every lung microscopically, and found that the morbid products were caused by lobular broncho-pneumonia, not by any tubercular process. The clinical features of the disease which the animals manifested had nothing in common with tuberculosis.

OVERPRESSURE IN SCHOOLS.

THE British press is considerably agitated over a recent report by Dr. Crichton Browne on the above subject, which was accompanied by a memorandum of Mr. Fitch presenting the opposite side of the question from the stand-point of the Education Department. An abstract of each paper is published in the *Medical Times* (September 20th). Dr. Browne alludes to evidence of overwork (1) in detention after school hours, (2) from home lessons, (3) the impression of the teachers, only three per cent. of whom denied the existence of overpressure.

(4.) *The condition of the children* would settle the question of overpressure in itself. In the elementary schools the backward children were the ones who suffered from the effects of overpressure, as one teacher had forcibly observed to him, "Not only do these dull children break down in health under our manipulations, but they grow more stupid, seeming to lose in general intelligence what they gain in mere technical knowledge of reading, writing, and arithmetic." Examinations, he pointed out, were in this direction producing a rich crop in the future of nervousness. Backward children he divided into three classes, the dull, the starved, and the delicate. *Dullness* shaded off gradually into imbecility, a condition which might supervene at any point in the mental evolution. The *starved* constituted a more important section of the backward children. A not inconsiderable number of children were found to have come to school without any breakfast at all, besides a much larger number who were quite insufficiently fed. Then there were the *delicate* children, laboring from a great variety of ailments, but all were expected to get through the same amount of work and make the same progress as those who were healthy.

Overpressure had its origin in great measure in the *examination* system, and this arose from the system of *payment by results*, results proximate and partial, not the real final results, which could not be known under many years. When asked as to the effects of overpressure, the steady increase in insanity might be pointed out as an evidence of high pressure, though at present sufficient time had not yet elapsed to demonstrate its relation to education. The great increase in suicide, too, was instanced as coinciding in time with the modern extension of education, and as being most prevalent in regions where education was most widely diffused. But it was in other diseases of the brain and nervous system that the evils of overpressure were more clearly manifested, hydrocephalus and cephalitis being instanced as diseases which had become relatively more common at the school age during the last twenty years. Diabetes mellitus was specially singled out as an instance of the greater tendency to diseases of the nervous system in modern days.

The next step was to ascertain if any connecting links between these grave disorders of the nervous system and educational overpressure existed, and for this purpose he had inquired into the history of *headache* amongst some of the children. The result of this investigation was that 46.1 per cent. of the children professed to suffer from them habitually. These results were obtained after considerable cross-examination in every case where there seemed any reason to doubt the answer of the child. It was further found that in a considerable majority of cases the headache occurred in the afternoon, but that in the higher standards evening headache predominated, whilst the morning headache occurred, as might have been anticipated, amongst the half-starved. The headache was frontal in a very large proportion of the cases. Next the question of *sleeplessness* was inquired into, a subject beset with many difficulties, as various causes might intervene to produce sleeplessness besides school troubles, but *somnambulism* and *somniloquency* could be more easily proved to exist, and were found to exist in considerable proportion, and to be more or less directly associated with the school work. Of *chorea*, contrary to expectation, he met with no examples, though choreiform movements were occasionally seen.

A brief allusion was made to the relation of *neuralgia* and allied disorders and *shortsightedness* to education.

AN OYSTER MISTAKEN FOR A MALIGNANT GROWTH.

DR. THEOBALD relates the following incident at one of the Baltimore medical societies, according to the *Archives of Ophthalmology*. A patient having suffered from some obscure symptoms sought medical advice for the relief of her sufferings. A suspicious-looking mass was discovered blocking up the posterior nares. This was removed without difficulty, having, apparently, sloughed off from its former attachments. The supposed neoplasm being regarded as probably of a malignant character, it was deemed of the first importance that its histological structure should be made out. A portion of the tissue was teased out and submitted to a microscopical examination. This completed, the growth was exhibited to the Society in question, its histological characteristics were duly set forth, and the clinical facts of the case related. An animated discussion followed, and more than one hypothesis was advanced to account for the unusual features which the case presented. While this was in progress an inquisitive individual, with microscopical proclivities, inspected the tumor with more care than had previously been

thought requisite. The debate was suddenly cut short by the announcement that the suspicious neoplasm was, after all, but a half-digested oyster, a harmless specimen of our should-be familiar bivalve, which, probably, during a previous spell of vomiting, had become lodged at the point where it was discovered.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 27, 1884.

Deaths reported 2747 (no reports from Buffalo, Pittsburg and Milwaukee): under five years of age, 1201; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 782, diarrhœal diseases 403, consumption 364, lung diseases 175, diphtheria and croup 144, typhoid fever 82, malarial fevers 52, whooping-cough 37, scarlet fever 27, cerebro-spinal meningitis 16, puerperal fever eight, measles seven, erysipelas five, small pox one. From *malarial fevers*, New Orleans 13, St. Louis 12, Baltimore nine, New York seven, Brooklyn four, Nashville three, Charleston two, Chicago and Springfield one each. From *whooping-cough*, New York 11, Brooklyn six, Boston five, Chicago and District of Columbia three each, Providence two, Baltimore, Haverhill, and Lexington one each. From *scarlet fever*, St. Louis four, Chicago, Boston, and New York three each, Philadelphia, District of Columbia, Providence, and Lawrence two each, Brooklyn, New Orleans, Lowell, Lynn, Woburn, and Andover one each. From *cerebro-spinal meningitis*, New York five, Philadelphia three, Chicago, Baltimore, New Haven, Taunton, Newton, Fitchburg, West Brookfield, and Westborough one each. From *puerperal fever*, Boston five, Brooklyn two, New Orleans one. From *measles*, New York five, Cincinnati and District of Columbia one each. From *erysipelas* New York two, District of Columbia, Mansfield, and Sterling one each. From *small-pox*, Philadelphia one.

Cases reported in Boston: scarlet fever 30, typhoid fever 40, and diphtheria 16.

In 104 cities and towns of Massachusetts, with an estimated population of 1,179,491 (estimated population of the State 1,955,104), the total death-rate for the week was 23.01 agains 20.64 and 22.09 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending September 13th, the death-rate was 21.4. Deaths reported 3588: infants under one year of age 1179; deaths in London 1373: acute diseases of the respiratory organs (London) 170, diarrhœal diseases 531, whooping-cough 71, scarlet fever 65, measles 46, fever 45, diphtheria 31, small-pox (London nine, Liverpool two, Sheffield and Hull one each) 13. The death-rates ranged from 9.2 in Brighton to 35.4 in Blackburn; Birmingham 16.1; Bradford 19.9; Leeds 26.8; Leicester 31.0; Liverpool 24.8; London 17.8; Manchester 27.5; Nottingham 21.3; Plymouth 15.2; Sheffield 27.4; Sunderland 25.8. In Edinburgh 16.7; Glasgow 24.8; Dublin 29.4.

For the week ending September 13th, in the Swiss towns, there were 21 deaths from diarrhœal diseases, consumption 20, lung diseases 12, typhoid fever four, erysipelas two, puerperal fever one, small-pox one, scarlet fever one, diphtheria and croup one. The death-rates were, at Geneva 8.2; Zurich 13.8; Basle 14.7; Berne 17.8.

For the week ending September 10th, in Paris, there were 202 deaths from consumption, typhoid fever 41, diphtheria and croup 30, measles 26, whooping-cough nine, erysipelas four, puerperal fever three. The death-rate was 22.87.

The meteorological record for the week ending September 27th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM SEPTEMBER 20, 1884, TO OCTOBER 3, 1884.

HALL, JNO. D., captain and assistant surgeon. Assigned to duty at Fort Townsend, Wash. Ter., to relieve Surgeon R. S. Vickery. Surgeon Vickery, on being relieved, directed to report to commanding officer, Vancouver Barracks, Wash Ter., for duty. Paragraph 3, S. O. 140, headquarters Department of Columbia, September 15, 1884.

BIRMINGHAM, H. P., first lieutenant and assistant surgeon. Leave of absence extended twenty days. Paragraph 2, S. O. 116, headquarters Division of the Missouri, September 22, 1884.

BARROWS, C. C., first lieutenant and assistant surgeon. Granted one month's leave of absence, with permission to apply to the proper authority for an extension of one month. Paragraph 4, S. O. 86, headquarters Department of Arizona, September 13, 1884.

DIETZ, W. D., first lieutenant and assistant surgeon. Assigned to duty at Fort Selden, N. M. (post surgeon). Paragraph 4, S. O. 187, headquarters Division of Missouri, September 18, 1884.

MCCAW, W. D., first lieutenant and assistant surgeon. Assigned to duty as post surgeon, Fort Craig, N. M. Paragraph 5, S. O. 187, headquarters Division of Missouri, September 18, 1884.

BENTLEY, EDWIN, major and surgeon. Granted two months' leave of absence, with permission to apply for two months' extension, to take effect upon assignment to duty in Department of Texas of Surgeon F. L. Town. S. O. 121, headquarters Division of the Missouri, September 30, 1884.

BARTHOLF, JOHN H., captain and assistant surgeon. Assigned to duty at Fort Ringgold, Texas, as post surgeon. Paragraph 5, S. O. 129, headquarters Department of Texas, September 25, 1884.

WHITE, R. H., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Winfield Scott, Cal., relieving Assistant Surgeon A. S. Polhemus, who, upon being relieved, will report to commanding officer, Alcatraz Island, Cal., for duty. Paragraph 1, S. O. 113, headquarters Department of California, September 19, 1884.

TESSON, L. S., captain and assistant surgeon. Directed to report to commanding officer, Fort Stockton, Texas, for temporary duty. Paragraph 3, S. O. 127, headquarters Department of Texas, September 22, 1884.

GIBSON, R. J., first lieutenant and assistant surgeon. Assigned to duty as post surgeon, Fort Winfield Scott, Cal., relieving Assistant Surgeon A. S. Polhemus.

POLHEMUS, A. S., first lieutenant and assistant surgeon. Upon being relieved to report to commanding officer, Fort McDermit, Nev., for duty as post surgeon.

WHITE, R. H., captain and assistant surgeon. To report to commanding officer, Angel Island, Cal., as post surgeon, relieving Assistant Surgeon C. K. Winne.

WINNE, C. K., captain and assistant surgeon. Upon being relieved to report to commanding officer, Benicia Barracks, Cal., for duty as post surgeon, relieving Surgeon C. C. Byrne. Paragraph 1, S. O. 115, headquarters Department of California, September 23, 1884.

MADDOX, T. J. C., first lieutenant and assistant surgeon. Directed to report to commanding officer, post of San Antonio, Texas, for duty. Paragraph 5, S. O. 127, headquarters Department of Texas, September 22, 1884.

BARROWS, C. C., first lieutenant and assistant surgeon. Leave of absence extended one month. Paragraph 6, S. O. 97, headquarters Division of the Pacific, September 19, 1884.

EVERTS, EDWARD, first lieutenant and assistant surgeon. Granted leave of absence for one month, with permission to leave the limits of the Department. S. O. 145, headquarters Department of Colorado, September 24, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING OCTOBER 4, 1884.

STEWART, HENRY, surgeon. Granted leave of absence for one year, with permission to leave the United States. October 15, 1884.

EDGAR, JNO. M., passed assistant surgeon. Detached from the Nantucket and placed on waiting orders. September 29, 1884.

HARMON, G. E. H., passed assistant surgeon. To the Naval Academy. September 30, 1884.

BERTOLETTE, D. N., passed assistant surgeon. From the Naval Academy to the Dolphin. October 4, 1884.

ROGERS, BENJ. F., passed assistant surgeon. To the Naval Academy. September 30, 1884.

COOKE, GEO. H., surgeon. From the Naval Academy and placed on waiting orders. October 2, 1884.

WHITING, ROBERT, passed assistant surgeon. From the Naval Academy and placed on waiting orders. October 4, 1884.

AMERICAN PUBLIC HEALTH ASSOCIATION. 1884. TWELFTH ANNUAL MEETING, SAINT LOUIS, MO. — The American Public Health Association will convene at Saint Louis, Mo., Tuesday, October 14th, at ten o'clock, A. M., and continue four days. The meetings will be held in Liederkranz Hall, corner of 13th Street and Chouteau Ave. Papers have been promised for this meeting as follows: on I. Hygiene of the Habitations of the Poor. II. Hygiene of Occupations. III. School Hygiene. IV. Adulteration of Food. V. Water Pollution. VI. Disposal of Sewage by Irrigation or Chemical Action. VII. The Observable Effect upon the Public Health of Official Sanitary Supervision. VIII. The Work of Municipal and State Boards of Health. IX. On Disease Germs. X. Cremation as a Sanitary Measure in Times of Great Epidemics. XI. A Survey of the Present Sanitary Situation in Saint Louis

The headquarters of the Executive Committee will be at the Southern Hotel. The first meeting of the Committee will be held Monday, October 13th, at 2.30 P. M.

The conference of State Boards of Health will meet at Liederkranz Hall, Monday, October 13th, at 2.30 P. M.

After October 5th all communications to the Secretary should be sent to Southern Hotel, Saint Louis, Mo.

IRVING A. WATSON, *Secretary.*

Original Articles.

EXCEPTIONAL FATTY TUMORS.[1]

BY R. M. HODGES, M. D.

If an attempt were made to enumerate the mistakes of surgery the list would be a long one, especially if surgeons manifested as much alacrity to report their failures as they do to give an account of their successes. Such a catalogue of discomfitures, however exhaustive, would not prevent errors from happening, but it might exhibit the difficulties of surgical art and inculcate that prudent reserve in the expression of opinions, want of which is a fault often condemned, and the possession of which is a virtue greatly respected by the profession, if not by the public. It might also help to repress a prevalent intellectual propensity which permits preconceived opinions to subvert deliberation of judgment.

I propose to report, in brief terms, four cases of erroneous diagnosis which have left an impression on my mind, not on account of their seriousness, as in each instance the mistake was to the patient's advantage, but because they are striking illustrations of misconception, all of them having reference to an affection usually counted one of the simplest and easiest for surgical recognition.

Case I. A. M. C., female, aged five, well developed, and, except for some slight cerebral symptoms while teething, always perfectly healthy, is the subject of a tumor of the occiput, in the median line, over the tendons of the trapezii muscles. It was first noticed at the age of three months, and has gradually increased in size; ovoid in shape, two by three inches in its diameters, regular in outline, the superior border nearly reaches the occipital ridge and protuberance. The integument is natural and slides upon the growth, which is itself apparently movable upon the muscles beneath. It has the feel of a soft solid, and is translucent when examined through a hydrocele tube. It does not pulsate with the breathing or crying, nor has the patient suffered inconvenience from the tumor, or any apparent pain when it has been handled or bumped.

More than a year before my interview the mother was advised at the Massachusetts General Hospital that an operation had better not be performed. Subsequently she again received similar advice, with the added recommendation that a shield of gutta-percha should be worn; the opinion of those who saw it being that the tumor was a meningocele, having more or less direct communication with the serous membranes of the encephalon and spinal cord. Eventually, and with a full understanding of the danger, the parents decided that they would prefer to have an operation performed and take the chances of the child's death at present rather than suffer the tumor to remain.

After etherization a fine trocar was inserted into the tumor. No fluid came through the canula, not even blood. After consultation by the surgeons present it was thought advisable to determine the character of the growth by an incision. This being done a very beautiful specimen of fatty tumor was exposed and easily removed.[2]

This particular fatty tumor happened to present features which, as a rule, do not belong to that class of growths. A lipoma, congenital, situated in the median line of an exceptional locality, and translucent, offers an assemblage of phenomena which might justify the blunder of taking it for a meningocele, properly belonging in the point described, which is of necessity congenital, and offers nothing irregular in being translucent; but the sequel proved that not enough importance was attached to the absence of fluctuation, of pulsation, or to the movableness of the tumor. I am not aware that fatty tumors are often translucent, but the delicacy of color and fineness of texture which they frequently present (as in the case under consideration), coupled with the fact of their oil-cells being much larger than those of ordinary fat, suggest that the transmission of light through their structure may not be a rare phenomenon.

Case II. S. N., a thin and anæmic man, of indifferent health, aged fifty-eight, is the subject of a smooth and rounded tumor in the median line of the neck, between the hyoid bone and thyroid cartilage. It had slowly enlarged during the four or five years it had been observed, until it reached the size of a small egg, and became annoying from its prominence. Painless, not adherent to the skin, fixed to the deep tissues, and fluctuating, it was unhesitatingly diagnosticated as a cystic tumor by more than one surgeon, and its removal recommended. By medical advice the tumor was unavailingly painted with tincture of iodine for a period of several months. Discouraged by the failure of this application, Mr. N. consented to an operation. As the growth was fixed and not small, it seemed that the dissection which would be required might present some difficulty, or at least open the way for subsequent burrowing of pus. The operation was consequently performed with careful antiseptic precautions; but the tumor was found to be an ordinary lipoma, easily removed. Rapid healing and an insignificant cicatrix followed.

Fatty tumors are always surrounded by a capsule of connective tissue which in its totality constitutes a more or less complete cystic envelope. The defined outline thus given to the one in question and its fluctuation contributed to the deception by which the diagnosis was entrapped. Its locality, moreover, is one particularly affected by cystic growths, and unusual for lipomata. Although fatty tumors may be found in any part of the body, in the bones, viscera, and beneath muscles, they are rare in certain places, and generally occur only in superficial positions abundantly provided with fat.

Case III. H. R. S., aged twenty-three, has a somewhat flattened, round, subcutaneous tumor over the horizontal ramus of the jaw, alleged to be of but a few months' duration. It is about one inch in diameter, defined in outline, slightly movable, not tender, fluctuating. The skin is little, if at all, adherent to the tumor. In short, the appearances presented are those of an indolent abscess. On looking for an explanation it was found that the lower canine tooth of that side was dead and contained a large gold filling; but it was not, nor had been recently, tender or inflamed. To avoid a scar, and in the hope of emptying the abscess internally, I advised extraction of the tooth, even though subsequently an external incision should be required for drainage of the purulent cavity, believing if it were allowed to remain that a fistulous opening and disfiguring adhesions would be sure to follow. The

[1] Read before the Surgical Section of the Suffolk District Medical Society, June 17, 1884.

[2] M. G. H. Records, vol. lxxvi., p. 206.

tooth was pulled, and some time after the patient returned with the tumor unchanged. An incision, which was then made, proved the supposed abscess to be a fatty tumor, easily squeezed out from its bed through a small opening in the skin.

Blinded by the exceptional situation and the patient's statement of its duration, which in all probability had been for years rather than months, the mistake was made of attributing this tumor to an irritation which did not exist. Hasty generalization from a first and strong impression led to an erroneous diagnosis, which closer attention might have averted. The case is also an instance, not infrequent, of the fact that a well-developed tumor may pass unnoticed by its possessor for a period of time hardly conceivable.

Fluctuation is a phenomenon often believed to be present because the surgeon thinks it should be. The impression is in the brain and not at the fingers' tips. Many an old-fashioned surgeon, in the eyes of his students "great on deep-seated fluctuation," owed this reputation to his experience rather than to his *tactus eruditus*. Genuine fluctuation is, however, an acknowledged attribute of many fatty tumors, and is due to the presence of large numbers of oil-globules and a small amount of connective tissue. At the Academie de Médecine Lisfranc once placed on the table a number of tumors covered by their integuments, and submitted them to examination. The surgeons present all agreed that there was fluctuation, and yet the tumors were in each instance fatty.[1] Therefore, neither in the case just read nor in the preceding was the existence of fluctuation any justification of the errors which were made.

CASE IV. C. H., aged sixty-four, an educated man, of exceptional capacity, in perfect general health, two weeks before being seen fell on the ice, severely hurting himself about the hip. A week afterwards he first noticed a painless tumor about four inches in diameter, filling the space of Scarpa's triangle, defined, lobulated on the surface, and at its periphery slightly, if at all, movable, firm, and non-fluctuating in substance. The integument was adherent and traversed by conspicuous veins. There were no enlarged glands in its vicinity, or above Poupart's ligament. Although the patient had noticed this tumor but for one week, and only two weeks had elapsed since his fall, it plainly was not of an inflammatory character, and, from the appearances presented, it was equally obvious that the growth must have been of longer duration than supposed, and bore no relation to the accident which had befallen him.

Notwithstanding the absence of local or previous symptoms, and the patient's conviction that there had been no swelling in the region before his fall, the serious character of the growth could not be doubted. I expressed the opinion that it was a sarcoma, and gave a discouraging answer to inquiries in regard to the expediency of an operation for its removal.

During the succeeding twelve months the tumor underwent little or no change, and was examined by several surgeons, all of whom coincided in the diagnosis which had been given. C. H. finally entered the Massachusetts General Hospital, and, after much deliberation, an attempt to remove the tumor was decided upon. This was undertaken with every precaution to insure the success of what promised to be a long and dangerous operation. On exposing the growth it proved to be a lipoma, traversed by numerous fibrous bands, and closely adherent to all contiguous parts. It was evidently an old inhabitant of the situation it occupied, and a still more curious illustration than the preceding one of the fact that a tumor will long remain undetected by its possessor, even when in a palpable location.

In this case the patient's self-deception contributed to the error of diagnosis, but the tumor, from intrinsic evidence, was so clearly of long standing that his statements to the contrary should have had no influence. Its actual age had led to changes which effaced some of the usual features of a lipoma, and its situation, as in the cases of supposed meningocele and thyro-hyoid cyst previously related, was deceptive, in that it is usually the habitat of a graver class of growths. The alleged association with an injury is one commonly made or sought for in all cases of tumors, but the great source of error was an assumed rapid development, and, in the absence of inflammatory phenomena, this could be occasioned only by a malignant growth. I doubt if, under the circumstances, it was possible to have formed a correct conception of the nature of this tumor. Any one diagnosticating a lipoma would have made but a lucky guess.

I will briefly describe five other fatty tumors of which I have a few memoranda, and which were not diagnosticated before operation, their character remaining in doubt until after removal, owing to the situation in which they were developed.

A seaman, aged twenty-three, seven years before admission to the Massachusetts General Hospital, first noticed a tumor, the size of a pea, in the middle of his right palm. This grew slowly until it was one and a half inches in diameter, ovoid in shape, soft, fluctuating, painless, immovable, apparently subcutaneous, not interfering with the motion of the fingers, and only troubling him in his occupation as a fisherman by the pressure of his fish-line. An incision being made, the growth was easily enucleated by the fingers, and found to be a fatty tumor composed of many compressed lobules. No arteries were tied.

A laborer, aged forty, presented himself at the Massachusetts General Hospital with a small tumor between the index finger and thumb, which, when first detected, two years previously, he attributed to the pressure of a wood-saw. At first painless, it subsequently became painful on pressure, or when the hand hung down, the pain streaming up the arm as if a nerve were involved. The tumor was most prominent on the dorsum of the hand, and at the time of operation was as large as an egg, ill-defined, partly concealed under the palmar fascia, soft, fluctuating. The integument covering it was natural in color, and in no way involved. Its removal, requiring an incision four inches long, was accomplished chiefly by the fingers. The first dorsal inter-osseous muscle was divided to give access to the tumor, which was an ordinary lipoma. No vessels were tied.

From a position similar to that in the preceding case, between the index finger and thumb of a man aged seventy-three, a fatty tumor, the size of a potato, and of thirty-five years' growth, was removed, or rather torn out, at the Massachusetts General Hospital, through an incision in the palm. One artery required a ligature.

A female, aged fifty-five, twenty-two years before operation, observed a tumor as large as a pea on the right side of her forehead, within the hair. During

[1] Compend. de Chir., vol. i., p. 605.

the last six years it had grown to the size of an apple. It was immovable, and not sensitive or uncomfortable, except from its position and dimensions. Its removal was easy, and unattended by bleeding. It proved to be an ordinary fatty tumor.

A man, aged fifty-six, twelve years before admission to the Massachusetts General Hospital, discovered a "bunch" in the lower part of his right scrotum, hard, unconnected with the testicle. Seven years afterwards there appeared a second "bunch," larger than the first, and situated above it. Both were movable, and not tender. Within fifteen months these had grown rapidly, until the scrotum reached the dimensions of an infant's head. The enlargement was confined wholly to the right side, and appeared to be made up of several distinct tumors; one, at the lower part, being equal to an orange in size, while another, above it, was still larger, but flattened in shape. They were just beneath the integuments, and the interval between them fluctuated, as if occupied by a fluid. Both testicles and cords were natural. A small hernia existed on the side of the tumors, for which the patient wore a truss. An operation removed a multilobular fatty tumor. One or two veins were tied, but no arteries. The recovery was interfered with by a secondary hæmorrhage, however, of considerable amount.

In this latter group of cases the record of apparent fluctuation, noted at the time of examination, presents itself again as a conspicuous peculiarity of fatty tumors, and justifies the comments already made.

Another feature, which may be remarked upon, is the statement, three times repeated, that the tumor was torn out, or enucleated, by the fingers; a procedure not unsurgical or exceptional, but which illustrates the loosely encapsuled character of these growths, and, while familiar as a method often adopted in their usually rapid removal, it is one not commonly alluded to by surgical authors.

The infrequency with which vessels call for ligature after the removal of lipomata prompts me to speak of the exudation of serum which usually takes place, to a large amount, in the space vacated by the tumor. This formerly occasioned trouble by distending the cavity, decomposing, and finally becoming purulent, and, at the expiration of a few days, obliging an opening to be made in the line of an incision which has usually united by first intention. Such a sequel of the operation is now happily prevented by aseptic dressings and the invariable practice of inserting a drainage tube in the wound.

ANTISEPTIC HERNIOTOMY WITH SUTURE OF THE PERITONEUM.[1]

BY A. T. CABOT, M. D.

THE dangers of herniotomy have been greatly reduced, no doubt, by the introduction of modern antiseptic methods, but the correct appreciation of the properties of the peritoneum learned in abdominal surgery has done, perhaps, even more to limit the death-rate of this operation.

Formerly the surgeon, in closing the wound after the reduction of a strangulated loop of intestine, brought the edges of the skin neatly together, and drained the cavity of the sac more or less perfectly with a seton or tube. If a wound treated in this manner suppurated the pus found easy access to the abdominal cavity, and fatal peritonitis was the frequent result, a result vastly more common at that time in umbilical than in inguinal hernia, as in the former the pus, naturally, gravitated directly into the abdomen, while in the latter it had to find its way up the inguinal canal, the walls of which, being held in apposition by a compressing pad, often closed by adhesive inflammation before suppuration commenced.

We now know that if the peritoneal surfaces at the ring are brought snugly together with deep stitches they quickly cohere and shut the wound off completely from the cavity of the abdomen. This cohesion of the peritoneum is very firm at the end of twelve hours, as has been frequently confirmed by autopsy after ovariotomy, and as suppuration does not commence inside of twelve hours the peritoneum is completely closed before any collection of pus and penetration of it into the abdomen can occur. After the peritoneum has thus united the outer wound may gape open, may suppurate, may even take on an unhealthy, sloughy character without implicating the abdominal cavity. Another advantage to be gained by the careful approximation of the peritoneal surfaces about the hernial ring is the very great probability of obtaining a radical cure by so doing. In order to place the stitches as advantageously as possible with this end in view the operator should draw down the hernial sac as far as possible, and place his stitches well within the ring, as in this way he brings the peritoneal side of the wound smoothly together, and avoids leaving a pocket in which a new hernial protrusion may commence. This remark applies especially to inguinal hernia, and the following case will serve as an illustration of this method of treatment:—

James H., thirty-eight years of age, entered the Massachusetts General Hospital July 9, 1882, with the following history:—

The patient has had a right inguinal hernia for many years, and has worn a truss for it, but although the truss is a good one the hernia often escapes from it. Five or six hours before entrance to the hospital he was seized with sudden pain while riding in his cart, and found that an unusually large protrusion had taken place. A physician whom he called upon tried taxis for two hours without effect.

The hernia at the time of entrance was about the size of a large fist, very hard, red, and tender. I saw the patient soon after his arrival in the hospital, and after trying taxis moderately under ether I proceeded to operation.

The sac contained about a foot and a half of deeply congested intestine. After incising the constricting portion of the ring there was still great difficulty in reducing the prolapsed intestine. This was finally accomplished by raising the pelvis and tucking it slowly in, beginning with the portion that came out last. The pillars of the ring were tightly sewn together with chromicized catgut, and the outer part of the wound brought together with silk.

The recovery after this operation was uninterrupted.

I have seen this man within the past six weeks (twenty months after the operation), and the hernia has never been down since. He still wears a truss as a precaution, but the impulse upon cough over the

[1] Read before the Surgical Section of the Suffolk District Medical Society, March 7, 1884.

ring on the affected side is little, if at all, more marked than on the well side.

In femoral hernia the proximity of the great vessels renders the placing of deep stitches a matter of considerable danger, while in umbilical hernia the stitches are readily placed through the peritoneum on each side of the opening, just as in an ovariotomy wound.

A large redundant sac often interferes seriously with a nice approximation of the wound, and should be freely cut away. This is especially important in umbilical hernia, as in this form the sac is composed largely of the cicatricial tissue of the expanded umbilical scar, which heals badly, and which if left would form a considerable cavity very liable to suppurate. If, on the other hand, the sac be carefully trimmed off the sides of the umbilical ring and of the opening through the skin can be brought together as one linear wound, which heals readily.

There are few procedures concerning which surgical opinion has changed so entirely in the past twenty years as it has in regard to the operation of kelotomy for strangulated umbilical hernia.

No longer ago than 1861 Huguier stated his opinion before the Société de Chirurgie of Paris that "in strangulated umbilical hernia, whether intestinal or omento-intestinal, it is, perhaps, better to abandon the hernia to the efforts of nature, watching and combating complications, than to attempt a regular operation of kelotomy." This opinion he sustained by statistics, and in spite of opposition by Richet and other contemporaneous surgeons the ideas of Huguier prevailed.

In 1865 Gosselin urged that the operation was by no means as grave a one as was currently supposed, and that if it was done within forty-eight hours after strangulation occurred the prognosis was no worse than in other hernias, but this view did not become a general one.

In 1875 Desprès reported a successful case after operation, and Verneuil spoke in favor of non-interference, while Perrin and Le Dentu supported the operation.

In 1881 Terrier again brought the matter under discussion in the Société de Chirurgie, reporting three cases of operation with two recoveries. Polaillon also reported three cases with two recoveries. And Verneuil admitted that in view of the advance in surgical treatment he could no longer sustain the opinion he had held in 1875, but must regard the operation as justified in these cases, with the reservation that it should only be used in small hernias, which opinion was supported by Desprès, while the other surgeons taking part in the discussion inclined to the belief that even large hernias should be operated upon if the symptoms were menacing.

This rapid change of practice among French surgeons serves as an illustration of the reversal of opinion that was taking place throughout the surgical world.

Among the Germans, in 1869 Uhde published a series of 122 cases, which underwent operation with a mortality of 46.7 per cent. And in 1879 Geissel considered that Huguier's advice to let these cases alone should be disregarded.

The English journals begin after 1875 to contain not infrequent reports of successful operations, and in 1883 Lawson Tait states that he has operated upon eleven cases, all of which recovered, and that he does not remember a case of death after the operation in his hands.

My own experience with strangulated umbilical hernia has included three cases. The first I saw some years ago in consultation with Dr. W. Symington Brown, of Stoneham. The patient was a large, stout woman. The protrusion was as large, I should say, as an infant's head. The integument covering it was red and shining in places, and the sac was evidently much inflamed, with the contained intestine, probably, held by many adhesions. Abdominal pain and vomiting were present, either from strangulation or peritonitis. Aspiration was resorted to with the hope of relieving tension, but without success. Expectant treatment was followed, and the patient died.

The second case, a hospital patient, was seen after peritonitis had set in. The protrusion was a small one, about half the size of the fist, and was very tense and painful. Poultices were applied, and the expectant method of Huguier was followed, but the patient died. There was no autopsy. This patient also was a middle-aged, fat, and flabby woman.

The third case I will report more at length: Mary C., a fat woman, forty-seven years of age, entered the Massachusetts General Hospital January 13, 1884, with the following history: She has had a protrusion at the umbilicus for the past nine years, and this, although reducible, has been down most of the time. On January 10th (three days ago) the hernia became very tense, and she suffered somewhat from pain. The morning of the 13th she began to vomit and to have intense pain through the abdomen. I saw her at about eight P. M. in the accident room of the hospital. The patient was cool and perspiring, but had a fair pulse. The protrusion situated at the umbilicus was about the size of an orange, tense, red, and glossy, and very tender when touched. I was fortunate in obtaining the counsel of Dr. Bigelow and Dr. Hodges, who advised an exploratory incision with the intention of returning the intestine if of good color, but if it were gangrenous of leaving it without interfering with the strangulating ring.

I operated by an incision over the lower part of the sac and the adjoining skin. No distinct layers could be made out in the wall of the sac. The interior was quickly reached, and the contents were found to be a coil of the intestine nine or ten inches in length, and a considerable mass of omentum, which was adherent to the inside of the sac. The ring was incised at its lower edge in the linea alba, and the intestine, which was much congested, but not gangrenous, was easily returned.

The omentum was so extensively attached to the sac that it could not be easily separated; it was therefore tied and cut off with the Paquelin cautery. The sac was then cut away and the wound brought together with silk sutures, which included the peritoneum.

The operation was done under carbolic spray with all antiseptic precautions, and a gauze dressing covered with cotton batting, and held in place with a swathe, was applied. The patient bore the operation well. On the following day she had considerable pain in the right side of the abdomen on a level with the umbilicus, for which she took morphine in moderate doses. She passed wind from the bowels on the third day after the operation, and on the fifth day her bowels moved naturally. She was now free from pain and seemed well in every respect. The wound was dressed for the first time nine days after the operation, and was found to have united by first intention. It gave no subsequent

trouble, remaining firmly healed with apparently entire obliteration of the ring. On the ninth day she took a little solid food for the first time, having been kept upon liquid nourishment until then. This change in diet was followed by considerable pain in the abdomen, referred to the neighborhood of the umbilicus, and colicky in character. A little hardness and fullness was to be felt just to the right of and above the umbilicus. This region was tender to pressure. The bowels being rather constipated several small doses of castor oil were given, with the effect of producing a free, easy movement and relieving the pain.

Several times during her subsequent stay in the hospital the same course of events was noticed, namely, that when the bowels were constipated she suffered from cramps with occasional vomiting, which symptoms were relieved by a mild cathartic.

It seemed from these symptoms that the bowels were somewhat obstructed, probably owing to adhesions contracted by the loop of intestine that had been returned while somewhat inflamed, and had set up a local peritonitis in its neighborhood. The seat of this mischief was thought to be in the colon, to the right of the umbilicus, where the slight hardness and tenderness existed.

Under the use of poultices and laxatives these unpleasant symptoms disappeared, the tenderness and hardness vanished, and she was able to be up and to partake of ordinary food. Finally towards the middle of March she was walking about nearly all day without discomfort, and being anxious to get home to South Boston permission was given her to go home in a carriage.

She wished to leave March 17th. Upon that day, before the arrival of the carriage, the idea occurred to her to surprise her sister who lived at a considerable distance. With this intention she left the hospital on foot. I have since learned that contrary to all advice she walked more than a mile, and after great fatigue reached home in a very poor plight, and died about a fortnight or three weeks later. From Dr. P. F. Gavin, of South Boston, who was called to see her after she reached her friends, and who attended her until her death, I learn that the symptoms when he saw her were pain and tenderness about the umbilicus, tympanites, and vomiting. The bowels were constipated, but moved slightly after enemata. These symptoms increased in severity up to the time of her death. The treatment was with opiates and without laxatives. No autopsy was obtained. The death of this patient, though probably an indirect consequence of the strangulation, cannot be set down to the operation, which was thoroughly successful, and restored her to a state of health which nothing but folly as great as her own could have destroyed.

The wound left by an operation done in this manner for umbilical hernia differs in no essential particular from the simple incised wound of an ovariotomy, which almost invariably heals readily. If, therefore, inflammation has not already begun in or around the sac, it seems reasonable to expect a very fair measure of success from antiseptic umbilical herniotomy, and the experience of modern operations shows that even when inflammation is present a carefully aseptic operation will give the patient many more than even chances of recovery.

As inflammation when started introduces the greatest element of danger in these cases, it certainly seems well to adopt the rule given by Gosselin, that the operation should be done as soon as possible after strangulation has occurred.

FUNCTIONAL AFFECTIONS OF JOINTS.

BY E. H. BRADFORD, M. D.

IN contrast to cases with definite organic changes and the resulting impairment of usefulness, a class of joint affections presenting impairment of function without evidence of organic change is of interest.

The term "hysterical" is commonly used to describe this class, a term which, meaning nothing, frequently misleads, implying as it does a group of concomitant symptoms not always present. The compound word "neuro-mimesis" has also been employed, but suggests feigning, which is frequently not the case. "Functional," used in this way, signifies simply what is known to exist, namely, an impairment of the usefulness of the member without any hypothesis as yet problematical as to the cause of the disorders.

A few cases will serve as illustrations.

CASE I. A well-nourished girl, seven years of age, entered the Children's Hospital for a right-angled contraction at the left hip-joint, which was said to have persisted for over a year, and to have followed what had been termed trouble at the hip. The child was, apparently, of a nervous, excitable disposition, but complained of no pain. The contraction at the hip-joint was persistent, and the limb was not seen to assume at any time a normal position. The patient walked about with crutches. The distortion was so marked and characteristic that I, on a casual examination, considered it an ordinary case of the contraction following hip disease. Dr. Langmaid, however, under whose care the case fell, recognized the nature of the affection, etherized the patient, and easily, under the anæsthesia, restored the limb to its normal position, and fixed the leg in a plaster-of-Paris bandage. The patient fell under my care, and it was found that, on removal of the bandage, the leg resumed its vicious position. A lighter stiff bandage was applied and worn for a month, but the result was the same. On removing this a light steel support was then applied, fastened to the shoe, reaching from the heel to the upper part of the thigh, and by a strap, which passed over the knee, prevented flexion at the knee and contraction at the hip. The child walked about readily with this without crutches, and at night wore a ham splint. Demonstrating the effect of mental influence in causing the distortion, it was found that while the splint was worn no contraction took place even when the strap (which alone prevented the contraction) was taken away; if, however, the splint itself were taken off the limb recontraction instantly occurred. At the end of two months the patient left the hospital, but was brought back as an out-patient. At the end of six months, however, she was reported to have developed a similar distortion in one of her other limbs.[1]

CASE II. A girl of healthy appearance, well nourished, nine years of age, fell, striking upon her knee. She was placed in bed, and kept in bed for two months, the family dreading hip disease, an acquaintance having

[1] For a somewhat analogous case vide Jahrbuch. f. Kinderheilkunde, Band xv., 1 Heft. See also Riegel, Zeitschr. f. klin. Med., 1883, Band vi., Heft 5.

suffered from hip disease, a result of a slight fall. When the girl was allowed to walk about she complained of pain in her right hip, and limped when walking. This persisted for a month. In the meanwhile the child was allowed to go about but little.

On examination absolute freedom of motion was found at the hip-joint as compared with the normal side; no atrophy was present, and it was inferred that no disease of the joint existed. The patient was furnished with crutches, the shoe of the well side raised, and the patient allowed to walk about upon crutches, but directed to bear no weight upon the affected limb. The mother was directed to rub the limb well twice a day. In a short time, as no further evidence of joint trouble manifested itself, although the child continued to complain of slight pain in walking, the lift on the shoe was removed, and the child directed to walk without crutches, at first only a short time in the house, the length of time being gradually increased, and finally crutches were removed altogether. No trouble has followed up to the present time, thirteen months.

Case III. S., a school-mistress, twenty-six years of age, with a history of a severe attack of "spinal irritation" two years before, presented herself with the statement that she was suffering from "hip trouble." Her hip had felt "weak" for three months, and the patient thought she had strained it three weeks before, but had sustained no fall. The patient limped badly in walking, held the limb flexed at the thigh, did not put heel to the ground in walking, complained of pain in the hip and knee, chiefly at the hip. In a recumbent position the left thigh was held flexed, and on any motion or jar the patient complained of pain in hip and knee, also of great tenderness about the groin and hip. No atrophy of the thigh was present. The patient slept well, and was free from morning stiffness. Hip disease was excluded from the absence of atrophy, the extreme tenderness coupled with an ability to walk about with comparative freedom (although with a limp); further, the limp did not resemble the usual limp seen in hip disease, and although on passive motion of the hip extreme pain was complained of the patient moved the limb rather more freely than is usual in cases of hip disease in a stage of extreme tenderness. The patient was evidently of a nervous temperament, and had worked constantly in charge of a large public school, allowing herself but little or no rest.

The treatment consisted of absolute recumbency for a short period, followed by gradually increased motion. But little or no improvement in the patient's condition followed for a few weeks. At the end of six or eight weeks she was allowed to get up, and improved noticeably. The patient left home for a few weeks' stay at St. Margaret's Home, where the treatment consisted in giving a required task of motion, increasing each day, and a routine of occupation. In a fortnight the patient became able to walk about freely with crutch or cane, and without complaint of pain to go up and down stairs, and in two months was able to walk quite long distances. She has since resumed her position as school-teacher, and during the past year she has reported that she has been free from any pain or limp, and is able to be about as freely as any one, except that she occasionally has slight pain in the hip if overtired.

Case IV. Woman, thirty years of age, presented herself with the symptoms of commencing hip disease. The characteristic flexion, limping in gait, stiffness at the hip were present, and there was a complaint of pain at the hip and knee, which was aggravated on moving the hip. The patient stated that she had pain at night in the limb, and that the symptoms had persisted for eight months. A diagnosis of functional rather than organic trouble at the joint was made on a second examination (though beginning hip disease was suspected at the first), based on the fact that the limb was moved by the patient herself much more freely than would be consistent with any active inflammation at the hip-joint, that no muscular atrophy of the thigh was present although the affection had persisted for eight months, and that although there was stiffness in the direction of flexion and extension of the right thigh, as compared with the left the stiffness in abducting the limb was not marked. Confirmatory of this opinion was the fact that the patient had been for some time under the observation of Dr. C. F. Folsom for what was manifestly hysterical stiffness of the right arm, the symptoms of which had disappeared as those of the hip became prominent. The patient entered a hospital, and the report of the attending physician as to the subsequent course of the case tends to confirm the diagnosis.

Case V. S., girl, twenty years of age, a domestic, complained of some pain and tenderness on the outer side of the right knee. The pain was located, not in the joint proper, but to the outer side, and was not severe enough to keep the patient awake during the night, but was constant whenever weight was thrown upon the limb. The patient had evidently been overworked, and was in rather a nervous condition, though no evident exaggeration of symptoms was noticed. Her appetite and digestion and general nutrition were good. There was no swelling at the knee, and no stiffness or limitation to motion.

The patient was taken from her work, put in the Samaritan Hospital for a few months, sent out to the country for a month, and returned somewhat improved in general symptoms, but still complaining of pain at times in her knee. She was allowed to resume her work as a domestic, taking lighter work, and her pain gradually disappeared. On resuming harder work she began to complain again at times of pain at the knee.

Case VI. B., a young lady, thirty years of age, a school-teacher, of healthy appearance, was referred to me through the kindness of Dr. Wing. Three years before the patient was suddenly seized with a spasm of the left lower limb, causing it to be drawn up on to the abdomen, and flexed strongly at the knee. There was intense pain at the time in the thigh, knee, and hip, and the limb could not be drawn into a normal position. This condition remained unchanged for three weeks, when some improvement was noticed. Her regular medical attendant discovered a uterine displacement, and applied a pessary, which relieved her almost immediately, so that she could move her limb freely without stiffness. If, however, the uterine supporter was removed or not properly fitted she was liable to frequent attacks of spasm in the limb and pain in the knee. She has been obliged to travel about, and has been in the hands of several physicians, and has worn various pessaries, and she finds that if the uterus is well supported no "cramps" of the leg take place. If not she is liable to frequent attacks of tonic or clonic spasm at the knee. Pain in her knee is worse just before her menstrual attack. The patient was found to walk without any limp, and could stand on the

affected limb; could flex to a right angle, but not beyond; could extend fully, though the motion was slow and accompanied by some muscular tremor. Marked superficial tenderness was observable over the knee, but there was no swelling and no muscular atrophy of the muscles of the thigh. The tenderness was not localized. The condition of the limb had remained about the same for two years, and was not found changed on a subsequent examination several months later. The patient did not come under treatment.

Case VII. Mrs. F., a widow, fifty years of age, was seen by me at the request of Dr. Bixby. She had been under treatment by Dr. Bixby for several months for nervous prostration, with hysterical manifestations. She had suffered from attacks of severe pain in the left side, and her left leg had been drawn up and flexed at a right-angled position and had remained in this position for one and a half years. There was no history of arthrites or of pain or swelling of knee. Under ether the limb was forciby straightened, a few slight adhesions giving way. The limb was kept in a straight position by a plaster-of-Paris bandage, and later a ham splint. The patient subsequently was allowed to walk about with crutches, using a ham splint at first, and at the present time, two years later, walks about with a straight limb without crutches or splint, but complains still of occasional pain and weakness in the left side and limb.

Case IX. A boy, twelve years of age, was referred to me by Dr. Doe for examination. Before he had been put off a horse car by a conductor, and claimed to have fallen and struck his right side. A few weeks afterwards he complained of pain in his limb. He was kept in bed for a short time, and then urged to go about. He limped badly, with the foot turned out to a marked degree, and this had continued for two months. On examination no evidence of disease at the knee, hip, or ankle, and no paralysis of muscles could be found. The foot, however, assumed the position of a valgus deformity, causing him to limp as if suffering from valgus of the foot following infantile paralysis or disease of the tarsus. He was in a nervous condition, and cried immoderately during examination. His condition, however, improved under tonics and exercise, and he was finally reported six months later to have entirely recovered.

This class of cases is of course analogous to the well-known affection which has been termed spinal irritation — characterized chiefly by a tenderness in the spine and disability to a greater or less degree. The two following cases will serve as an illustration: —

Case X. A young girl, eighteen years of age, on account of great pain in her back, took to her bed, being unable to walk about. Her previous history had been one of good health, and she gave no evidence of an excitable temperament. Her mother had died in an insane asylum, but the girl had been sensibly brought up; she had grown very rapidly in the three preceding years, was tall, rather thin, and without much color. Her general condition was otherwise good. On examination of the back nothing abnormal was observed, except extreme hyperæsthesia all along the spine. The patient stated that she was unable to stand, but could sit up in bed.

The family physician had, recognizing the nervous nature of the affection, endeavored to oblige her forcibly to stand, but without success. The patient was treated at home and advised to remain entirely recumbent for a short time and then given slight exercises, increasing in amount each week. At the end of a month she requested to be allowed to sit up; at the end of a few months she began to walk about; in a year she had entirely recovered her strength; and a year later took her position as an active member of society.

Case XI. A girl, fourteen years old, had had caries of the spine in the lower dorsal region when five years old, from which she appeared to have recovered fully after three years, being able to run about readily and attend school; at about the age of puberty she, however, began to complain of pains in her legs, and her physician, fearing a return of her symptoms from caries, advised her to be kept in a recumbent position in the way in which she had been before successfully treated. This was scrupulously done, and for a year the girl neither sat nor stood up. At the end of this time she was unable to stand up but was able to sit up. She complained of a burning sensation in the back and intense hyperæsthesia, of pain and weakness in the legs, and of occasional severe headaches. The patient was gradually taught to stand and to walk with crutches, this being brought about by placing her flat upon a frame which each day was raised more and more, so that she was gradually put upon her feet, supporting herself from her arms with crutches. She was then taught to walk, and soon learned to walk with crutches quite freely.

She was then taken home from the St. Margaret's Home where she had been staying. Her condition remained substantially the same; she remained absolutely wedded to her crutches, though in walking she did not practically use them, bearing no weight upon them; if, however, they were removed she sank to the floor. She was in good general condition. She had worn a leather jacket as a support for her condition of caries of the spine, and felt herself unable to sit up without it. In this condition she was induced to visit a shrine at a Catholic church and offer prayers daily, walking to the church from her house (a comparatively short distance). In the midst of her prayer on the ninth day she exclaimed that she felt strong, and discarded her crutches and jacket, and has since walked without them. She is said to have had no relapse since then.

The above cases are undoubtedly examples of slight conditions of that peculiar state or temperament which has been misnamed hysteria. Whether any local strain has been in any way influential in determining the local manifestations in the limb of the peculiar condition of the nervous system remains a field for speculation. The writer will not venture on any theory as to the pathology of this class of disorders. The symptoms certainly appear sometimes in patients manifesting few of the usual characteristics of well-marked hysteria; certainly in all which have come under the writer's observation a well-balanced nervous system did not appear to be present. It was inferred that an undue sensitiveness to external irritation was present. A distinct feigning was not observable in the cases here reported. The fact that the consciousness was directed unduly upon certain sensations, and that the importance of these sensations was unconsciously exaggerated, undoubtedly plays an important part in producing this hypersensitiveness, but another factor must coexist. The sound of an electric bell varies not only with the quality of the enunciation, but also with the circumstances making the electric current strong or

weak. The sensation of pain may be acute from a slight irritation, either because the mental attitude may be one of exaggerated expectancy or because the ganglionic cells of the cord receiving and transmitting the irritation are in an unduly sensitive condition. How far the state is due to a cerebral condition or to one of the spinal cord will not be discussed here.

The diagnosis, it scarcely need be said, is sometimes quite difficult, and the details vary necessarily in each case. In some cases a diagnosis cannot be made on a single examination. As a rule, however, the recognition of purely functional affections can be based on the absence of the positive symptoms of joint disease and on the medical inconsistencies of the symptoms present.

Muscular atrophy is present in an early stage of true affections of a joint, even when the disability of the limb is slight. A marked diminution of faradic electrical contractility of the muscles is also present in joint affections at a comparatively early date in the history of the disease. In the so-called hysterical affections atrophy is only seen where there has been a marked disuse of the member, and the diminution of the faradic electrical contractility corresponds to the amount of muscular atrophy. Furthermore, in true joint affections a certain proportionate relation exists at the different stages of the affection between the symptoms of pain, tenderness, position of the limb, amount of stiffness, and the way in which the limb is moved. This can be readily recognized by any one who has watched a number of these cases. In the functional troubles of the joints this relative proportion is not preserved. More limping, or muscular spasm, or pain is present than would be expected at a certain stage of a true arthritis indicated by the position of the limb or the limp in gait — or the reverse may be true.

The treatment should be the reverse of routine, and necessarily equally good results will be brought about by impressions produced in different ways. Of cases here reported where treatment was attempted the basis of treatment was the acceptance of the fact that the symptoms indicated to the patient an actual and not an assumed condition. This condition was met with the enforcement of rigid rules, followed by a gradual relaxation of these rules and a gradual enlargement of the scope of action as the patient accepted the ability of freer action. In the severer cases absolute isolation from the indulgent atmosphere of sympathizing friends is essential. The patient must be reduced to an infantile state and gradually trained to exertion and endurance. Of course in lighter cases such extreme discipline is not necessary. Massage, electricity, ice, and heat to the spine, forced feeding are of undoubted value in certain cases, but the writer is doubtful whether they are to be looked upon as direct remedial agents and not rather as mental alteratives, supplying new sensations, or temporizing agents, while the nervous system is gaining its poise. Purely local treatment, such as cauterization, counter-irritation, is usually harmful as it concentrates the patient's attention upon local sensations, and appliances are to be avoided except in certain cases to temporarily correct vicious positions.[1]

A CASE OF STRANGULATED UMBILICAL HERNIA.[2]

BY H. L. BURRELL, M. D.

ON December 12, 1883, H. K., aged fifty-two, a woman weighing 230 pounds, entered the Carney Hospital with a strangulated umbilical hernia. The tumor was livid in spots, had a doughy feel and tympanitic resonance. The hernia had existed for years, but the patient had always been able to reduce the mass until sixty hours before entrance. There was no impulse on coughing, and the tumor presented a median raphe not unlike that existing on the scrotum. At the juncture of the skin of the dependent portion of the tumor with that of the abdomen an ulceration existed not unlike that which takes place at the junction of the scrotum with the perinæum in extravasations of urine. Since the hernia "had been caught" the patient has had intense abdominal pain, continuous vomiting, and no dejection. The temperature was 101° F.; the pulse 150, small and wiry; the face was pinched, and patient was very anxious. The dangers of operating and the probabilities of non-interference having been clearly explained to the patient she was etherized, and taxis was tried without avail.

Operation. An incision was made, three inches in length, at the junction of the superior part of the tumor with the abdomen, extending well up on the abdomen. The division of the skin, which was very thin, was followed by a serous exudation, showing that a few more hours would have produced sloughing. The hernia was liberated, after some difficulty, by dividing the constricting ring. Owing to the depth of the incision, and the tenseness of the overlying tumor, it was found impossible to divide the constriction from within outwards; it was, therefore, divided with much care from without inwards. The peritonæum was, from necessity, opened. The hernia was reduced, leaving considerable adherent omentum remaining. This was removed by ligating it in pieces. The redundant skin which had covered the hernia was then removed, leaving an abdominal section four or five inches in length. The hæmorrhage was slight and easily controlled. Small sponges were kept in the bottom of the wound to prevent the blood from trickling into the abdominal cavity. The wound was brought together by three wire sutures, which included the peritonæum and whole abdominal wall with intervening superficial sutures. The wound was dressed with bichloridized gauze, a binder was adjusted, and patient was placed in bed.

December 13th. Came out of ether well. No pain. Free movement of the bowels during the night. Pain to be controlled by morphia.

December 14th. Had a loose dejection during the night. No morphia necessary. Has taken a fair amount of nourishment, and vomited but once. Patient is very stupid.

December 15th. This A. M. patient lies on back; face flushed; pupils contracted; very stupid. Temperature 100° F.; pulse 122. Abdomen not tender. On removing the dressing the wound was found to be united superficially, but on pressure an offensive, sanious fluid exuded from the lips of the wound. This came from the large abraded surface which existed owing to the removal of the adherent omentum. All

[2] Read before the Surgical Section of the Suffolk District Medical Society, May 7, 1884.

the superficial and two of the deep wire sutures were removed. The wound was thoroughly syringed out with chlorinated soda, and a drainage tube was introduced into the depth of a cavity which the hernia had formed by insinuating itself into the adipose tissue, and which extended upward and to the left, external to the recti muscles. Wound packed with iodoform.

The wound was syringed out night and morning, and packed with iodoform, the patient having numerous dejections daily, taking a fair amount of nourishment and stimulants, requiring no opiates, and sleeping the greater part of the time until December 21st, when the remaining wire suture was removed. On taking out the drainage tube a mass of necrosed tissue was removed. Flaps were much undermined.

The temperature remained practically normal, and the wound looked very well at each morning dressing, but an area on the left side seemed to remain *in statu quo*. On January 5th, in dressing the wound, on introducing the dressing forceps to remove a supposed piece of necrosed tissue a small piece of sponge, the size of a chestnut, was removed. This sponge had been packed beneath the flaps to check hæmorrhage at the time of the operation, and to my chagrin had been inadvertently overlooked in uniting the wound, and explains the persistency of the discharge.

On January 28th the temperature rose to 102° F.; the following day it reached 103.5° F., and the patient had headache and nausea. The iodoform which had been used in dressing the wound was omitted, and the following morning the temperature was normal, and the headache and nausea had ceased.

The patient's convalescence was delayed, but she left the hospital on March 5th with a perfectly united abdominal wall. She was advised to wear an abdominal support for a time.

The justifiableness of further operative interference arose when the strangulated intestine had been liberated and returned to the abdominal cavity. Had the case been left to itself at that time we can readily see how difficult it would have been with practically a punctured wound of the abdominal parietes, through which the operator had been able to relieve the constriction, to have prevented the natural drain of fluids into the abdominal cavity. For this penetrating wound of the abdomen was substituted an abdominal section, five inches in length, in the median line, the adherent omentum was removed, the abdominal walls, including the peritonæum, were subsequently brought accurately in apposition, thus making an effort which, in this instance, was successful, to render permanent the relief to this ever-present danger.

— According to the *Lancet*, at Bridgewater, England, on the 5th of September, a laborer fell into a trance, and his wife, thinking he had died suddenly, made preparations for the funeral. The vicar, however, on being informed of the facts, inspected the supposed corpse, and refused to allow it to be buried, since it was not cold enough to satisfy him that actual death had taken place. The body was placed in a coffin and conveyed to the church, where it was frequently visited by the vicar and others. On the 8th of September a slight movement occurred, the man was removed to bed, and has since slowly recovered.

THE CURE OF CROOKED NOSES BY A NEW METHOD.[1]

BY JOHN B. ROBERTS, M. D.

I PRESENT this patient to the Society to show the manner in which I treat the very disfiguring lateral deformity of the nose, so often seen after falls or blows which have fractured the septum and cartilages. The method is, I believe, original. It is certainly attended with very little inconvenience to the patient, who, after recovering from the anæsthetic, can at once attend to his occupation without wearing any apparatus to call attention to the surgical procedure by which his crooked nose is being made straight and shapely. The usual advice given to patients with deformed noses, from nasal fracture sustained in childhood or later, is to undertake no surgical treatment, but to become reconciled to the disfigurement of feature as best they may. This is, I am sure, improper advice. The cosmetic objection to a crooked nose is cogent; and, moreover, obstruction of one nostril, from the displaced cartilages, is a frequent accompaniment of such lateral deviation of the tip of the nose.

This man sustained, ten years ago, a fall upon his face, from which he recovered with the end of the nose bent to the right, and with considerable obstruction of the left nostril. I operated on him day before yesterday. You see now a straight nose, and nothing to call attention to the operation except a small piece of black court-plaster a little to the right of the nasal bridge. Just within the right nostril close inspection reveals the head of a pin, situated on the side of the septum, near the columella. The method of operation, therefore, is certainly not objectionable on account of making the patient unpleasantly conspicuous during treatment. This evening I merely wish to show the man, and refer to my method of dealing with such cases, because at a later time I hope to bring the subject of curing nasal deformities before the Society in a more formal and elaborate manner. Then, I may have no patient undergoing straightening of the nose to illustrate the remarks.

Replacement of the deformed structures in this case was very simple. With a scalpel introduced through the left nostril I perforated the cartilaginous septum at its upper and back part, and made a long incision through it in a direction downwards and forwards. This permitted me to push the whole cartilaginous portion of the nose to the left, and overcome to a great extent the lateral deformity. To retain the parts in this position I introduced a steel pin, about one and one fourth inch long, into the right nostril, and passed it completely through the anterior and upper segment of the divided septum, near the columella. Having the movable portion of the septum thus transfixed, I was enabled, by carrying the head of the pin to the left, to move the anterior part of the nose to the left, and retain it there by imbedding the point of the pin deeply in the immovable cartilaginous septum and mucous membrane at the back of the left naris. In other words, I incised the deformed cartilage, and pinned it in position very much as you would pin a flower in the button-hole of a coat. There still remained a little deflexion of the end of the nose to the right, which seemed to be due to mal-position of the lateral cartilage

[1] Read before the Philadelphia County Medical Society, September 17, 1884.

close to the right nasal bone. With a tenotome in the right nostril, I pared the cartilage loose, without perforating the skin, and pinned the parts over to the left by a second pin inserted from the cutaneous surface of the dorsum on the right of the median line. The point of this pin was fixed by having its point imbedded in the tissues of the left naris. It is the head of this second pin that is covered by the small square of court-plaster. The correction of the angular deformity of the septum removed most of the occlusion of the left nostril, which had greatly annoyed the patient.

I have thus given an idea of the method, which has, I believe, great capability for relieving unsightly nasal deformities. The novelty consists merely in pinning the parts in position until cicatrization takes place. Endeavors have occasionally been made, as by Mr. Adams, Dr. Weir, and others, to hold deflected noses in position, after operation, by the use of clamps, rods attached to the forehead, adhesive plaster plugs, and similar devices. All of these are objectionable, because so conspicuous and troublesome, and would probably be adopted only in instances of great deformity. The pin method, however, leaves no noticeable scar, is not troublesome to the patient, and is applicable, therefore, even to those slight deformities, whose chief annoyance is an æsthetic and cosmetic one. I leave the pins in position for about two weeks.

A few years ago Dr. Mason, of Brooklyn, recommended the use of steel needles to hold the nasal bones in position, when, after recent comminuted fracture, it was difficult to keep the fragments sufficiently elevated. He transfixes the nose below the depressed fragments, and carries a piece of plaster or a rubber band across the external surface of the bridge from one end of the needle to the other. The needle acts as a girder to tie the base of the nasal arch and prevent its falling in. This is a different use of the pins or needles from that which I am describing, and for a different purpose.

I have pins of lengths varying from one inch to two and one fourth inches, and with flat heads, so that there will be little projection under the court-plaster to attract attention when the patient is in public. The heads are square, that the pins while imbedded may be, if necessary, readily rotated by the fingers.

When the deformity is in the osseous portion of the nasal bridge section with small chisels is usually necessary. Discussion of this topic, however, would carry me beyond the limits of the present subject.

Free incisions are essential in obtaining good results in cases of nasal deformity such as was exhibited by this patient. The surgeon must not spare the knife and thereby spoil the nose. Secondary operations may sometimes be required to get the best results. If a simple incision did not allow proper adjustment I should excise portions of the cartilage with the oval punch or the scalpel, or make multiple stellate incisions with the stellate punch, and so produce general flexibility of the cartilage.

Recurrence of deformity would, I think, be less likely to occur after free incision, pinning, and cicatrization than after simple dilatation with or without incision with the stellate punch.

— A recent writer in the *Medical News* (August 30th) speaks of a case of urticaria causing miscarriage.

NOTES OF A CASE OF POISONING FROM MRS. WINSLOW'S SOOTHING SYRUP.[1]

BY A. B. HIRSH, M. D.

WITH the object of adding my quota to the list of serious accidents resulting from the indiscriminate sale of secret medical preparations, I have gathered the notes of the following case: —

Mrs. A. H. L. took her twenty months' old boy to visit some friends, and while there they (all unknown to her) fed him some unpeeled apple and other indigestible material. Being colicky all that night and next morning she was persuaded by a "friend" to purchase a two-ounce vial of the nostrum sold as "Mrs. Winslow's Soothing Syrup," and of this gave him half-teaspoonful doses, as the directions called for, although she insists half of each quantity was spilt through his struggling.

He took, therefore, the first dose at four o'clock on Sunday afternoon (August 24th) and, there being no effect, another at eight; then dozing but not sleeping from this time till three next morning, the pain starting him again to whining, he was dosed at five; still crying on, three quarters of an hour later the final similar amount was administered. The mother soon became alarmed at the marked stupor which had now set in. He would touch none of the breakfast placed before him, Mrs. L. said; although sitting upright in his high chair, his head hung listlessly, and he recognized nobody.

I saw him at 7.45 A. M. and found marked symptoms present of poisoning by some narcotic drug. The pupil was contracted down to the typical pin-head; stupor was unmistakable; respiration was very slow, gasping, and shallow, while at irregular intervals he would take two or three rapidly succeeding deep sighs; the pulse was rapid and small; the extremities were cold throughout the case. Taking all these symptoms into consideration, and the fact that the breath bore the peculiar odor of an opiate, I felt warranted in treating the case for one of poisoning by some preparation or derivative of that drug.

The stomach and bowels were emptied at once; frequent cold sponging was ordered, with wet cloths placed on the nape of the neck whenever great trouble existed in keeping him awake. Tr. belladonna was given hourly in aqueous solution. The parents were directed to keep him awake by all means.

By noon he would begin to lift the eyelids a little, but relapsed into a sort of doze by two P. M. Despite all their efforts he fell once more into a stupor by six. Calling about this time, I insisted on the mechanical exercises being continued, feeling encouraged by the somewhat improved breathing, and that I succeeded, a little while later, in arousing him. As the pupil had now slowly begun to dilate, the medicine was ordered to be given every half hour, or twice as often as before. By eleven he began to lighten up, and on calling, half an hour later, I found him languidly trying to push his ball around the table upon which he sat. The pupils were widely dilated, and respiration free. He was allowed to sleep, with slight interruptions, from midnight until six A. M., after which the child showed his great thirst by frequent demands for ice-water. Incoordination of the voluntary muscles now became noticeable, and continued until next morning. A typical

[1] Read beore the Philadelphia County Medical Society, September 17, 1884.

belladonna rash was now likewise beautifully shown, also to disappear in time. He slept for two hours about noon, being exceedingly irritable afterwards, but, excepting the use of a tonic, required no other treatment.

As stated in the beginning of the notes this case is merely placed on record to help expose an existing evil, believing that continuous agitation will finally induce the intelligent public to demand the regulation of the sale of patent medicines, a fact concerning which there never was any doubt in the profession.

A fatal result would inevitably have here occurred had no treatment been instituted, and I feel convinced that many such cases happen in our midst which should be reported.

The case is the more pertinent at this time when any fakir or shop-keeper may legally retail unlabeled poisons in the guise of patent medicines, while one of our inconsistent laws is now being so interpreted as to inform the patient that, in very many cases, his doctor has prescribed him medicine containing poison.

DRS. A. T. CABOT and H. L. BURRELL reported

CASES OF STRANGULATED UMBILICAL HERNIA.[1]

DR. HODGES said that there was no doubt that the operation for the relief of strangulated umbilical hernia was more successful now than formerly. At the time when the paper referred to by Dr. Cabot was written the speaker took a much more conservative view of the operation than now, as the advance in antiseptic methods of operating has probably greatly lessened the mortality. Bringing the peritoneal surfaces of the abdominal wound in apposition when sewing up was often done in former times, to his certain knowledge as early as 1852, when the operation was followed by a much greater percentage of deaths than now. Hence we must infer that this method of uniting the edges of the abdominal incision is of less importance than strict antisepsis. Dr. Hodges also spoke of a method of treatment of reducible umbilical hernias, first suggested by Dr. H. J. Bigelow. The hernia is reduced, the sac invaginated and held in place by a small stick fastened at right angles to the surface of a small board, the end of the stick being wrapped with cotton and pushed through the ring. The whole is then firmly held in place by means of a swathe. This is worn for two days, and then fresh cotton saturated with caustic ammonia is applied in like manner, the sac becomes excoriated, and on withdrawing the stick the cutaneous surfaces unite and the ring is closed with a mass, probably shaped like a shirt stud. The speaker had that day discharged from the hospital a patient, a very fat woman with a large hernia, cured by this method. This case and the case reported by Dr. Bigelow are the only two on record.

DR. CABOT called attention to the fact that the best reported results in umbilical herniotomy were those of Lawson Tait, who disregards antiseptic methods in his operations.

DR. GREENE spoke of the difficulty in making any mechanical appliance which will keep a large umbilical hernia in place, and the great value of any operation that shall, without danger to the patient, radically cure the hernia.

DR. H. L. BURRELL read a paper on

UNILATERAL ATROPHY.[2]

DR. HODGES remarked that cases of asymmetry were probably much more common than is generally supposed. It is often noticed in the face, and he could recall three persons among his acquaintances where it is quite marked.

DR. JEFFRIES WYMAN called attention to the fact that the legs were very frequently of different lengths, and this should be remembered when looking for shortening after fractures.

DR. R. M. HODGES read a paper on

EXCEPTIONAL FATTY TUMORS.[3]

DR. CABOT mentioned a case sent in from the outpatient department for operation, supposed to be a ganglion on the back of the middle finger, which proved to be a fatty tumor.

NEW YORK ACADEMY OF MEDICINE.

THE THREE TONSILS, SOME PRACTICAL SUGGESTIONS IN REGARD TO THEIR STRUCTURE, FUNCTION, AND DISEASES.

AT a stated meeting of the Academy held Thursday evening, October 2d, DR. J. H. BOSWORTH read a paper on the above subject. By the three tonsils are to be understood the two glandular masses found between the pillars of the fauces, to which the name tonsil is usually applied, and the mass of glands found in the vault of the pharynx, sometimes designated the pharyngeal tonsil. He then pointed out several errors in the description of the faucial tonsils as usually given in the books. Thus, he said, they were not covered by a fibrous sheath; though underlying them there was a more or less dense connective tissue layer, continuous with the submucous layer, which underlies all mucous membranes. The tonsil was not an "almond-shaped organ," as a rule, but was of whatever shape the morbid process which had caused its growth might give it. It was not an organ of the body in the sense that the liver and spleen were organs, and, therefore, in this sense had no especial function to perform in the economy. In the healthy throat there were virtually no tonsils, these so-called organs being merely the result of a morbid process. In a condition of health the normal aggregations of glands in the pharyngeal vault and between the pillars of the fauces did not project prominently from the mucous membrane, and hence in a perfectly healthy state their existence was not easily demonstrated by gross inspection. The mucous membrane of the upper air-passages, however, was peculiarly liable to be the seat of morbid action. It was a very noticeable clinical fact also that while

[1] See pages 363 and 368 of this number of the JOURNAL.

[2] To be published hereafter.

[3] See page 361 of this number of the JOURNAL.

in adults it was the mucous membrane proper which was most liable to be the seat of disease, in children it was the glandular structures which were especially susceptible. The tendency of chronic inflammatory processes was towards hypertrophy, and hence it was found that a moderate hypertrophy of these glandular masses was of exceedingly frequent occurrence in the young, constituting in the one position so-called enlarged faucial tonsils, and in the other an enlarged pharyngeal tonsil.

The pharynx, he went on to say, was really composed of two cavities, differing materially in structure and function, the upper pharynx belonging to the air-tract, and the lower pharynx to the food-tract. The lower pharynx was very scantily supplied with glands, and yet in the performance of its function it demanded an abundant supply of mucus. In order to compensate for the deficiency it was surrounded on three sides with large aggregations of glands, constituting the three tonsils referred to. The sole and only function of these masses of glands was, he believed, to supply mucus to moisten and lubricate the lower pharynx. The resemblance of the faucial and pharyngeal tonsils was so strong that the only difference in structure was easily accounted for by the fact that the pharyngeal tonsil was protected from any impact of foreign substances, and was, therefore, of a more soft and spongy consistence than the faucial tonsils, which, being subjected to much harsher usage in the act of deglutition, contained a greater amount of, and more firmly organized, connective tissue.

From a pathological point of view still further grounds for grouping the three tonsils together were found, for the same morbid processes which occurred in the faucial tonsils were met with in the pharyngeal tonsil, namely, acute inflammation, chronic inflammation, resulting in hypertrophy, acute follicular inflammation, croupous inflammation, and diphtheritic inflammation. Acute tonsillitis was a name generally given to quinsy, but quinsy, he claimed, was not a disease of the tonsil, but an inflammation of the cellular tissue of the soft palate or neighboring parts, phlegmonous inflammation, in his opinion, not occurring in the tonsil. As a matter of fact, therefore, the only form of acute inflammation met with in the tonsil was a catarrhal inflammation, namely, one attended with hyperæmia, swelling, and hypersecretion. This was usually described under the term subacute inflammation, and it occurred in the pharyngeal with the same frequency as in the faucial tonsil, being attended with the same mild constitutional disturbance, and caused, as a rule, by exposure to cold. The main predisturbing cause was an enlarged pharyngeal tonsil, just as enlarged faucial tonsils were the main predisposing cause in subacute inflammation of the faucial tonsils. It could easily be understood how, in the case of a mild inflammatory process occurring in the pharyngeal tonsil, the symptoms would be mainly nasal. The attack was usually regarded as an acute coryza, but this, he believed, was an error, since acute inflammation of the nasal mucous membrane in children was very rare. As before remarked, in children the glandular structures were the parts generally attacked, and not the mucous membrane proper, so that their colds, if in the throat, were in the faucial tonsils, and if in the nasal passages were in the pharyngeal tonsil.

He then described acute follicular tonsillitis, in which the constitutional symptoms were very much more severe than, in his opinion, could be accounted for by the amount of local inflammatory action, and claimed that this disease was an essential fever, with a local manifestation in the throat, something in the nature of one of the exanthemata. The same affection, he had found, frequently occurred in the pharyngeal tonsil. Croupous tonsillitis he regarded as identical with follicular tonsillitis, except that the eruption was more marked or efflorescent. The exudation, which in the latter confined itself to the crypts of the glands, in the former filled and overflowed them, forming a continuous membrane. If this were detached from the surface there would be found beneath it the appearances of the follicular disease. A similar membrane, with its appearance attended with the same general symptoms, he had frequently observed on the pharyngeal tonsil.

Having referred to diphtheritic tonsillitis as always occurring in connection with the blood-poison of diphtheria, he went on to speak of hypertrophied tonsils. Hypertrophy of the faucial tonsils, he said, gave rise to a train of symptoms, which were mainly due to the mechanical presence of these glandular masses in the fauces. They occurred mostly in young people, and their development was attended by the occurrence of repeated attacks of subacute inflammation or ordinary catarrhal sore throat, while they showed a tendency to subside at puberty. Hypertrophy of the pharyngeal tonsil had been described by many writers, usually under the heading of adenoid tumors or vegetations at the vault of the pharynx, and in all its aspects, except in its location, it was identical with the faucial disorder. In this view, then, enlarged tonsils in either region were simply masses of diseased glands, whose function had, in the main, been abolished or perverted by the morbid process which had fixed itself upon them. If the hypertrophic process was limited, and the tonsils were of small size, giving rise to no untoward symptoms, they required no treatment, but if the hypertrophy had gone to the extent of developing a glandular mass, which by its presence interfered with the function of the parts, or which in any way gave rise to serious symptoms, he thought that there could be no question as to the proper remedy. They were diseased structures, and ought to be extirpated, for as regards any local medication he believed it to be absolutely inert in reducing genuinely hypertrophied glands. It was sometimes said that nature placed these tonsils in the throat, and that they should not, therefore, be removed, but the fact was that nature never did put them there. He then went on to speak of the operation of tonsillotomy, maintaining that the entire mass, and not merely a portion, should be removed. In children hæmorrhage never occurred, but in adults it was liable to be met with, although literature recorded not a single fatal case, with the exception of those in which the inexcusable blunder of cutting the carotid artery had been made. The best means of arresting hæmorrhage was the application of a wire heated to a dull red heat.

For three years he had maintained that quinsy was not a disease of the tonsil. The latter, it was true, often presented a red and angry appearance, but this was always secondary, and due to the fact of its nearness to the phlegmon. Again, the tonsil was occasionally very prominent, being lifted from its bed, and at times projecting far toward the opposite side of the fauces, but this was because the phlegmon was situated

behind it. The cause of quinsy he believed to be in very many cases the rheumatic habit, and the connection between the two diseases seemed to be confirmed by the results of the treatment which he had resorted to. For the last three years he had treated all his cases of quinsy by salicylate of soda, and of those which he saw within the first thirty-six hours the attack was thus aborted in a majority of instances, while in those in which the attack was not aborted suppuration seemed to be very much hastened. In several cases in private practice in which the quinsy habit had existed he had directed the patients to use this remedy immediately upon experiencing any symptoms of these attacks, and in no one of them had an attack occurred. He had also used, with success, in connection with the salicylates, the local application of bicarbonate of soda, as recommended by Dr. Barker. If in any instance the attack was not aborted by medication, or if the case was seen too late for this, the abscess was to be treated on general surgical principles, and the constant resort to digital examination was recommended as of material assistance to the medical attendant. The suggestions which he had ventured to advance in the paper were based on convictions which were the result of a somewhat large experience, and in acting upon them he felt confident that he had obtained better results in the treatment of throat diseases than in following the older doctors.

The discussion of the paper was opened by the President, Dr. Barker, who said that he had formerly been in the habit of using large doses of quinine, in connection with opium, for the purpose of aborting attacks of quinsy, and that for the past four years he had employed, in addition, the local application of bicarbonate of soda. He regretted that he could not now recollect how or by whom this remedy had been suggested to him; but since he had resorted to its use he had not seen a single case which went on to suppuration, although in a number of instances he had not been called upon for advice until comparatively late in the attack.

Dr. Douglas said he was firmly convinced from his experience that quinsy was intimately associated with gout and rheumatism. He had met with it, however, more frequently in connection with the former than the latter, and had, in a number of instances, seen attacks of quinsy alternating with those of gout, one occurring one year and the other the next year. For many years he had been in the habit of using bicarbonate of soda in the treatment, not only in the manner suggested by Dr. Barker (applied on the end of the finger), but also as an injection thrown into the posterior nares. He believed that Dr. Bosworth was correct in his statement that the tonsils did not appear at all to the eye in the healthy throat, and the same was true of the group of glands at the base of the tongue, which were also liable to become hypertrophied as the result of disease. He could not agree with him, however, that these abnormal structures could not be removed except by means of the knife. By a course of mild and gentle treatment they could be effectually removed, though the process was a long and somewhat tedious one. He was in the habit of using for this purpose a combination of camphor with salt and ammonia; employing five parts of the mixture to the hundred of sugar of milk.

Dr. Frank Hamilton was inclined to think with Dr. Bosworth that these excrescences ought to be removed, and that this could be best accomplished by means of the knife. But at the same time the fact was not to be forgotten that they were only exceptionally met with after the age of twenty-one; and it had occurred to him that perhaps the good results which Dr. Douglas had noticed in cases where the operation was not performed were in reality due more to the lapse of time than to the remedial measures adopted. Except in cases where the tonsil was in a state of acute inflammation, and in those where the hæmorrhagic diathesis was present, he agreed with Dr. Bosworth that the operation was unattended with danger. When hæmorrhage did occur, however, the best and promptest way of controlling it was the application of cold in the form of the ice or snow cravat.

Dr. A. Jacobi made some remarks on the subject of tonsillotomy, in which he said that when tonsils had become permanently enlarged they were amenable to no other treatment than by the knife, and that the only satisfactory way of controlling hæmorrhage when it occurred after the operation was the compression of the bleeding surface by means of the finger. In regard to follicular tonsillitis he could not agree with Dr. Bosworth that the disease was an essential fever, and in conclusion he pointed out the danger to the community of mistaking mild cases of diphtheria for it.

Dr. Weber had never met with any cases of quinsy in which there appeared to be any connection whatever with rheumatism or gout, and was inclined to believe there was danger of following out the English idea too far in this respect. As to the treatment by internal medication he had had no experience, being always accustomed to evacuate the abscess as soon as possible. Hence he was in the habit of making frequent digital examinations.

Dr. Barker mentioned the papers on the use of guaiac in quinsy published in the early numbers of the *London Practitioner*, and stated that he had tried the remedy faithfully, but without any satisfactory results; after which Dr. Fruitnight said that in three cases he had succeeded in aborting attacks of the disease by giving one drop doses of tincture of aconite root every hour for several hours, as suggested by Sidney Ringer.

Dr. Brandeis had also used the latter with success, but in connection with fifteen or twenty drop doses of ammoniated tincture of guaiac. In regard to the tonsils, he was satisfied that these organs served a purpose in the economy, and yet at the same time he did not doubt that a diseased tonsil was worse than none at all. Hence he believed that it ought to be removed, and he then proceeded to speak of the advantages of the tonsillotome over the ordinary knife for this purpose.

Dr. Jarvis spoke of the danger from hæmorrhage of removing with the knife hard or cirrhotic tonsils, such as were frequently found in syphilitics, and advised that the snare or cautery should be used in such cases. As a rule, he thought it best that the entire body should not be removed, as he believed that the tonsil served a useful purpose in forming a pad for the protection of the carotid artery from injury.

Remarks were also made by Drs. Alfred C. Post and J. L. Corning, and the discussion was brought to a close by Dr. Bosworth.

— The Pope has given $200,000 for the erection of a new hospital at Rome, near the Vatican.

Recent Literature.

Text-Book of Medical Jurisprudence and Toxicology. By JOHN J. REESE, M. D., Professor of Medical Jurisprudence and Toxicology in the University of Pennsylvania, etc. Philadelphia: P. Blakiston, Son & Co. 1884.

Professor Reese sets forth the scope and aim of his book with sufficient clearness in his preface. Having become convinced by an "experience of over twenty years as a public teacher of this branch of science, that students who desire to acquire a knowledge of medical jurisprudence are too often deterred from their purpose by being confronted by the ponderous works of recognized masters," he has "endeavored to condense in a handy volume all the *essentials* of the science and to present the topics in a simple and familiar style." Under these limitations, deliberately established, the author has produced an excellent book. All the subjects usually included in a treatise on legal medicine are considered with more or less fullness and always attractively. But it is a fair question whether, in thus confining himself, the author has done himself or his themes the fullest credit. The main defect of the volume seems to us to be this intended leanness; in the steady purpose to "condense," the author has trimmed his composition too often to an extent that suggests unpleasant emaciation. It is as if one of a class of bright students taking well-written notes of the professor's own lectures had published those notes and called the product a text-book. In other words, the book is suggestive rather than exhaustive. One would hardly seek these pages first of all in the list of works on medical jurisprudence, if occasion demanded of him a preparation for creditable appearance in a medico-legal case; he would naturally turn to other authorities whose writings are the substance of which this volume is a thin shadow. Both the lawyer and the doctor, when "compelled to cram for the occasion" of an impending trial (as the author expresses it), would scarcely rest satisfied if limited to the "essentials" here provided. And we meet repeatedly in the book such clauses as, "These [topics] cannot be farther enlarged upon here;" and "In a work like the present it would be impossible to enter into a full discussion of the subject;" as if the author himself felt hampered by his self-imposed barriers.

Nevertheless, within the limits described, an attractive and instructive volume is the result. The phenomena and signs of death, the details of the medico-legal autopsy, the means of identification of the living and the dead, deaths from wounds, burns and the various forms of asphyxia, by lightning, heat, cold, and starvation, — these are discussed in the first third of the book. In an introductory chapter on the relations of medicine and law, the author describes the "coroner's inquest" without a word of comment on its uselessness or a single reference to the successful measures which have been taken to supersede it with something better. "In all civilized countries," he writes, "a special officer, named the *coroner*, is appointed to investigate" deaths occurring under suspicious circumstances; there is no hint that uncivilized communities, like Scotland, France, Germany, and even benighted Massachusetts, get on very well without the services of the coroner.

The section on poisons, as might be expected from the author's enviable reputation as a toxicologist, is admirably written. Statements have occasionally crept into the text, however, which invite criticism. It is declared that "poisoning is the most frequent of all the causes of violent death (the casualties of war excepted)," and that the statistics of various countries show this to be true; this seems a most extraordinary declaration, and we hope that in future editions the statistics will be given in a foot-note. A poison is defined as "a substance which, when introduced into the body by swallowing, or by any other method, occasions disease or death; and this, as an ordinary result, in a state of health, and not by a mechanical action." We cannot but believe that a medical witness, using this definition in court, would find himself in trouble, if cross-examination were faithfully conducted.

In the sections relating to the vegetable poisons there is sometimes a want of definiteness; thus, the fatal dose of strychnia is given as from half a grain to a grain; that of tincture of aconite, from half a drachm to a drachm; while of atropia it is stated that "used hypodermically even in doses of one fiftieth to one tenth of a grain it occasions, at times, violent symptoms." Greater preciseness might have been expected.

Fœticide and infanticide, pregnancy, impotence, and rape receive clear and able treatment. The chapter on infanticide is particularly good.

Insanity, malpractice, and life insurance comprise the concluding portions of the book, and their medico-legal relations are well described. The author has no words of comfort for those who believe in "emotional insanity," and he analyzes with much skill the shortcomings of the legal doctrines and distinctions concerning mental disease and criminal responsibility.

A word of cordial praise should be bestowed upon the volume as a specimen of fine book-making; its typographical excellences impress the reader continually. The text is without the usual wood-cut illustrations, but these are scarcely missed in the presence of such clear type and tasteful execution. We heartily second the author's hope that his treatise may "encourage an increasing interest in the students of both medicine and law for that most important, but too much neglected, subject, forensic medicine." D.

Shakespeare as a Physician. Comprising every Word which in any Way Relates to Medicine, Surgery, or Obstetrics found in the Complete Works of that Writer, with Criticisms and Comparison of the Same with the Medical Thoughts of To-Day. By J. PORTMAN CHESNEY, M. D., etc., etc. St. Louis: J. H. Chambers & Co. 1884.

Dr. Chesney's book may be classed under the head of the "Anatomizing of William Shakespeare." He has endeavored to present "truly and faithfully every line and precept in Shakespeare's complete works which in the remotest sense bears upon the science and practice of medicine." The value of the conception seems to us more fairly open to criticism than the manner of execution. We think it would be better for Shakespeare and for the world of letters if the Shakespeare literature had never reached its present proportions, and were to receive no further additions other than

such as might drive into complete obscurity much of that already in existence.

The following passage from the pen of Richard Grant White, with which, in the abstract, we coincide, may be not inappropriately quoted in this connection: —

"More inflated nonsense, more pompous platitude, more misleading speculation, has been uttered upon Shakespeare and his plays than upon any other subject but music and religion. The occasion of which calamity is that of all subjects which are of general interest these are the most remote from reason, the most incomprehensible. Wherefore it is that certain men wish to show the world that they are the high-priests of this mystery, and can prophesy of it, and utter fine sayings about it, apocalyptically, by way of revelation. And there be literary scribes and pharisees whose function it is to stone prophets, and, by a sort of reverse action of nature, to build their tombs when they are dead and buried. Of which the result in this case is a mountain cairn of rubbish above the poet's remains, which tells little but of the multitude who have thrown their missiles there. Each, however, has written his name upon his stone, as who should say, Lo, it is I who have glorified the name and perpetuated the memory of this prophet.

"Besides these critics, and beside them, there arose enthusiasts who began to found a new literary religion, and to proclaim, Shakespeare is Shakespeare, and I am his prophet. Unlike the prophets of other religions, however, they did not accept and proclaim their divinity pure and simple, but set themselves to dissecting and anatomizing him, and telling the world what a marvelous mystery they had discovered this Shakespeare to be: how he saw more than eyes could see, and said more than words could mean; how wise he was, how great, how good; how grand in purpose, how absolute in execution; how perfect, how blemishless, because what would be blemish in others in him was beauty."

Nine chapters, under the following headings, make the volume: Obstetrics, Psychology, Neurology, Pharmacologia, Ætiology, Dermatology, Organology, Chirurgery, Miscellaneous. There are no separate chapters on gynæcology, laryngology, or otology.

The most that can be said of a book of this sort is that it may divert the compiler, and prove curious to some of those who consult it.

Practical Manual of Diseases of Women and Uterine Therapeutics, for Students and Practitioners. By H. MCNAUGHTON JONES, M. D., etc. New York: D. Appleton & Co., Bond Street. 1884.

Dr. Jones can hardly be said to have written a great work, nor does he profess to have done so. He has, however, given to the profession a useful little manual which will undoubtedly fulfill the purpose for which it was written. It will, we think, be of more value to the student than to the practitioner, for as it is necessarily so condensed as to contain only the most important facts, the points about which a practitioner would be in doubt would need a more extended treatise for their solution.

The author treats the subject of gynæcology from the stand-point of the general practitioner, and it is for him, and not for the specialist, that he writes. The result is a book more practical than technical. The first chapter, which treats of "anatomical facts bearing on gynæcological practice," is filled with practical hints which have suggested themselves to the writer, and which are very interestingly interspersed among the necessary anatomical descriptions.

The pathology, differential diagnosis, and treatment of the various diseases are very satisfactorily given, and on the whole there is very little to object to. The author figures Sims' semi-prone position drawn from life fairly well as regards the patient, but lying in the middle of a couch in such a way as to render a satisfactory examination impossible. The book is neatly bound, but the plates are often poorly executed. Not a few of them have nothing but their antiquity to recommend them.

The Theory and Practice of Medicine. By FREDERICK T. ROBERTS, M. D., etc., etc. With Illustrations. Fifth American Edition. Philadelphia: P. Blakiston, Son & Co. 1884.

The present edition of Robert's Practice of Medicine is in a single octavo volume of 1000 pages. The work has been revised and enlarged by the incorporation of new material upon many of the subjects treated.

Especial attention has been devoted to the chapters upon diseases of the nervous system.

In one respect this edition is illustrative of the continued and rapid march of study and debate in the sphere with which it occupies itself. The author congratulates himself upon being able to lay before his readers the results of the discussions of the International Medical Congress of 1881, and the readers are already estimating the value and effect of the transactions of its successor, the International Congress at Copenhagen of 1884.

Medical Diagnosis with Special Reference to Practical Medicine. A Guide to the Knowledge and Discrimination of Diseases. By J. M. DACOSTA, M. D., LL. D., etc., etc. Illustrated with Engravings on Wood. Sixth Edition, Revised. Philadelphia: J. B. Lippincott & Co. 1884.

The appearance of the sixth edition of this valuable and popular hand-book of medical diagnosis is coincident with the twentieth anniversary of the first year of its publication. The volume combines those qualities which have been reflected in an eminent degree in the career of the author as at once a successful teacher and practitioner of medicine. It has been translated into German, and issued in Berlin, where its reception has been a flattering one, and a translation into Spanish is projected.

To the American student and practitioner Dr. DaCosta's book requires no further recommendation than the statement that the chapters have been revised, and new matter introduced, with additional wood-cuts, wherever the advances of recent investigations indicated this in order to place the present edition on a level with progress in medical knowledge.

— M. Charcot has been elected a member of the French Academy of Sciences in the place of the late Baron Cloquet.

Medical and Surgical Journal.

THURSDAY, OCTOBER 16, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE FIFTH VOLUME OF THE INDEX CATALOGUE.

THE author of an article on Cataloguing, in the *Library Journal*, commences his essay by a quotation from Thomas Carlyle: "A library without a catalogue is the most strange conceivable object; the worst catalogue that was ever drawn up by the hand of man is preferable to no catalogue at all;" and he closes by saying that the conviction seems to be increasing and deepening that libraries, if they are to fill their full measure of usefulness, must make their treasures accessible to the public. And he pertinently asks whether, if books are worth storing and preserving, with all the additional expense of library maintenance, it is not worth while to put a mere fraction of their whole cost into such a record of them as shall be permanently useful?

The affirmative answer to such a question which the authorities of the Surgeon-General's Office would give would evidently be an emphatic one, enforced by the production of its five magnificent volumes of the Index Catalogue. The fifth volume resembles its predecessors in size and appearance, and alphabetically extends from Flac. to Hearth. It contains in its 1055 pages 15,555 names of authors, representing 5755 volumes and 12,596 pamphlets. It also includes 8069 subject-titles of separate books and pamphlets, and 34,127 titles of articles in periodicals. Eleven pages are needed to contain the recent additions to the list of medical periodicals employed in the Index-Catalogue, most of these additions being newly established journals and recent reports and annuals.

The present volume, like its predecessors, affords an almost childlike pleasure to one who turns its pages with a love for the medical profession and an interest in its literature. One stumbles almost unawares upon the name of Garfield (where he is requested to see Guiteau), and glancing down the long list of writers on these subjects matters are recalled which have already most fortunately begun to slip from the memory. The amenities of literature, if one may venture to speak of them so, are also illustrated in the list, as the following title may show: AUTOPSIA *de Mr. Garfield practicanda por el doctor Longbranch.* [Sic.]

We imagine most men who have occasion to turn to the subject will be surprised to find that the index to articles descriptive of a fœtus in fœtu covers a little over a page and a half. The different editions of Galen, together with the Commentaries and Lives, fill up four pages, and the list will furnish ample entertainment to the bibliographer.

The connection of the Library with the army is brought to mind by the collection of blank forms of the Medical Department of the Army of Great Britain and the Reports on the topography of various forts with more or less familiar names.

As the value of a catalogue as a general work of reference depends upon the character of the library which it represents, it will certainly not detract from the value of the Index Catalogue to recall some observations of Dr. Billings on the comparative merits of the American library with the medical sections of the national libraries of England and France: —

"From a comparison of the catalogue of the medical library of the Surgeon-General's Office with the fasciculi of the catalogue printed by the British Museum in 1881–1882 I have found that on 1140 pages, containing about 34,000 titles, exclusive of cross-references, there were the titles of 657 books and 880 inaugural theses relating to medicine. Taking the corresponding portions of the Washington catalogue it is found that the British Museum has 262 medical books, 372 medical theses, and 118 different editions which are not in the Washington library, while, on the other hand, the Washington library has 285 books, 342 theses, and 88 different editions which are not in the British Museum. There are common to both libraries 277 books and 508 theses. The two libraries are, therefore, nearly equal as regards medical books, exclusive of medical journals, transactions, and reports, in which the Washington library is much the richer."

A similar comparison with the catalogue of the medical section of the Bibliothèque Nationale in Paris shows that the Washington library contains a greater amount of medical literature, and "also covers a wider field, representing better the medical literature of the world. Each library is, as might be expected, richer than its rivals in the literature of its own country, but the French library is comparatively poor in English and German, has almost nothing in American medical literature, while the English library is also poor in American literature, and comparatively weak in German medicine of the present century.

"The two great national libraries of London and Paris are supposed to be the largest collections of printed books in existence. They have been collected during a period of over three hundred years, and have practically had almost unlimited funds and opportunities."

We we may then feel not only that we have in the Index Catalogue an addition to our works of reference which any nation might be proud to have originated, but also that it is the only possible index that could properly represent American medical authors, and that from the character of the Library it comes nearer to being an exhaustive index of all that is valuable in the medical literature of the world than would any similar index and catalogue of any other existing library.

Another writer, in the same number of the *Library*

Journal from which we have already quoted, considers that it will be a chief glory of the nineteenth century that it has organized knowledge, so that the man of the future who will have more to learn will learn it more easily. The isolated facts are fast becoming types. Knowledge increases, but there is no longer confusion, and in this work of organization the librarian has his part. It is for him to classify and catalogue the records of ascertained knowledge, the literature of the whole past, and so to bring the books to readers and readers to books.

In this busy generation, when the hurried man grumbles that "all the time there is" is not enough for him, the librarian makes time for his fellow-mortals by saving it, for a minute saved is a minute gained. And this function of organizing, of indexing, of time-saving, and of thought-saving is associated peculiarly with the librarian of the nineteenth century, and for the medical profession it is associated peculiarly with the librarian of the Library of the Surgeon-General's Office of the United States army.

TWO CASES OF HUMAN ACTINOMYCOSIS.

ATTENTION has been drawn several times in these columns, editorially and otherwise, to a fungoid disease common to various animals — especially cattle — and man, to which the Germans have given the name of actinomycosis. In an editorial, September 11th last, we stated that the disease, although occasionally observed in cattle, had not to our knowledge been found in man in this country.

We now learn from Chicago that Dr. J. B. Murphy of that city has recently operated on two cases of human actinomycosis. One patient was a woman about thirty years of age, who had suffered for a number of months with a hard swelling at the angle of the jaw. The swelling had begun to extend down upon the neck. It was slightly tender, evinced slight fluctuation at one point, and was only to a limited degree movable; it was more or less fixed to the deep tissues. The swelling being opened, a watery, puriform fluid, containing minute bright yellow granules of the size of millet seeds flowed from it. These were at once suspected to be actinomyces, a suspicion promptly confirmed by the microscope. The patient had a number of decayed teeth opposite the point of the swelling on the jaw.

It was afterwards learned that she had, a few weeks before her visit to the doctor, lost by death a pet dog, which had died of starvation from inability to swallow owing to a large swelling connected with its lower jaw.

The operation for the relief of the patient consisted in laying open the swelling freely in all directions and carefully scraping out every particle of tissue that appeared to be abnormal. This and subsequent dressings were done with antiseptic precautions, and the wound healed promptly and completely. The operation seems to have been successful in exterminating the fungus, although too short a time has elapsed to make this positive.

The other patient was a lad, perhaps eighteen years of age, on the right side of whose lower jaw was a swelling of the size of a small walnut. The tumor was opposite a much decayed molar tooth. The patient said the swelling appeared several months before, was quite small at first, and had steadily increased in size. On puncturing the enlargement the yellow granules of the actinomyces were found. The tumor was then freely opened and scraped out. The operation was done only a few days ago, and the wound is not fully healed, but is reported as doing well.

THE SAFETY OF CANNED FOODS.

A SUFFICIENT number of instances of poisoning from the consumption of canned foods continue to be reported from time to time from various parts of the country in the daily press, and at times under cover of a certain degree of medical sanction, to seriously interfere with a very important American industry. We do not doubt that many of these reported cases are greatly exaggerated, and that in a still larger number, whether exaggerated or not, something else than canned food, which is now so readily accused, is really guilty of the effects observed.

It is one thing for a physician to pronounce a case to which he may be summoned one of poisoning, it is quite another and often far more difficult thing to designate the precise article at fault, and before incriminating any individual substance too much care cannot be exercised upon a thorough examination of all the premises —especially where such substance happens to be an article of daily consumption for which, in some parts of the country, it would be difficult if not impossible to provide an equally satisfactory substitute.

There are no food products, whether in the fresh or preserved form, which may not at times be met with in an unwholesome state, but we believe the preserved forms are really less frequently *poisonous* than the so-called fresh forms. Notwithstanding the vigilance of food inspectors in our large cities there can be no doubt that no inconsiderable quantities of "fresh" meats, fruits, and vegetables unfit for consumption escape detection and go into use among some classes of the population. The instances in Europe where large numbers of partakers of fresh meat from diseased animals have been seriously and fatally poisoned thereby are by no means few.

The average annual production of canned foods in the United States is now estimated to be upwards of 500,000,000 of tins, or about ten for every inhabitant of the country. It is not alone a great article of commerce at home and abroad, but, as we have remarked, furnishes a cheap, transportable, and indispensable food-supply in many places and under many circumstances. It is frequently not a question between fresh roast beef or mutton and canned meats, but between these latter and smoked or salted meats; not a question between fresh or canned vegetables and fruits, but between these latter and none at all. We

are not arguing that the canned articles are as nutritive or as toothsome as the fresh, but merely that with the exercise of ordinary care on the part of the consumer the likelihood of being *poisoned* by the former is certainly as small as by the latter. The appearance of the head of the can is generally a pretty safe index to the condition of the contents.

Among other testimony as to the quality and reliability of American canned foods we notice, very recently, that of Gen. J. P. Hawkins, chief of commissary, United States Army, who, during an extended experience of the use of such foods in a military department, never knew of a case of poisoning, nor could he learn of any from inquiry of the medical director.

A striking example of the keeping qualities of canned fish is found in the fact that the American canned salmon, which was awarded the first prize at the Fisheries Exhibition in Berlin, in 1880, was packed in 1875, and had previously been exhibited and took the first prize at the Centennial Exhibition in 1876. The same permanency may be found in many other articles when the can remains sound, and has not been accidentally or purposely tampered with.

Whilst desirous that those engaged in this important national industry should be protected from unjust suspicions and untenable charges it is, as we realize, no less necessary that the more numerous consumers should be protected from fraud or injury, but we imagine the laws of trade are still quite competent for that end without any medical or sanitary crusade.

MEDICAL NOTES.

— Steps have recently been taken in Boston towards the formation of an American society for psychical research, modeled somewhat upon the English society of similar name. At the first meeting Prof. W. F. Barrett, vice-president of the English society, gave an account of the work being done in that country in this line, and mentioned that since the operations of the society began there had been a marked decrease in the activity of the so-called spiritualists in London. The speaker said that in the investigation of cases of "mind-reading" the results showed generally that there was an unconscious physical guidance on the part of the person whose mind was being read, but that there were some cases in which this explanation was not admissible. The committee appointed for organization of a society have held a meeting in furtherance of their work.

— The effect of the embargo upon the importation of rags is likely to be badly felt by the consumers of white paper. The fact that rags are not arriving in this country has already decreased the supply of paper stock, as the mills are not making as much as formerly, and one very prominent paper manufacturer says that 84,000 of the 260,000 tons of rags used in the manufacture of paper in this country are imported, and as this import has ceased the effect upon trade is to put up the price of paper, lessen the working hours in mills, and cause a stagnation in trade unprecedented. Penny papers especially, will probably be affected.

— Dr. Macan, Master in Rotunda Hospital, Dublin, states that during the year sixteen cases of abortion were admitted to the hospital. The treatment was expectant as long as possible, and in none was the vagina plugged, but in case of excessive hæmorrhage before the cervix was sufficiently dilated to allow removal of the ovum the cervix was plugged with a tupelo tent, or dilated with Hegar's instrument, and the ovum removed. When any part of the ovum remained, causing putrid absorption or hæmorrhage, the uterus was well washed out with the corrosive sublimate solution, the curette used, and then the corrosive sublimate again, and in septic cases, in addition, an iodoform suppository was introduced.

— Prof. S. W. Gross, says the *Medical Bulletin* (August), brought a case of gumma of the breast before the class last season, which was interesting, both because of the infrequency of its occurrence, and of its resemblance to malignant disease. Gumma of other parts of the body are met with almost every day in hospital practice, but it is extremely uncommon to find this manifestation of the syphilitic poison on the female breast. The patient, who was twenty-eight years old, and appeared to be in good health, complained of trouble in the left breast. Examination showed a cake-like superficial tumor involving the skin and subcutaneous connective tissue. The skin over the tumor was livid in color, and the nipple was retracted into it. These signs apparently pointed to superficial scirrhus. But from the absence of pain and axillary involvement, as well as the history of a dissolute husband and three miscarriages, Professor Gross concluded that it was a gumma. The woman was put on the mixed specific treatment, and the tumor disappeared in a short time.

— Dr. Koch has recently received a call to the University of Leipsic as successor to the late Professor Cohnheim. It is said that he has declined this honorable call, and resolved to stay in Berlin. It is believed that he will soon be appointed professor of hygiene in Berlin University.

— A correspondent of the *Lancet*, writing of a Roman villa, bath-room, and other ancient remains recently discovered at Lincoln, says that the miners, in clearing away the soil immediately outside the villa, came upon a skull and some human bones, among which he found a tibia presenting a united fracture. He thinks that there is hardly a pathological museum in the United Kingdom which can boast of anything like this specimen of ancient surgery — a united fractured bone of an old Roman who lived, and certainly limped, seventeen or eighteen centuries ago.

CHICAGO.

— The new Presbyterian Hospital has been opened for the reception of patients. One wing only of the contemplated structure is completed; this will accommodate about eighty patients. Owing to lack of endowments of free beds the hospital at present only takes paying patients, but it is expected that before long it

will be possible to receive a number of free patients. The building is very complete in every particular, and in its sanitary arrangements is well-nigh perfect. Steam is used to heat the building, there being one or more steam coils in each room. The fresh air is admitted to each room independently by an opening through the outer wall, so arranged that in entering the room the air must first pass among the steam pipes and be warmed. The exit of foul air is effected through a fireplace and flue with which each room is provided. The laundry, while within the building, is disconnected from every other part of it, and can be reached only by going out of doors. The building is provided with a water elevator.

— The medical colleges have opened with their usual number of students. The Chicago College of Dental Surgery, which, with its present name and plan, is new, inaugurated its first full course as a dental college on the 1st inst. with a class of about forty. This institution was first known as the Chicago Dental Infirmary, and till this year has received as students only such gentlemen as had already received the degree of M. D., and of course it gave no instruction in Anatomy, Physiology, Materia Medica, or Chemistry. But the attendance was so small, and the number of ordinary dental students applying was so great, that it was last spring determined to change the scope of the organization and its name and make it in every sense a dental college. Its quarters at No. 6 Washington Street are ample, and its clinical material is greater than is necessary. Drs. Belfield, McArthur, and Copeland have been chosen to teach, respectively, Physiology, Chemistry, and Anatomy.

MEDICO-LEGAL NOTE.

— Dr. Nobiling, of Munich, has, according to the *British Medical Journal* (June 14th), recently described in the *Aerztliches Intelligenzblatt* the necropsies which he made a year or two since on the bodies of two suicides by hanging. The first case was that of a young man, aged twenty-four, short, thin, and sickly, who destroyed himself after a disappointment in love. He tied the two ends of a large cotton handkerchief, folded diagonally and not twisted into the form of a cord, and fixed them on to the latch of a door, put his head through the loop of the handkerchief, and then drew up his knees. The latch was only three feet seven inches from the ground, and the man was found quite dead, with his knees bent to a right angle, his shins almost touching the floor, against which the toes actually rested. The weight of his head and shoulders pressed the front of his neck downwards against the handkerchief, which did not touch the back of the neck at all. As the handkerchief had been folded very broad, no line of constriction was found on the front of the neck. The hyoid bone, with the root of the tongue and larynx, had been forcibly and firmly drawn upwards and backwards against the posterior wall of the pharynx, so that all access of air to the glottis was excluded. There were small points of subconjunctival, subpleural, and subpericardial hæmorrhage. What appeared most remarkable to Dr. Nobiling was that the otherwise healthy endocardium of all the chambers of the heart was thickly spotted with small points of extravasated blood. The lungs were very œdematous. There were evidences of old pachymeningitis. The second case was that of a very corpulent man, aged forty, subject to melancholia, who had mounted on a stool, attached the ends of a stout cord, made of a piece of vine branch strengthened by hempen twine, to the cross-piece of a high window, put his head through the loop, and kicked the stool from under him. He was found quite dead, with the tips of his toes far from the ground, and his thick neck completely constricted above the thyroid cartilage by the cord, which made a deep mark round the neck. So deep was this constriction that the muscles attached to the hyoid bone, the sterno-mastoids, and the superficial layer of the muscles at the back of the neck were all very deeply indented, and hæmorrhage had occurred into their substance. There was also much extravasation of blood into the connective tissue within the sheath of the great vessels of the neck, but the common carotids and the internal jugular vessels were uninjured. The larynx was pressed upwards and backwards against the back of the pharynx, the mucous membranes of the larynx, trachea, and bronchi were deeply congested, and there were circumscribed hæmorrhages under the right vocal cord, the cellular tissue beneath the pleura on both sides, and in the pulmonary tissue. Aortic stenosis, great hypertrophy of the heart, nutmeg liver, contracted kidneys, chronic gastro-adenitis, and colloid degeneration of the pancreas also existed.

Miscellany.

MR. J. NETTEN RADCLIFFE.

MR. J. NETTEN RADCLIFFE, lately deceased, was unquestionably one of the ablest of the staff of men attached to the Medical Department of the English Privy Council and of the Local Government Board. The annual reports of those bodies are the best monument to his learning, zeal, and industry in contributing to the progress of State Medicine. His former chief, Mr. John Simon, writes to the *Lancet* in regard to the character of Mr. Radcliffe's work as follows: —

"Among reports which he made on the subject of particular local outbreaks of disease investigated by him there are especially three which I count classical. (1.) The Report on the very remarkable Outbreak of Cholera at Theydon-Bois, near Epping, in 1865. (2.) The Report on the East London Cholera Epidemic of 1866, and its relation to the use of the East London Company's Supply of Water. (3.) The Report on the terrible Epidemic of Enteric Fever which prevailed in and about Marylebone in 1873, in consequence of a Dairy Company's Distribution of Infected Milk. These Reports ought to be familiarly known to every officer of health, not only for the tremendous significance of the lessons which they teach, but as examples to be studied and remembered of the minutely cautious and complete way in which local epidemics require to be investigated by any one who aspires to advise on them.

Equally classical in the literature of preventive medicine, though in another direction than the above, are the expositions which he made in matters of epidemiological history, more particularly in 1866 and 1875, with reference to the successive steps by which cholera had advanced from India and had been diffused to various countries of Europe; and in various late years with reference to the diffusions of Levantine plague. His acquaintance with the 'time and place' relations of epidemic and endemic diseases was unusually large and accurate, particularly in respect of cholera and plague, and of the therewith connected questions of traffic between places and countries. It was, I believe, quite unique; it was like the familiar knowledge which a Charing-cross policeman is supposed to have of the omnibuses which pass his beat; and in the distribution of the work of the Medical Department I used always to look to him as a specialist in that branch of information.

"In 1875, when, as you may remember, there had been considerable cholera alarms in Europe for the last year or two, and when an International Conference on Cholera had been held at Vienna, I found it desirable to reëxamine our scientific stand-point in relation to the opinions of other countries; and the occasion was also taken for Radcliffe to extend his cholera paper of 1866 into a report for the whole decennial period. For the guidance of European opinion on the question of Red Sea quarantine, and other such questions, the mass of evidence given in that report with regard to the many ways by which cholera, so often as it grows in India, tends to reach Europe, is, in my opinion, the most instructive document in existence; and the man who can resist that kind of evidence must be either an idiot or a quarantine employee. To the ordinary medical reader it might be too laborious to study the paper, but as a *pièce de résistance* for the English Government when it has to confer with other governments about their quarantine proposals the report is simply invaluable, and worth even the immense labor which Radcliffe bestowed on its compilation."

SANITARY CONDITION OF NICE AND THE RIVIERA.

THE following "declaration of the consuls residing at Nice, Cannes, and Menton," was made public at Nice the 16th of last September: —

Firstly. That the town of Nice and the neighboring winter resorts on the Mediterranean coast, owing to the excellence of their climate, and the careful precautions for the preservation of health, promptly and effectually taken by the municipal authorities, have entirely escaped the epidemic, and that the public health has never been in a more perfect condition.

Secondly. That the quarantine which had been enforced as a preventative measure at the western extremity of Nice, in the Var district, has ceased to exist since the 6th instant, which allows of travelers entering the town without having to undergo any formalities or being subject to any delay.

We therefore feel it a duty and a pleasure to declare publicly and formally, with a view to the general interest, and that our countrymen may be accurately informed of the real sanitary condition of these sunny regions, that the foreign colony who, on the return of the cold season, are wont to take up their winter quarters in these parts may, as usual, with safety come to Nice, Cannes, Menton, and, indeed, anywhere along the Mediterranean shore from Hyeres to San Remo. The consuls have accordingly signed the present declaration.

The above will have an interest for the medical advisers of that large class of our countrymen whose health or pleasure annually attracts them to these towns in Southern France or along the Italian Riviera. The drainage in most of these places is justly suspected, and we hope may not betray the confidence reposed by the foreign consuls in the good features of these localities.

ABSTRACT OF THE REPORT OF THE COMMISSIONER OF EDUCATION FOR 1882-83.

THE thirteenth annual Report of the Commissioner of Education, just issued, is fully equal to its predecessors in point of interest, in the importance of subjects discussed, their methodical arrangement and treatment, while the information presented is of much more recent date than that usually given in reports whose information is collected from such a vast territory and through so many instrumentalities, covering, as it does, the year closing June 30, 1883. In this respect the report under review has made a decided gain over its predecessors, made possible, we are informed, by the fact that a larger number than usual of educational systems and institutions have been able to bring their reports up to date.

Little space is given in the report to a statement of the general work of the office aside from the summary of educational data which is prepared annually, as anything like a full statement of such general work would require more space than the Commissioner has at his disposal.

The communications sent out numbered 30,745, and those received 67,875. The documents distributed numbered 323,592, and were usually mailed in separate packages. One document was asked for by as many as ten thousand persons. This distribution of documents has its influence upon many educational methods and appliances. The teachers' institutes have been much more freely supplied than before. Circulars and bulletins were sent to 406 institutes held in twenty-three different States. Seventy-eight of these teachers' gatherings in a single State were furnished these publications.

The following circulars of information have been printed and distributed since the enumeration in the previous report: No. 1, 1882. The Inception, Organization, and Management of Training Schools for Nurses. 28 pages. No. 2, 1882. Proceedings of the Department of Superintendence of the National Educational Association at its meeting at Washington, March 21–23, 1882. 112 pages. No. 3, 1882. The University of Bonn. 67 pages. No. 4, 1882. Industrial Art in Schools, by Charles G. Leland, of Philadelphia. 37 pages. No. 5, 1882. Maternal Schools in France. 14 pages. No. 6, 1882. Technical Instruction in France. 63 pages. No. 1, 1883. Legal Provisions Respecting the Examination and Licensing of Teachers. 46 pages. No. 2, 1883. Co-education of the Sexes in the Public Schools of the United States. 30 pages. No. 3, 1883. Proceedings of the Depart-

ment of Superintendence of the National Educational Association at its meeting at Washington, February 20–22, 1883. 81 pages. The following bulletins have also been issued: Instruction in Morals and Civil Government. 4 pages. National Pedagogic Congress of Spain. 4 pages. Natural Science in Secondary Schools. 9 pages. High Schools for Girls in Sweden. 6 pages. Comparative Statistics of Elementary, Secondary, and Superior Education in Sixty Principal Countries. Sheet. Planting Trees in School Grounds. 8 pages. In addition to these publications a special report of three hundred and nineteen pages on Industrial Education in the United States was prepared and printed in compliance with a resolution of the Senate. The number of copies of each circular or bulletin issued has been increased to supply the correspondents of the office, and several of those most in demand have been reprinted.

The American correspondents of the office at the head of systems or institutions of education furnishing the information contained in the report numbered 10,128, an increase for the year of 1354, and since 1872 of more than 7500. This system of voluntary statistical information, depending on co-laborers so widely scattered, is believed to be the most extensive of its kind in existence, and it is constantly improving in completeness and exactness. The blanks sent out by the office to its 10,000 correspondents and gratuitously filled and returned by them form the basis for the twenty-five tables presented in the appendix. The only return the office is able to make its friends for all this labor is to send them its publications, and hitherto the number allowed the office by Congress has not been sufficient to supply them all.

A CASE OF SCARLET FEVER IN A CANARY.

A supposed case of scarlet fever in a canary bird is reported in the *British Medical Journal* by Dr. F. Ogston as follows: —

"A few months ago, while attending a family in which scarlet fever had attacked two children, my attention was called to a cage containing four young canaries. I remarked that they seemed ill, as they were sitting moping on their perches, with their feathers ruffled up. The mother of the children said to me, 'Doctor, I think they have gotten the fever. The grandmother (who had undertaken the nursing of the children) gave them some bread which the children had been eating.' The children were then desquamating freely.

"Two days afterwards, when seeing the children, I found the canaries quite well and lively, all but one, which drooped more than before, and now could hardly stand. On examining the bird its skin, under the feathers, was of a bright scarlet color, unlike that of the others, which was of a yellow color, like old parchment. It died the following day, after making efforts to swallow as if its throat had been painful and swollen.

"On inquiring why this one should have suffered so much, and the others so slightly, I was told that it had eaten greedily of the bread left by the children, which the others had hardly touched, and that it had pecked away some of the loose epidermis from the lips of one of the children.

"It certainly seemed to me that the bird had scarlet fever, and it at least should give us the caution that our domestic pets may not only spread this disease by conveying the infected epidermal scales on their fur or feathers, but also by taking infection from their owners, and directly infecting individuals of the human species in their turn."

DYSTOCIA FROM COILING OF THE CORD ABOUT THE NECK OF THE FŒTUS.

Dr. Rachel in the September number of the American *Journal of Obstetrics*, details five cases of this complication occurring in his own practice, and gives some reflections upon its occurrence and treatment. He cites a report on the subject made to the Obstetrical Society of Edinburgh, January, 1883, giving the means for diagnosis as follows: —

"(1.) Retraction of the fœtal head during the pains, with sufficient uterine action and a roomy pelvis.

"(2.) Gradual cessation or long abeyance of the pains; and

"(3) Insufficient head flexion, followed by over-rotation of the occiput; all pointed to coiling of the cord round the child's neck. The second factor above stated he believed to be the most important.

"For diagnosis of this condition when the head was in the pelvis, he held that it could be made out by digital examination when the pelvis was roomy. If he suspected its occurrence in the first stage he would employ sedatives; in the second stage he would hasten the labor in the usual way, or cut the cord with a pair of probe-pointed scissors, and then employ forceps."

The writer joins issue with the statement of the first point; it should be just the reverse, for the sentence as it stands applies to the normal conditions of labor, the head in normal labor, it is almost superfluous to mention, being retracted somewhat during a pain while it descends on its cessation by the force of gravity. This advance of the child during the pain and retraction when the pain ceased was noticeable in every one of Dr. Rachel's five cases, and is in accord with Cazeaux's observations.

Regarding the degree of embarrassment from a coiled cord, Dr. Rachel says that his measurements of the circumference of the neck in every child he has delivered for the past year give as the lowest figure six inches and the highest a little over eight inches. He at the same time measured the distance from the umbilicus to the side of the neck, and found that it averages seven inches and a half, the lowest figure being six and a half and the highest a little over eight and a half inches. Taking the lowest figures found, a threefold circle — which in reality requires, in face presentations, only two and a half circumferences —

Would give	15 inches.
Length from umbilicus to side of neck . .	6½ inches.
	21½ inches.

The remaining portion of the cord from the neck to the placenta is not taken in account, and be it ever so short, it would still add several inches to the calculated figure. He thinks that even the tightest constriction around the neck, coupled with the strongest traction short of rupture of the cord, would be unable to reduce the number of inches by one half, that is, to eleven inches. In one of the writer's cases he gives the following figures: —

From umbilicus to neck	8 inches.
Two full coils	15 inches.
Together	23 inches.

which leaves for the length of cord from neck to placenta: $29\frac{1}{2}—23=6\frac{1}{2}$ inches. This would about correspond to the distance from the vulva to the placenta, which was situated anteriorly to the left of the median line.

In another case the figures were:

From umbilicus to neck	$6\frac{1}{2}$ inches.
One full circle	6 inches.
Together	$12\frac{1}{2}$ inches.

which would leave for the length of cord from neck to placenta: $16\frac{3}{4}—12\frac{1}{2}=4\frac{1}{4}$ inches.

The shortest cord ever measured (Cazeaux) was two inches long, and it was torn just before the expulsion of the child; but, of course, in this case the cord went directly from the umbilicus to the placenta. The shortest cord measured by the writer was ten inches, and there being no coil about the neck it gave little convenience during labor.

The writer's conclusions are summarized as follows:

Diagnosis. 1. Descent of the head during the pains and retraction during the intervals.

2. Insufficient head flexion and over-rotation of the occiput.

3. Variability of the position of the head within narrow limits.

4. Distressing pain at the seat of the placenta.

5. Discharge of some blood immediately after each pain.

If rigid perinæum, dorsal displacement of an arm, or head and arm presentation can be excluded the first symptom, especially when combined with some or all others given, point to true or accidental shortening of the cord.

Treatment. 1. Anæsthetization of the patient.

2. Extraction of the head by the forceps and division of the cord to allow the delivery of the body. Or, in extreme cases,

3. Division of the cord within the vagina, followed by the application of the forceps.

The early division of the cord may be urgently required to save the life of the child, as is illustrated by Dr. Lusk's case, and by a case cited by Cazeaux, where it was delayed two hours after the birth of the head. It also militates against two other formidable accidents, namely, inversion of the uterus and flooding.

INTRA-UTERINE THERAPEUTICS.

DR. THOMAS MORE MADDEN contributes an article on the above subject to the *Medical Press* (September 24th) emphasizing the importance of this method of treatment. His statement will, perhaps, cause some surprise that among 3800 patients under observation in the gynæcological department of the Mater Misericordiæ Hospital during the last six years, including almost every variety of disease peculiar to women, intra-uterine exploration or treatment was found necessary in about thirty per cent., and was resorted to in them when not specially contra-indicated by pregnancy or pelvic cellulitis.

The importance of adequate dilatation is emphasized, and laminaria bougies are considered, on the whole, the best agent for this purpose. Before making applications to the endometrium that surface must be prepared (if not found at the period of post-menstrual denudation) by scraping either by a dull wire curette, or, as the writer prefers, by his intra-uterine scoop, which he considers more effective in removing the granular, softened, or diseased mucous membrane so as to expose the true inner surface of the uterus to the medicaments. The local depletion of congested or hypertrophied parts, especially in cases of endometritis, is also of value.

The most active of all the various agents employed for intra-uterine medication is fuming nitric acid, introduced into modern gynæcological practice by Dr. Kidd in the Coombe Hospital, and subsequently employed by Dr. Atthill in the Rotunda, and by Dr. Madden in the Mater Misericordiæ Hospital, Dublin, long before it was thus applied elsewhere. For the intra-uterine use of nitric acid it is necessary that the os uteri should be dilated and exposed to view, the vaginal wall properly protected from injury with the acid, and the uterine wall drawn down to the vulva. For this purpose he has designed and uses a uterine tenaculum, shown, which can be set at any angle, and instantly released from its firm hold on the cervix by merely turning the screw set in the handle. In this way the uterus may be easily swabbed out with strong nitric acid, the whole charge of which is thus expended on the endo-uterine surface so as to avoid the risk of injuring the vaginal walls or external parts, although, as an additional precaution, these should be well smeared over with vaseline beforehand. Immediately after the application the uterus should be thoroughly washed out until no trace of acid is discoverable in the returning water; and finally, if any pain is complained of, a morphia suppository should be introduced. When thus employed nitric acid may generally be as safely and effectively used in those cases of intra-uterine disease in which its application is really called for, and to which it should be carefully restricted.

Solid nitrate of silver was formerly in some vogue as an intra-uterine application, a small bit of it being occasionally introduced and left in utero in cases of subinvolution, and even endometritis, even without any preliminary dilatation of the os internum. This practice, however, is liable to give rise to local inflammation or metro-peritonitis. Iodoform, in suppositories containing from seven to ten grains, will be found useful, after more active treatment, in some instances of congestive hypertrophy of the uterus. Carbolic acid, and above all iodized phenol, as well as the various other preparations of iodine, are, however, probably the most generally useful of all intra-uterine applications, and of these Churchill's tincture, or a solution of iodine in glycerine of the same strength as the ordinary tincture, may be locally applied freely with advantage in many cases of congestive hypertrophy, and also in some instances of intra-uterine tumors in which operative treatment will not be submitted to or is not advisable. Of the injection of tincture of iodine through the undilated canal, which has been recently again recommended for the same purpose, Dr. More Madden speaks with some caution from his own experience of its use.

Regarding the removal of intra-uterine growths the writer is quite enthusiastic. In the past few years he has removed such tumors from the uterus in forty-two cases. Of these four were intra-mural, eighteen were

submucous fibroids, and twenty were either pedunculated tumors or intra-uterine polypi. In one case six of these tumors were removed from the uterus at one operation, and in another instance two large tumors which had, apparently, coalesced from opposite sides of the womb were taken away. And finally in three of these cases the patients died, and in thirty-nine they recovered.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 4, 1884.

Deaths reported 2546 (no reports from Chicago, Buffalo, and Pittsburg): under five years of age, 1104; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 631, diarrhœal diseases 307, consumption 294, lung diseases 184, diphtheria and croup 113, typhoid fever 79, malarial fevers 42, whooping-cough 38, scarlet fever 23, cerebro-spinal meningitis 15, erysipelas seven, measles six, puerperal fever one. From *malarial fevers*, New York 17, St. Louis 11, Brooklyn seven, Nashville three, Charleston two, Cincinnati and West Springfield one each. From *whooping-cough*, New York 19, Brooklyn and Boston six each, Philadelphia, Baltimore, District of Columbia, Nashville, Cambridge, Brockton, and Milbury one each. From *scarlet fever*, Boston five, Philadelphia three, Baltimore, St. Louis, Providence, and Woburn two each, Brooklyn, Cincinnati, District of Columbia, Lowell, Cambridge, Lawrence, and Newton one each. From *cerebro-spinal meningitis*, Philadelphia four, New York and Lowell two each, Boston, Baltimore, Fall River, Lawrence, Holyoke, Woburn, and Milbury one each. From *erysipelas* Philadelphia three, New York two, Providence one. From *measles*, New York five, Philadelphia one.

Two cases of small-pox were reported in St. Louis; typhoid fever 59, scarlet fever 62, diphtheria 31, and measles one in Boston.

In 109 cities and towns of Massachusetts, with an estimated population of 1,412,907 (estimated population of the State 1,955,104), the total death-rate for the week was 18.58 against 23.01 and 20.64 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending September 20th, the death-rate was 21.0. Deaths reported 3518: infants under one year of age 1051; acute diseases of the respiratory organs (London) 159, diarrhœal diseases 413, fever 91, scarlet fever 82, whooping-cough 52, measles 41, diphtheria 29, small-pox (London six, Sheffield one) seven. The death-rates ranged from 14.9 in Portsmouth to 29.9 in Leicester; Birmingham 25.4; Blackburn 28.3; Bradford 21.9; Leeds 21.8; Liverpool 26.8; London 17.1; Manchester 23.4; Nottingham 22.1; Sheffield 27.6; Sunderland 25.8. In Edinburgh 19.2; Glasgow 23.7; Dublin 26.6.

For the week ending September 20th, in the Swiss cities, there were 29 deaths from consumption, diarrhœal diseases 20, lung diseases 16, typhoid fever five, diphtheria and croup three, whooping-cough two, small-pox, scarlet fever, and erysipelas each one. The death-rates were, at Geneva 12.2; Zurich 9.8; Basle 10.8; Berne 16.7.

The meteorological record for the week ending October 4th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date. Sept.–Oct., 1884.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY FROM OCTOBER 4, 1884, TO OCTOBER 10, 1884.

CLEMENTS, B. A., major and surgeon. In addition to present duties to take charge of the office of the Medical Director of the Department during the temporary absence of that officer. Paragraph 1, S. O. 195, Department of Missouri, September 29, 1884.

HAPPERSETT, JOHN C. G., major and surgeon. Will be relieved from duty in Department of the East, and ordered for duty at Willet's Point, New York.

WOODRUFF, EZRA, captain and assistant surgeon. Granted leave of absence for four months. S. O. 235, A. G. O., October 7, 1884.

CRONKHITE, HENRY M., captain and assistant surgeon. Assigned to duty as post surgeon, Fort Reno, Ind. Ter. S. O. 197, Department of Missouri, October 2, 1884.

CRAMPTON, L. W., captain and assistant surgeon. Granted leave of absence for one month and ten days. S. O. 60, headquarters Division of the Atlantic, October 2, 1884.

POWELL, J. L., captain and assistant surgeon. Granted leave of absence for one month on surgeon's certificate of disability.

SPENCER, WM. G., captain and assistant surgeon. Granted leave of absence for one month. S. O. 204, headquarters Department of the East, October 8, 1884.

MCCREERY, GEO., first lieutenant and assistant surgeon. Assigned to duty at Fort Meade, D. T. S. O. 115, headquarters Department of Dakota, October 6, 1884.

TAYLOR, A. W., first lieutenant and assistant surgeon. Assigned to duty at Fort Omaha, Neb. Paragraph 3, S. O. 87, headquarters Department of the Platte, October 3, 1884.

BLACK, C. S., first lieutenant and assistant surgeon. Granted leave of absence for fifteen days to take effect this date. Paragraph 3, S. O. 131, Department of Texas, September 29, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING OCTOBER 11, 1884.

LIPPINCOTT, G. C., passed assistant surgeon. Granted sick leave. October 4, 1884.

WHITING, ROBERT, passed assistant surgeon. To the Naval Hospital, New York. October 6, 1884.

BROWN, S. A., passed assistant surgeon. Resignation accepted. October 7, 1884.

BRUSH, GEORGE R., surgeon. Detached from the Vandalia and placed on waiting orders. October 8, 1884.

CRAIG, THOS. C., passed assistant surgeon. Detached from the Vandalia and placed on waiting orders. October 8, 1884.

AYERS, JOS. G. Leave of absence for one month. October 10, 1884.

OBERLY, A. S, surgeon. To the Naval Hospital, Portsmouth, N. H. October 10, 1884.

CLEBORNE, C. J., medical inspector. Detached from duty at Portsmouth, N. H., and placed on waiting orders. October 10, 1884.

STEELE, JNO. W., passed assistant surgeon. Detached from the Brooklyn and placed on waiting orders. October 10, 1884.

BOYD, JNO. C., passed assistant surgeon. To duty at Navy Yard, Washington, D. C. October 10, 1884.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, JULY 1, 1884, TO SEPTEMBER 30, 1884.

BAILHACHE, P. H., surgeon. To proceed to Delaware Breakwater Quarantine Station as inspector. September 10, 1884.

To investigate reported pollution of Potomac River water supply. September 20, 1884.

MILLER, T. W., surgeon. Granted leave of absence for fourteen days. July 10, 1884.

Detailed as president Board of Examiners. September 2, 1884.

WYMAN, WALTER, surgeon. Detailed as member Board of Examiners. September 2, 1884.

LONG, W. H., surgeon. Granted leave of absence for twenty days. July 30, 1884.

PURVIANCE, GEORGE, surgeon. Detailed as recorder Board of Examiners. September 2, 1884.

STONER, G. W., passed assistant surgeon. To proceed to Lewes, Del. (Delaware Breakwater), as inspector. July 25, 1884.

To act as quarantine officer at Delaware Breakwater. July 31, 1884.

FISHER, J. C., passed assistant surgeon. Granted leave of absence for thirty days. August 21, 1884.

GOLDSBOROUGH, C. B., passed assistant surgeon. Granted leave of absence for thirty days. July 12, 1884. Leave of absence extended thirty days on surgeon's certificate of disability. August 11, 1884. Leave of absence extended thirty days without pay. September 11, 1884.

HEATH, W. H., passed assistant surgeon. Granted leave of absence for thirty days. September 8, 1884.

GUITÉRAS, JOHN, passed assistant surgeon. Granted leave of absence for thirty days. September 24, 1884.

BANKS, C. E., passed assistant surgeon. Granted leave of absence for thirty days. August 27, 1884.

BENNETT, P. H., assistant surgeon. To proceed to Buffalo, N. Y., for temporary duty. September 19, 1884.

GLENNAN, A. H., assistant surgeon. To proceed to Mobile, Ala., for temporary duty. July 7, 1884.

RESIGNATION.

FISHER, J. C., passed assistant surgeon. Resignation accepted by the Secretary of the Treasury, to take effect September 30, 1884. August 21, 1884.

DIED, — At Shelburne, Mass., October 4, 1884, Charles Morris Duncan, M. D., M. M. S. S, aged seventy-six years.

Original Articles.

WEIGHT AS AN INDICATION OF THE CHARACTER OF RISKS FOR LIFE INSURANCE.[1]

BY JOEL SEAVERNS, M. D., OF ROXBURY.

THE Royal Arcanum, a beneficiary organization, which has to-day nearly 50,000 members, in all the States of the Union except the Gulf States, and has paid out since January, 1868, over $3,000,000 in life insurance to the families of its deceased members, has among its records up to March 1, 1884, details of the deaths of 974 men between the ages of twenty-one and sixty. These details include, together with the family and personal history of the individuals, statements of their age, occupation, height, weight, rate of pulse and respiration, results of auscultation and percussion of chest, and an examination of the renal secretion, certified to by a medical examiner on their entrance to the Society. At their deaths is added to these facts a certificate signed by the attending physician, giving the duration of the fatal illness, its supposed cause, symptoms, and diagnosis, and the results of the autopsy if one is held.

From this store-house of facts, to which I have been allowed access, many important generalizations may be drawn, bearing upon the selection of lives for life insurance. On only one point to-day, that of weight, and its relation to height, I address you.

You are all aware that for life insurance purposes tables have been constructed giving what is considered the natural standard of weight and height. These tables vary but little in different works on this subject, and that which I shall refer to to-day is embodied in the tables on page 386.

The general directions in companies and societies are that while this proportion is the natural one, a variation of twenty per cent. from it in either direction is not to be deemed a cause for rejection. I am inclined to think that as regards the candidates of light weights (those whose weight is below the standard) less latitude should be allowed, and that a variation of even fifteen per cent. in that direction makes the risk hazardous, and that every applicant whose weight is materially below the standard, even ten to fifteen per cent., should be examined with the utmost care, not only to ascertain whether he has actually at that time any *disease*, but whether there may not be some tendency to disease, some weakened, malformed, or imperfectly developed organ, some functional ill performance of the vital processes of digestion, assimilation, or absorption, which if conditions of life should be unfavorable may prove to be the starting point of constitutional disease.

Men are thin for various reasons: some because in their families is a hereditary tendency to be so; some because they have diseased lungs, heart, or digestive organs; some because they have recently been sick or are over-worked, or have too much anxiety and care, or are ill fed; and the examiner should in each instance gravely scrutinize the problem to see what is in *that* case the special cause of this effect, and whether it may not be a cause that threatens to shorten a man's years, or at least an influence, which shows in what direction to look for future illness or death. And thus, for instance, if there has been in the family history any case of hereditary disease, — especially of constitutional wasting disease, — or if there has been in the personal history any of those symptoms or diseases that so often precede tuberculosis, such as impaired digestion, hæmorrhoidal tumors, fistulas, etc., and the applicant is at what may be called the consumptive age (under thirty-five or forty years old), he should be unhesitatingly *rejected*, as one who is not likely to live out his estimated expectancy.

With reference to this question I have made an examination of these 974 deaths with this showing: Amongst them were 138 men, who at their admission were fifteen per cent. or more below the standard of weight that we have referred to, and of this 138 eighty-five, or about sixty-two per cent., died of chronic disease, seven from accident or suicide, and only forty-six of acute diseases. Of the eighty-five chronic cases, forty-two were from phthisis, tabes mesenterica, or pulmonary hæmorrhage; seven died of organic disease of the brain or medulla, caries of the vertebræ, progressive muscular atrophy, and general paralysis of the insane; six died from cancer; three from diseases of the liver; nine from urinary diseases (five of Bright's disease, two from diabetes mellitus, one from chronic cystitis and abscess of the kidneys, and one of stone in the bladder); five died of organic disease of the heart; one of pernicious anæmia, and one of "general debility." The acute cases included pneumonia and other lung diseases, typhoid fever, and diseases of the digestive organs.

Ninety-one of these men were under forty years of age when admitted, thirty between forty and fifty, and only seventeen more than fifty.

Twenty-two died in less than a year after admission, twenty-nine in between one and two years, thirty-four in between two and three years, thirty-six in between three and four years, thirteen in between four and five years, and but four lived more than five years. The average duration of their membership was about thirty-one months.

Now of these 138 only thirty-three were twenty per cent. below the normal standard, 105 being in that border-land between what is usually considered safe and the line which I claim should be the dividing boundary; twenty-four of the thirty-three lightest ones were cases of chronic disease, thirteen being of phthisis.

Only nine were more than twenty-five per cent. below the standard, and all but two of these died of some organic disease, four from phthisis.

This is, in brief, a summary of the deaths of such of the 974 deceased members as were at the time of their admission fifteen per cent. or more *below* the usual weight, and in order that the results may be shown more clearly to you I have drawn them up in tabular form and printed them, that you may at a single glance see how extraordinarily prone to constitutional disease are such candidates. And I feel confident that the table will prove conclusively that such risks ought not to be accepted in life insurance.

Let us now reverse the picture. Among the 974 deaths were those of 122 members who, on joining the Society, were fifteen per cent. or more *above* the weight assumed to be the normal one.

Of these, leaving out fifteen who died of casualties and five who committed suicide, fifty-six, or about forty-

[1] Read before the Massachusetts Medical Society, June 11, 1884, and recommended for publication.

six per cent., died of some lingering illness, and forty-six of acute attacks.

Twenty-six of the deaths were from disease of the brain or spine (twelve being apoplectic); twenty-four from disease of the heart and circulatory system; sixteen from disease of the kidneys and urinary organs (including twelve of Bright's disease); eleven died from diseases of the abdominal organs; fourteen from zymotic diseases; and seven of acute lung diseases. None died of phthisis, and but three of cancer.

It will be remembered that among the *light* weights ninety out of 138 were under forty years of age on joining, but of these *now* under consideration eighty-three of 122 were *over* forty when admitted, forty-three between fifty and sixty, and only four were less than thirty. Their average age was forty-five years.

Twenty-eight died in less than a year after being taken into the Society; thirty-six in between one and two years; twenty-four in between two and three years; seventeen in between three and four years; twelve in between four and five years; and but five lived more than five years. The average duration of their membership was twenty-seven months.

Now in that border-land, as I have called it, between fifteen per cent. and twenty per cent., among the heavy weights there were but forty-seven who have died (whilst there were, it will be remembered, 105 of the light weights), and of this forty-seven twenty died of cerebral or cardiac affections, eleven from casualties and suicides, eight of zymotic and intestinal disease, six from urinary complications, and two from cancer.

It is not until we get beyond the twenty per cent. line in this class that the principal part of the deaths occur, namely, seventy-five, thirty being from brain or heart disorder. Going still farther, it appears that there were forty-nine whose weight was more than *twenty-five per cent.* in excess of the standard, some of these exceeding forty per cent., and a few reaching even fifty per cent. beyond that rate. But of these excessive weights the cause of death was hardly what might have been anticipated, for there is no increased preponderance of brain or heart disease, the figures of

those over twenty-five per cent. being twenty-two in those diseases, six of diseases of the kidneys, six casualties, nine zymotic and digestive diseases, and all other causes six, the character of the changes which proved fatal seeming to be rather those peculiar to senile degeneration than those of fatty changes, it being borne in mind that more than a third of the men of excessive weight were over fifty years old, and more than two thirds over forty.

If, in summing up, the results of the two classes of cases be compared, it is to be noticed, first, that the *number* of those dying who are deficient in weight is greater than of those who have a superabundance of adipose tissue. This point cannot be accurately tested, of course, without knowing how many of each class have been admitted to the order, and this could only be done by too great labor, but I am satisfied that the number of those admitted who are fifteen per cent. or more *above* weight is greatly in excess of those fifteen per cent. or more *below* the standard, while the deaths, as has just been said, are more frequent among the latter.

It further appears, too, that as to the character of diseases to which they succumb there are more of those light in weight who die of chronic constitutional diseases, and more of those heavy in weight who die of accident, zymotic or acute diseases, though many of the latter fall victims to diseases of the arteries and the heart. *Sudden* deaths also are much more frequent with the heavy weights.

Still farther, it seems that the deaths are not so frequent of the heavy men who are but little (fifteen to twenty per cent.) *above* the standard as among the light weights who are fifteen to twenty per cent. below.

The conclusion which I have therefore reached from these observations is, very briefly, this: that for life insurance purposes men whose weight is above that laid down in the usual tables are better risks than those whose weight is less; that among the latter (light weights) the usual variation of twenty per cent., which is assumed to be within safe limits, is not safe, and that if we accept men, especially young men, whose weight is fifteen per cent. below the standard, we are approaching dangerous standing ground, and inviting, as it were, deaths from phthisis and wasting diseases; and when we reflect how great is the mortality from phthisis in all insurance organizations we cannot too strongly emphasize the necessity of constant vigilance in this direction, and of not only exploring most carefully the chest of such men, but also of taking into account all these other features which I think often precede the changes in lung tissue discernible by the ear, and may be observed at what may be called the pre-tuberculous stage.

With the heavy weights the case is different; free from danger of phthisis, we must, to be sure, take the greatest care to see that the heart and kidneys are healthy, and that the family history does not point to cerebral disease. With these points well guarded I am satisfied that an excess of twenty-five per cent. in weight is not dangerous in men who have not injured or are not injuring themselves by alcohol.

It may be said very truly that much in both classes must depend on the family history and inborn tendencies to disease of the parties, and that in this résumé I have not dwelt on this subject, but in *most* of the cases here cited the family history did *not* indicate danger from constitutional disease, because the greater number of such applicants as have anything unfavorable in those respects are rejected when they apply. These tables, therefore, have been made up largely and almost entirely of men whose deficiency or excess of weight was the *only* unfavorable feature at the time of their being accepted, this feature not having been then regarded as sufficiently important to have a determining effect on the question of rejection.

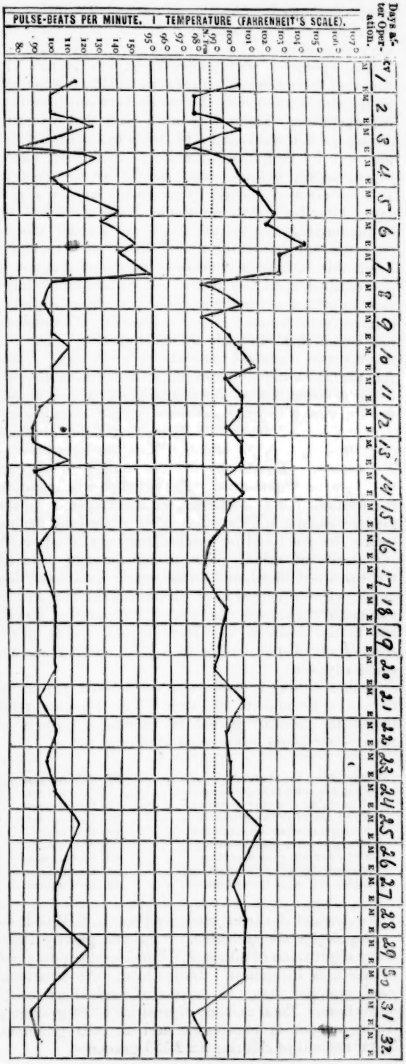
EXTIRPATION OF A RETRO-RENAL SARCOMA BY ABDOMINAL SECTION.[1]

BY JAMES R. CHADWICK, M. D., BOSTON.

MRS. A. M. E., aged fifty-two, a widow, had had two children and five miscarriages. For twenty years she had occasionally had functional urinary disturbances. Since the birth of the last child, ten years ago, she had been in fair health except that for a year she had been having night sweats, chills, and been losing flesh and strength. In January, 1884, she had a very severe backache, attributed to cold, which was finally relieved by Dr. C. E. Stedman, who recognized no special cause until the fullness of her abdomen led him to the discovery of a tumor in the region of the left kidney early in April.

Early in May I was called by him in consultation, when the left side of the abdomen was found to be filled by a rounded, slightly nodular growth, which extended from the lumbar region to the median line laterally, and from the ribs down to the anterior superior spine of the ilium. Dr. Stedman and I (as did Dr. G. H. Lyman, and Dr. J. C. Guptill, of Northborough, subsequently) concurred in the diagnosis of enlarged kidney, probably malignant, which was apparently confirmed by a report from Dr. E. G. Cutler, that a specimen of the blood was "apparently not leucocythemic," and by the following result of an analysis of the urine by Prof. E. S. Wood: "Albumen, very slight trace. Considerable pus, some of which is in clumps; little blood; small round cells; an occasional small granular cast; no excess of bladder or vaginal epithelium." Dr. Wood appended these remarks, of which the accuracy was remarkably verified subsequently: —

"There is certainly some trouble high up in the urinary passages, but I cannot tell its exact nature. The absence of any excess of bladder or vaginal epithelium shows that the pus does not come from those membranes, and the absence of any large number of casts shows that it probably does not come from the kidney itself. The only other place is the pelvis of the kidney, and your tumor may be a dilated pelvis or *a morbid growth somewhat affecting the mucous membrane of the pelvis of the kidney.* But I cannot make a positive diagnosis. All that I can say is that the urine is not inconsistent with such a theory, and that there is probably some chronic inflammation of the pelvic mucous membrane."



On learning the desperate character of the growth the patient imperatively demanded the small chance of recovery held out to her through extirpation of the diseased kidney. On May 27th she accordingly entered my private hospital for operation.

In studying the literature of the subject, especially

[1] Read before the Obstetrical Society of Boston, June 14, 1884.

the recent papers by Drs. Harris[1] and Homans,[2] I was impressed by the idea, as I now think unduly, that one of the chief immediate dangers of the operation is deficient secretion of urine, for quite a number of the deaths, reported by these writers in their tables, were apparently attributed to "anuria" or "uræmia." In order to diminish the danger to my patient from this source I sought to stimulate her kidneys to secrete double the normal amount, and to reduce the amount of urea by restricting her diet to food containing but a small amount of nitrogen. By discontinuing the daily small amount of morphine (half a grain) upon which she had become dependent, by administering half a drachm of acetate of potash three times a day, I so far succeeded in my purpose as to increase the daily amount of urine passed from one pint to four pints, although it again decreased to two pints on the day before the operation. By a diet of milk and gruels I assumed that the excretion of urea was reduced to one half the normal amount, as has been demonstrated to result from such a diet. In other respects the woman's condition was fairly good, though she was much reduced in strength and flesh.

Tuesday, June 3, 1884. Operation at eleven A. M., assisted by Drs. C. E. Stedman, J. W. Farlow, and C. M. Green, in presence of Drs. B. Cushing, J. E. Kelly, R. T. Edes, and C. P. Putnam. Ether administered by Dr. F. H. Lombard. An incision about nine inches long was made in the median line of the abdomen, this location being selected because the tumor was manifestly too large for extraction through a lumbar incision, because for the same reason it was thought that an incision in the linea semilunaris would give a less easy access to the renal vessels, which it was my wish to ligate before I raised the kidney from its bed. The left rectus muscle was so rigid that it was found necessary to make a transverse incision, two inches long, through it at the level of the navel in order to expose the tumor. The stomach was found overlying the upper part of the tumor and was pushed upwards. The transverse colon crossed the tumor at its middle, its mesentery investing the lower portion of the tumor and containing many large vessels. The peritonæum investing the portion of the tumor about the colon was devoid of large vessels, and was consequently selected as the place for incision through which to enucleate the tumor. While incising this peritoneal layer every fine bleeding point was tied with silk sutures. The tumor was seen to be about the size and shape of an ostrich egg. Its lower rounded end was entirely invested with peritonæum, which was slowly peeled off with the fingers, every vessel which ran into the tumor being tied on both sides before being cut. The ureter, which passed to the right of the tumor and was not involved in it, was carefully avoided. The kidney rested upon the upper end of the tumor on its inner side, having been lifted from its bed by the tumor; it was closely bound to the tumor by adhesions, which were separated with but one slight laceration of the renal tissues, the oozing of blood from which was checked by the benzine cautery. At this point the pulse failed and respiration ceased, although not more than six to eight ounces of blood had been lost. Subcutaneous and rectal injections of brandy together with artificial respiration slowly revived the patient. The only remaining attachment of the tumor was to the subrenal cellular tissue; this, which could hardly be called a pedicle, was transfixed with a curved needle and tied in two halves. The tumor was now lifted out of the abdomen. The kidney, which was uninjured, except for the small lesions alluded to, and unimplicated in the growth, was put back in its proper site. All blood-clots were carefully wiped from out the peritoneal cavity, which subsequently remained dry. The two in-

[1] American Journal Med. Science, N. S., vol. lxxxiv. pp. 109–118, July, 1882.

[2] Boston Medical and Surgical Journal, vol cx., pp 73–77, January 24, 1884.

cisions were rapidly closed with silk sutures and the abdomen covered with borated cotton. The carbolic spray was not used, but otherwise the full antiseptic method was pursued. The room had been thoroughly disinfected on the day before the operation by burning sulphur in it.

The tumor was sent to Dr. W. F. Whitney, curator of the Warren Museum, who reported as follows: "The weight 650 grammes; it is an oval shape, being of the dimensions of $16 \times 8 \times 5\frac{1}{2}$ centimetres. The structure shows it to be a large round-cell sarcoma, but its origin and finer histology will have to be made out after hardening."

The operation was completed at one P. M. The curves of the pulse and temperature exhibit the changes in her condition for the thirty-two days subsequent to the operation. There was much pain and vomiting during the first week, and a tendency to collapse, which was met by morphine, stimulants, beef juice, champagne, coffee, quinine, etc., chiefly by the rectum. The bowels were moved by an enema on the eighth day. After the eighth day the food was given entirely by the mouth. On the thirteenth day a small abscess near the anus was lanced and some pus evacuated. From this incision a constantly increasing amount of pus escaped until her death, besides numerous large sloughs of the rectum and cellular tissue, constituting a large rectal fistula and pelvic abscess. The abdominal wound healed chiefly by first intention. The silk sutures were removed on sixth to ninth day. After the twentieth day a tumor began to form in the left hypochondriac region, from which six ounces of pus were drawn off by the aspirator on the twenty-ninth day. A second insertion of the aspirator obtained only fresh blood, presumably from the substance of the kidney. The tumor did not entirely disappear, but remained quiescent. The attempt was made on the fortieth day to make a permanent opening in the lumbar region at the point of the previous aspiration. No pus could be reached, but only blood smelling plainly of urine. The urine, for two days after, contained blood, and subsequently pus, until her death, which occurred from exhaustion at the end of the tenth week, owing to lack of recuperative power, and to the drain of the fæcal fistula, which never showed any disposition to heal. An autopsy was accidentally lost.

Before closing I must say a word about the secretion of urine and its character. The following table shows the amount passed in successive periods of twenty-four hours terminating at nine A. M.: —

Day before the operation	32 fluid ounces.
First day after the operation	7½ fluid ounces.
Second day after the operation	9 fluid ounces.
Third day after the operation	56 fluid ounces.
Fourth day after the operation	40 fluid ounces.
Fifth day after the operation	33½ fluid ounces.
Sixth day after the operation	40 fluid ounces.
Seventh day after the operation	56 fluid ounces.
Eighth day after the operation	45 fluid ounces.

Analyses of the urine, made by Prof. E. S. Wood: —

Day before the operation. "Specific gravity 1008. Very slight trace of albumen. Considerable pus, some of which is in clumps. Little blood. An occasional small granular cast. No excess of vaginal or vesical epithelium. Total amount of urea = 12.98 grammes. Total amount of phosphoric acid = 0.88 grammes. Total amount of chlorine = 2.535 grammes."

First day after the operation. "Specific gravity 1027½. A trace of albumen. Numerous granular, brown granular, and fibrinous casts. Very little pus and blood. Renal and pelvic epithelium."

Fourth day after the operation. "Specific gravity 1028. Very slight trace of albumen. Brown granular and fibrinous casts. Large brown renal epithelium, and very little blood. Better than the urine of the first day."

Seventeenth day after the operation. "Specific gravity 1016½. Very slight trace of albumen. *Very* little blood. An occasional blood corpuscle. An occasional hyaline cast and patch of pelvic epithelium. Slight excess of renal epithelium. There is very great improvement so far as the renal hyperæmia is concerned. There is a little pyelitis which, probably, will not last long."

This record shows that the immediate effect of the operation was to produce an acute hyperæmia of one or both kidneys and some pyelitis; that during the forty-eight hours immediately following the operation the amount of urine was greatly reduced, but after that fluctuated within normal limits. That the decreased excretion of urine was not due to the congestion of the kidney is evident from the fact that the amount of urine became and remained normal after the second day, although the hyperæmia persisted, with but gradual abatement, for three weeks and over. I have searched the daily bulletin of this case to explain the diminution and increase of the renal excretion.

Scarcely any liquid was taken by the mouth until after she had a dejection, on the seventh day. During that week she had frequent small enemata of concentrated beef juice, brandy, etc., the total volume of liquid absorbed into the system being small. She had, during the week, from half a grain to a grain of morphine subcutaneously each day. There was no special vomiting attributable to the ether, but frequent regurgitation of fluid throughout the week. The only possible clew which my record shows is derivable from the pulse and temperature curves. On these it will be noticed that the temperature was depressed for the first three days (which includes the day of the operation); that the pulse, though subject to fluctuations, ranged lower than on the subsequent days. For the week of observation before the operation the pulse had never been lower than 110, or the temperature than 100° F. These facts seem to me entitled to great significance in connection with the fluctuations in the amount of urine, and impel me to the belief that the marked deficiency in the amount of urine passed during the forty-eight hours following the operation is in this case attributable to the depressed state of the patient's system, that is, *shock*, and not to the fact of the interference with the kidney and the hyperæmia shown to exist. Applying the same reasoning to the cases of death after extirpation of one kidney, attributed directly or by implication to "anuria" or "uræmia," I feel justified in entertaining a doubt as to the correctness of the assertions. I have hitherto kept no exact measurement of the urinary excretion after severe abdominal operations, but recall distinctly several cases in which the volume of urine passed in the first few days was very small.

I do not believe that a dangerous deficiency of urinary secretion should be regarded as one of the perils of nephrectomy.

SICK HEADACHE.[1]

BY FRANCIS F. BROWN, M. D.

Sick headache, migraine, is a neuralgia. This is not the popular impression. Sufferers from it attribute it to "biliousness." The nausea and vomiting is proof positive to them that their trouble is due to derangement of stomach and liver, and that the headache is consequent upon it. This is not only the popular belief, but it was the doctrine of the systematic works until not many years since. In Wood and in Watson sick headache is discussed under the head of the digestive derangements.

That this disorder is a neurosis is evident from the behavior of the attack, its change in subsequent years into ordinary neuralgia, its local effects in some cases, and its hereditary character and connections with other neuroses.

First. I think no one can watch closely an attack of sick headache, especially if in his own person, without seeing evidence of its neuralgic character.

To begin with, there may be up to the time of the onset not the slightest symptom of gastric or hepatic derangement. The digestion may be perfect, the tongue clean, the bowels regular, there has been no error of diet; in short, evidence of indigestion or faulty digestion may be entirely wanting, and, the attack over, the digestive organs resume their functions perfectly, and continue to do their duty well until temporarily suspended by another paroxysm. Some feel unusually well on the eve of an attack. One gentleman tells me, "I never feel better in my life than the evening before I have sick headache. I go to bed feeling first rate." Persons subject to sick headache have usually premonitory symptoms which tell them an attack is impending. This is important to notice, because treatment, to be of avail to ward it off, must begin before the storm is in full blast. These premonitory symptoms are different in different persons, but are usually the same in the same person, so that the patient, although he cannot, perhaps, give a very clear description of his feelings, is made certain that one is coming. Some of them are sudden noises in the head, flashes of light or globes of fire before the eyes when they are closed, black spots, an appearance like a gauze veil quivering, ability to see only half an object, sleepiness, etc. Whatever they are the patient knows very well what they mean. Gradually or suddenly the pain comes on; it may be like a blow or in great waves advancing and receding. The pain may be principally in one eye or on one side of the head; it usually is worse on one side than the other, even when the whole head suffers. The pain deepens, nausea and vomiting occur, usually at first of mucus, and finally, if severe and prolonged, bile. This vomiting indicates the lowest point of depression of the vital forces. In some cases there is a tendency to sleep, from which the sufferer wakes only to retch and vomit. After a time the vomiting ceases, the nausea subsides, the headache diminishes, and if not gone by bed-time a good night's rest, in a majority of cases, finishes the cure. Soreness of the scalp at the seat of greatest pain may remain the next day if the attack has been severe, and soreness of the abdominal muscles if the vomiting has been prolonged is, naturally, to be expected. In a large majority of cases the whole course of the attack is passed through between sunrise and sunset or a little later. Some, however, and these are usually the hereditary and severer cases, suffer for two or three days of extreme wretchedness before the storm blows over. It is evident that this is something very different from the headache which is consequent upon gastric and hepatic derangement only.

Second. The neurotic character of sick headache is shown by its gradual change with the increasing age of the patient into ordinary neuralgia, preferably of the ophthalmic branch of the fifth nerve. These attacks, as one approaches fifty, become less severe, the nausea and vomiting less pronounced and less common, and what is left as a substitute is an occasional period of neuralgic pain through or over one eye or over one side of the head. At sixty sick headache ceases, as a rule. Anstie [2] says it begins at the age of from fifteen to twenty-five. I think sometimes we see it — or something like it — in young children of neurotic ancestry.

Third. Another fact, as given by Anstie, showing its neuralgic character, is the results which sometimes follow on the track of the fifth nerve, which is the nerve most affected, and the seat of greatest pain, namely, iritis, ulceration of the cornea, blanching of the hair or eyebrow, local anæsthesia and periostitis of the frontal bone. The four latter of these occurred in Dr. Anstie's own person; the local anæsthesia remained permanent.[3]

Fourth. Another point showing its character is the family relations of the disease. That it is often hereditary we all have had opportunities of observing, and the most intractable cases are among those who have had neurotic ancestors. It is closely allied with asthma and epilepsy, and is sometimes the precursor of the latter. It often occurs in persons among whose ancestors epilepsy has made its appearance. Careful inquiry shows that persons suffering from one of these frequently have had one or more of the others. These are the statements of Anstie in the very instructive article already referred to. I have under my own observation a case illustrating the close connection of migraine and asthma. The patient, a lady, has always been a great sufferer from sick headache, and cannot remember when she did not have it. Her mother was a like sufferer. For six years previous to 1882 she resided in Maine, and while there was comparatively free from migraine, but had asthma severely, from which she had been previously free. Since returning to Reading the migraine attacks have resumed their old frequency and severity, while the asthma has nearly but not wholly left her.

Sick headache is more frequent in women than in men, in those who are the subject of other neuralgias than the opposite, and in general is a disease of debility. To this latter statement there are apparent marked exceptions. Occasionally we find a subject of it who carries the appearance of robust health. My impression is that these cases usually belong to families who are subject to it or the allied neuroses. Notwithstanding these apparent exceptions it still remains true that the subjects of migraine, as a class, are below par in health, and apt to be ill nourished and anæmic rather than otherwise. Many, it is well known, in whom the migrainous tendency is not strongly marked remain tolerably free from attacks so long as their general health is good, but suffer frequently from them whenever their system becomes weakened and depressed.

[1] Read before the Middlesex East District Medical Society.

[2] Practitioner, November, 1872, p. 273.

[3] Practitioner, November, 1872, p. 276.

The immediate occasion of an attack may be anything which tends to exhaust the system, especially overwork, which wearies the body while it taxes and worries the mind, and loss of sleep. Any slight deviation from one's usual routine, like a shopping excursion, or late hours, loss of a meal, or eating at an unusual hour, will induce an attack in some persons. Gastric derangements, like any other, will occasion them, but the notion that so-called "biliousness" is the great cause of sick headache is a mistaken one. The trouble commences at the other end of the line, and the nausea and vomiting are secondary. This does not lessen the importance of keeping the digestive system in good order. But in typical migraine I think exhaustion or loss of sleep is the occasion of ten attacks to one where indigestion is the cause. Undigested food is, I think, not usually seen in the vomit of migraine.

In treatment we aim, first, to avert an impending attack; second, to put the system into such a condition as to render it less liable to one.

First, to avert an impending attack, the most efficient remedies are guarana and caffeine. Thirty grains of the powder, or a teaspoonful of a good fluid extract of guarana, or three or four grains of caffeine, should be given every twenty minutes or half hour till three doses are taken, unless the symptoms sooner show signs of abating. This is a point I wish to emphasize strongly; it is the key to their successful use, namely, to give full doses, and to give them in the very first threatenings of an attack. Your patient will generally know when one is coming. Usually it is useless to give them after the storm is in full blast, though sometimes I have thought its duration was thus somewhat lessened.

Attention to some minor points may aid in averting an attack. When the patient has undergone any unusual fatigue or loss of sleep, anything which his own experience leads him to suspect will be followed by sick headache, I think, I feel quite sure, that a full dose of bromide of potassium, thirty to sixty grains at bed-time, will lessen his liability to it. This drug is useless, it seems to me, after the attack has begun. Under the same circumstances, if the patient is at all constipated, an aloetic laxative, like the old-fashioned *pil Rufi* (one at bed-time), is serviceable. If this has been neglected, a dose of citrate of magnesia may well be taken in the morning with the caffeine. This can usually be tolerated by the stomach. So trifling a matter as slight constipation appears at times to turn the scale under these circumstances.

These are the measures which have usually afforded more or less relief in my own attacks, and in a majority of my patients who have tried them. Many attacks may be wholly averted, in others a dull headache remains as a substitute for an outrageous one. I am bound to admit that in many cases also they fail, but in which ones I cannot tell except by trial. Treatment is most likely to fail in those whose hereditary neurotic tendency is strongly marked, and in those whose circumstances necessitate at times unusual strain and draft on the system. The subject of migraine is like a man whose balance at the bank is always small and soon overdrawn, his other assets are not immediately available; though not bankrupt he is often distressingly hard up. Perhaps this provision of nature is, after all, conservative and salutary, in that it teaches its subject by sharp suffering the limits beyond which he must not pass. And this suggests the question, are the subjects of this disorder, as a class, short lived? My impression is that they are not.

Of more importance than to repel a single assault is it to so fortify the system that none will be made. How to do it must be left to the judgment of the physician in view of the needs of each individual case. Every drain and tax and irregularity that the patient has learned by experience invites an attack must be looked after and stopped. Loss of sleep and irregular hours must be prevented. Over-lactation may be the trouble with one, excess of venery with another, abuse of tea or coffee or tobacco with others, over-feeding with some, under-feeding with many more; this latter is not infrequent, from a notion that in the stomach or liver lies the root of the difficulty. In general build up the patient's health and strength by whatever means seem most indicated. If anæmic, of course give iron. Generally, I think tonic doses of quinine, or of some one of the preparations from Peruvian bark, are of as much service as any one drug. Arsenic is highly commended by some. One of my medical friends who has had considerable personal and other experience with this disorder is certain that one fiftieth grain doses of the iodide of arsenic three times a day, continued for a considerable period, diminishes the frequency and severity of these attacks. If there is the slightest constipation use laxatives, preferably, I think, the aloetic, but avoid purging. A full diet is generally indicated. The physician or nurse when doing night work should not fail to take food in the night. Fasting then makes one doubly liable to an attack the next or second day. The use of fat food, cream, and cod-liver oil is strongly recommended by Anstie in this as well as neuralgias generally. A careful and persevering use of such means will, I am satisfied, in a great majority of cases diminish very much the frequency and severity of these attacks.

I wish to add a few words about the use of cannabis indica. In this drug I believe we have a remedy of great value in migraine. My attention was particularly called to it by an article in the *New York Medical Record* of December 8, 1877, by Dr. Seguin, who says that in doses of one third to one half grain of good extract, thrice daily, continued for months, not less than three, it diminishes in a marked degree one's liability to these attacks. My experience of course has been quite limited, but I have had a few patients whose improvement from its use, after the failure of tonic treatment alone, has been very marked. One case, a lady of thirty-three, — whose mother suffered all her life from migraine, and father from migraine and asthma, — who had been having attacks increasing in severity and frequency for months, till she was having one nearly every week, each attack lasting two or three days, experienced immediate relief, and while she had threatenings did not have a decided attack for six months. This was three years ago; her improvement, though not immunity, has continued.

Though some begin to feel relief at once, the drug should not be considered to have had a fair trial till after months of continuous use. I have seen patients relieved after persevering four or five months who saw little or no benefit in three. The notorious uncertainty of the quality of this drug is a decided drawback to a satisfactory trial of it. What proportion of cases will be benefited by it, and how permanent will be the relief, I am not prepared to say.

A GAS FURNACE FOR FIRING DENTAL ENAMELS AND PORCELAINS. CAUSES OF "GASING" IN FIRING TEETH.[1]

BY WILLIAM HERBERT ROLLINS.

THE two subjects are combined because by means of the former I have been able to discover the latter.

The furnace shown in Figures 1 and 2 will give a

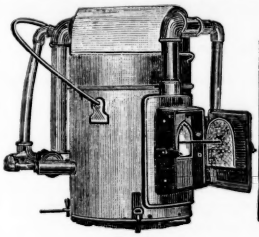


FIG. 1.

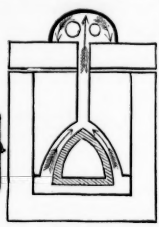

FIG. 2.

heat from a dull red to a light so bright that an object in the muffle is invisible. Looking at the figures will enable any dentist, by means of the following brief description, to make a similar one: The furnace consists of a cylinder of sheet iron ten inches in diameter and eleven inches high. It has a handle and an iron door. The cover is a similar cylinder two inches deep. Both are lined with porous fire clay two inches thick. The furnace walls have four holes in them. Three of these holes give passage to three tuyeres, the fourth is for a No. 3 muffle, the mouth of which is closed by an iron door lined with asbestos. The door is perforated by a platinum tube, through which passes the platinum trial rod with a small spoon end for the test piece. This rod can be withdrawn from time to time to look at the test piece. At the front of the furnace are two iron tubes, one for gas, the other for air. These pass under the fire-clay arch, where they are brought to a yellow heat by the waste gases as they escape through the slit in the top of the furnace. See Figure 2. Each of these tubes divides into three branches at the back of the furnace where the gas tubes enter the air tubes. In this way three double tuyeres are made, their mouths corresponding with the holes in the furnace. This arrangement is necessary, for if the heated air and gas are allowed to mix before reaching the mouths of the tuyeres these would be destroyed by the intense heat. Figure 2 is a perpendicular section of the furnace. The course of the heated gases is indicated by the arrows. A similar furnace for dental metallurgy will be described in another paper.

Any one familiar with the metallurgy of iron will see that the principles which have been used were discovered long ago. The hot blast was invented by Neilson in 1830. Siemens used gas as a fuel, and heated both this and the air. Using the waste gases to heat the blast is not new. Naphtha has been used to increase the illuminating power of gas, and knowing this, its value for increasing the heating power would occur to any one. Porous fire clay was known in Strabo's time, though T. Fletcher, with his usual capacity for adopting other men's ideas and giving them no credit, has recently reinvented it.

Though the principles were discovered long ago they had never been used together, and by this new combination I have been able to do what has never been done before in a gas furnace, produce heat enough to bake teeth, and this, too, in so short a time as forty minutes from the time the gas is lighted.

CAUSES OF GASING IN FIRING MINERAL TEETH.

In my first experiments for making enamels for filling conspicuous cavities in teeth difficulty was sometimes found in making the enamel base of a pure translucent white. As the result of somewhat elaborate tests it was found that the gray or green tint was due to the reduction of some of the lead oxide. A similar difficulty was encountered when the enamel base was fritted with the metallic oxides necessary to give it the shade of the teeth. Here the oxides themselves were reduced.

It therefore seemed probable that the so-called gasing in mineral teeth came from a similar cause.

Many experiments and analyses were made to test the matter, and though it is not worth while to give these in detail, one experiment, which is easily tried, will be mentioned: After having made a furnace like the one described, light the gas and open the air valve. When the heat is high enough put an unbaked tooth into the muffle. When taken out the color will be pure. Now diminish the oxygen by partly closing the air valve. Put in another unbaked tooth. When this is removed it will be found gased. The same result will follow with the air valve in the same position as in the first experiment if the supply of gas is increased. In experiments with dental enamels and porcelains it is advisable to have a slight excess of air in the furnace. Where the color used, as, for example, platinum, yields the proper tint in the metallic state this precaution is unnecessary, as in these cases the color has no oxygen to give up.

[1] Abstract of a paper read before the Society for the Advancement of Oral Science, June 21, 1880.

Reports of Societies.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M. D., SECRETARY.

JUNE 14, 1884. The President, DR. C. ELLERY STEDMAN, in the chair.

EXTIRPATION OF A RETRO-RENAL SARCOMA BY ABDOMINAL SECTION.

DR. J. R. CHADWICK read the paper.[2]

DR. C. E. STEDMAN said he had first seen the patient two or three years ago, when he was called to draw her urine. He had seen her again about a month before the operation: she was then rapidly emaciating and growing weak: she complained only of pain in the back, the pain and weakness being her only symptoms. He had found a tumor in the region of the left kidney.

DR. BLAKE asked if the tumor had interfered with the functions of the kidney.

DR. CHADWICK said that from his examination of the urine Dr. Wood was led to think that there was some lesion of the pelvis of the kidney.

[2] See page 388 of this number of the JOURNAL.

DR. BLAKE inquired if the kidney showed any effects of pressure.

DR. STEDMAN thought the kidney was a little redder than usual.

DR. BLAKE thought it was best to avoid transverse incisions of the abdomen, as there was liability to herniæ.

DR. CHADWICK said the transverse incision was an apparent necessity in this case, as he believed at the time it would be necessary to tie the renal vessels. He used silk ligatures and sutures. In reply to a question by Dr. Blake, Dr. Chadwick said that no glandular infiltration was observed.

DR. BLAKE said that run-down patients recover better after operations than those in the full flush of health.

DR. DAVENPORT observed that Keith had found in seventy cases that recovery was slowest in tapped and run-down patients. He thought few cases died of peritonitis; that few, in fact, have it, except a slight local peritonitis. He had noticed after operations a diminished amount of urine, and thought the diminution might be due to the ether. He asked the reader if he thought the scanty secretion of urine was due to the operation.

DR. CHADWICK did not know what effect on the kidney was caused by abdominal operations, but thought that in some cases of nephrectomy the small amount of urine had been assigned as the cause of death. He thought the diminution might be attributable in part to the diminished amount of ingesta and to the use of opiates.

OBSTINATE VOMITING OF PREGNANCY: INDUCED ABORTION: RECOVERY.

DR. FIFIELD reported the case, which he had seen in consultation. The patient was about three months pregnant, and for two weeks her attending physician had tried unsuccessfully to relieve the obstinate vomiting which was rapidly exhausting her strength. Oxalate of cerium, morphia, and other remedies were employed, also applications of iodine and nitrate of silver to the cervix, but all without effect. Rectal enemata were not well borne. It was decided to induce abortion, as the patient was sinking rapidly: Dr. Fifield therefore introduced a bougie within the uterus and waited twenty-four hours; but no result followed. A second bougie was then introduced to the depth of several inches, also without effect. Dr. Fifield then passed a sound into the uterus and moved it freely about: no pain was caused thereby and no blood followed the withdrawal of the sound; but the next day the fœtus was discharged with unbroken membranes. The change was marvelous: food was retained the same day, the color came back, the bowels, which had been obstinately constipated, resumed their function, and the patient was up and dressed at the end of a week. In passing the sound Dr. Fifield observed that the uterus was much anteverted, and he alluded to the fact that in fœtuses and young infants the uterus is anteflexed and bent to the left.

DR. BLAKE regretted that one need ever to resort to the induction of premature labor for the relief of vomiting: he had always found that some other treatment sufficed: he thought counter-irritation was often efficient, with regulation of diet or rectal alimentation. If patients with gastric ulcer or intestinal obstruction. can be tided over with rectal alimentation, why not pregnant women?

DR. CHADWICK had not always seen blood follow the introduction of a sound, even when passed for inducing labor.

DR. RICHARDSON had seen a woman three months pregnant and near death from vomiting, into whose cervix he inserted two laminaria tents and dilated the os. Abortion did not occur; but immediate improvement followed, and the patient was able to take egg nogg.

PLACENTA SUCCENTURIATA.

DR. W. L. RICHARDSON reported the following case: —

P. T., primipara, twenty-two years of age, entered the Boston Lying-In Hospital May 31st with this history: She was about nine months pregnant and expected to be confined at any moment. May 27th she had some flowing, without any assignable cause, lasting two days. She appeared on entrance very feeble and pale. She was put to bed and nourishing diet ordered. June 1st. Some flowing, which continued slight until the 4th, when flow increased. An examination showed the external os admitting the finger; on the side of the internal os placental tissue was felt: a diagnosis of low attachment of the placenta was made.

June 5th. She was delivered of a boy weighing six and three quarters pounds. The placenta was expressed with some difficulty, and was of normal size. Connected with it was a placenta succenturiata (three by four inches), oval in shape, and attached along the side of the internal os.

June 21st. Mother and child discharged well.

NATIONAL CONFERENCE OF STATE BOARDS OF HEALTH, ST. LOUIS, OCTOBER 13, 14, 15.

FIRST DAY'S PROCEEDINGS.

THE National Conference of State Boards of Health assembled for its annual meeting at Liederkranz Hall, St. Louis, Monday, October 13th, HON. ERASTUS BROOKS, of New York, occupying the chair. The meeting was an especially important one, as it was understood the questions concerning a possible invasion of cholera would be discussed. The following representatives of State Boards of Health were present: —

Arkansas, Dr. J. A. Debrell, Jr.; Connecticut, Dr. C. A. Lindsley; Illinois, Dr. J. H. Rauch; Kentucky, Drs. J. O. McReynolds, J. N. McCormack; Louisiana, Drs. L. F. Salomon, S. S. Herrick; Massachusetts, Dr. H. P. Walcott; Michigan, Dr. Henry B. Baker; Minnesota, Drs. D. W. Hand, W. H. Leonard, C. N. Hewitt; Missouri, Dr. J. C. Hearne; New Hampshire, Drs. I. A. Watson, G. P. Conn; New Jersey, Dr. E. M. Hunt; New York, Erastus Brooks; Rhode Island, Dr. C. H. Fisher; South Carolina, Dr. T. G. Simons; Tennessee, Drs. J. B. Lindsley, G. B. Thornton; Texas, Drs. R. M. Swearingen, J. L. Carter; West Virginia, Dr. J. E. Reeves; Wisconsin, Drs. J. T. Reeve, S. C. Johnson; Ontario, Dr. P. H. Bryce; Canada, Dr. C. W. Covernton.

In calling the meeting to order the CHAIRMAN said it would be useless to repeat what had been so often urged in the past in regard to the great importance of

State Boards of Health. He was glad to think that so many States of the Union already possessed these organizations, and felt sure that those which were still without them would soon recognize their utility. In his own State he was happy to say that local organizations have been completed in 900 towns, in nearly every one of the 240 villages, and in twenty-four of its cities. And this had been accomplished rather by persuasion than by force, although the State gave them unlimited power to establish organizations in the various towns and villages.

The minutes of the last meeting, held at Washington, May 7, 1884, were read by the secretary, DR. J. N. MCCORMACK, and accepted.

PLAN OF ORGANIZATION.

DR. HEWITT, in behalf of the State of Minnesota, presented a plan of organization, the main points of which were as follows: The establishment of a body to be known as the Council of State Boards of Health of the United States; the officers to consist of a chairman, corresponding secretary, recording secretary, a treasurer, and an executive committee, the latter to consist of one member from each State Board. The objects of th eorganization were to cultivate a closer acquaintance between officers and members, to facilitate discussion of sanitary work, and to give better opportunities for comparing and discussing methods.

DR. RAUCH moved that the plan be referred to a committee of five, of which the chair and secretary be ex-officio members.

DR. BAKER offered an amendment that the report of the committee be received at the next annual meeting. The motion as amended was then carried, and the Chair appointed as the remaining members of such committee Drs. Rauch, Hunt, and Hewitt.

THE AMERICAN PUBLIC HEALTH ASSOCIATION.

An invitation from the American Public Health Association to the members of the Conference of State Boards, asking them to contribute papers and be present at a special session on Wednesday, was accepted with thanks.

The question whether papers prepared for the Conference should be reserved for the American Public Health Association aroused a warm discussion. DR. RAUCH said he proposed to deal with men who would give orders when the cholera came, and not with men who would hold sanitary prayer meetings. He had prepared a paper to be used as a nucleus for discussion at the Conference of State Boards of Health, and not at the American Public Health Association.

DR. SALOMON indorsed these views, and thought the two bodies were entirely distinct organizations and had different spheres.

Several other speakers expressed similar sentiments, Dr. DEBRELL stating that the principal thing that brought the Conference together was to devise means to keep cholera out of the United States. He valued the American Public Health Association, which has members all over the country, but he thought in moments of emergency it did not have the same power that State Boards of Health had.

The CHAIRMAN thought that the two associations ought to act in harmony, and that there was no necessity for any rivalry or recrimination.

PAPER BY DR. RAUCH — EFFICACY OF QUARANTINE AND THE RIGHTS OF STATES.

DR. J. H. RAUCH, of Illinois, then by general request read the paper which he had prepared for the meeting. It was virtually a presentation of the efficacy of quarantine and of the rights of individual States to keep their own borders free from contagion. He stated that Illinois, the largest internal tax-paying State in the Union, was vitally interested in the manner in which quarantine was enforced in New York and Eastern ports. He asserted that his wide range of experience in all cholera epidemics has convinced him that cholera is conveyed only by means of infected persons, and hence there was no necessity for guarding against merchandise, rags, etc. The Illinois State Board of Health would have the right to close up the Illinois end of the St. Louis bridge if the great city became plague-stricken. The State would also have the right to stop the Great Canada Southern Railroad from entering the State territory if the authorities thought Canada was afflicted with cholera. The same could be done on all lines, and all States had the same power, and it was only a mere question of assertion. For a period of six years sanitary officers and sanitary authorities have had no great demand made upon them. During these six years the interest in sanitary matters raised by the epidemic of 1878 — the yellow fever epidemic — has gradually diminished. When an epidemic actually exists and industry and commerce are paralyzed there is then no question in the public mind as to the desirability of sanitation, no hesitancy in making appropriations. But Rabelais told us nearly four hundred years ago what the devil did when he got well. The Forty-eighth Congress adjourned in spite of the fact that an epidemic was staring us in the face, after rendering inoperative all previous legislation on sanitary matters. It is now our imperative duty as sanitary officers to awaken public interest and to prevent the introduction of the epidemic of Asia to our shores. Much has already been done by the action of national and State authorities, and since the 2d of July last, over sixteen States have issued circulars of admonition.

In conclusion Dr. Rauch said: —

Congress should be urged to reorganize and rehabilitate the National Board of Health, or to provide an efficient substitute, one clothed with increased power and supplied with ample funds to maintain an effective system of modern sanitary quarantine for the exterior; to maintain an interior sanitary inspection service for the great highways of travel by rail and river; and to give judicious coöperation and substantial assistance to States and municipalities in preventing the introduction of epidemic diseases into one State from another, and their spread within the States themselves. Congress should give the President the power to issue a proclamation upon the recommendation of the national health authority forbidding immigration into the United States from infected districts; and it should provide some method of international sanitary coöperation between this country and the Dominion of Canada, whose interests are substantially the same as ours in these matters, and whose contiguity makes coöperation of vital importance. In States which now have no boards of health, or whose boards are not vested with the necessary authority or provided with adequate resources, the people should be awakened to the necessities of the situation. Legislators should be thoroughly informed as to the

facts, and urged to provide suitable legislation. Information on sanitary matters should be widely diffused to this end, and also to the end that, if an epidemic should come, we may not have to encounter the obstacles which ignorance is always ready to put in the way of what it does not understand. Happily, in this country, we are not likely to meet with the treatment that the superstitious peasantry of France and the lazzaroni of Italy have accorded their physicians and health officers. But sanitary education and knowledge cannot be too wide-spread. These are matters which may profitably occupy much of our time and attention for the next two months; and I would suggest that when this meeting of the Conference adjourn it be to meet again in Washington in December for the purpose of conferring with the President, the cabinet officers, and the committees of the Senate and House as to the legislation which should be asked for at the next session of Congress. To this meeting I think not only should representatives of State Boards of Health be invited, but also all quarantine officers and health authorities of all the large cities, as well as those of the Dominion of Canada. I would also suggest that quarantine officers should be requested to come prepared to give all necessary information concerning the quarantine affairs of their respective ports.

THE VIEWS OF THE NATIONAL BOARD.

DR. CHARLES SMART, surgeon of the United States army and member of the National Board of Health, upon special invitation, read a paper outlining the methods of disinfection and quarantine used by the National Board. The Board based its rules and regulations for preventing the introduction of cholera into the United States, and its spread from one State to another upon certain incontrovertible facts demonstrated by science and experience, among which were the following: —

That cholera is caused by a specific germ, and that this germ may be destroyed with no other interruption to travel and traffic than is needful to discover its presence and so apply the necessary means for disinfection. In order to secure international coöperation a conference was held at Washington in 1881, and, of twenty-seven nationalities represented, the larger number were prepared to enter into a joint treaty that would secure harmony of action. The first step taken by the National Board was to frame rules and regulations to be enforced at foreign ports to secure the best sanitary condition of vessels about to leave for a port of the United States. Ships are the great carriers and propagators of diseases of foreign origin, and the modern emigrant ship is a vast field for the cultivation of pestilence. Sanitary service at sea, for securing at the foreign port a clean vessel and uninfected freight, also commanded the attention of the Board. On the arrival of vessels at any port of the United States proper steps were laid down by the Board for the prevention of the entry of any infected boat. Every vessel was visited by the quarantine officers and all needful precautions taken in case of suspicion of pestilence; clothing, baggage, and cargo were carefully disinfected. If, in spite of all these precautions, the disease effected an entrance into any port, measures were taken to prevent its spreading from that port to other ports on the coast, or to interior points. Sea-coast, river, and railroad travel, and transportation were conducted under sanitary supervision. In the case of coast or river steamboats or vessels sailing from the infected port, measures of inspection and disinfection were enforced similar to those practiced at foreign infected ports. In addition to this, inspection stations were established at certain points on the Mississippi River, the medical officers of which acted as quarantine officers for the States threatened with invasion.

In conclusion the reader made some additional recommendations for the establishment of a more rigid local quarantine.

DISCUSSION.

DR. BAKER moved that all papers read be referred to a special committee of five for consideration. The motion was carried, and the Chair appointed as such committee Drs. Baker, Rauch, Walcott, Bryce, and Herrick.

The chairman, MR. BROOKS, opened discussion on the papers by a warm defense of the sanitary officers of New York. He said that so far as was morally and physically possible everything had been done to prevent the introduction of cholera into New York, and what had been done had been well done. The arrangements were so complete that, under the guidance of God, it was impossible for cholera to be introduced into that city. He made that explanation because New York had, unintentionally, perhaps, been unjustly censured in one of the papers.

DR. J. B. LINDSLEY, of Tennessee, said: "I am personally familiar with every cholera epidemic that has visited the United States, going back fifty years and standing by the graves of persons taken off by cholera in 1833. Never has cholera come to Europe without coming to America; never has it come to America without coming to Tennessee and sweeping the State from one end to the other. But never were the people of my State as frightened as are the people of France and Italy to-day. The people of Tennessee have given the State Board of Health of Tennessee the power, if one case of cholera appears in Chicago, of stopping the Illinois Central Railway. If one case of cholera occurs in New Orleans the State Board will stop the same vehicle from the South. If one occurs in New York the same thing will happen, and six great lines of transportation from north to south and at least a billion of dollars will be stopped in less than twenty-four hours."

DR. C. W. COVERNTON said he remembered everything connected with cholera since 1830. Filth is the gunpowder and the germ is the disease. If we keep away filth we are all right.

DR. CONN moved that, inasmuch as the Conference had no funds for the printing of Proceedings, the conclusions of the committee to whom the papers had been given should be referred to the American Public Health Association. This was agreed to, and after refusing by a vote of eleven States to five to reconsider the vote by which the committee having charge of the scheme of permanent organization were instructed to report at the next annual meeting the Conference adjourned until Tuesday.

SECOND DAY'S PROCEEDINGS.

The Session of the second day, Tuesday, October 14th, was a prolonged one; a paper by Dr. C. W. Chancellor, of Maryland, on the Non-Contagiousness of Cholera and the Inadequacy of Quarantine, and the

report of the Committee to which Dr. Rauch's paper of the previous day had been referred, giving rise to an active discussion, in the course of which, as was to be expected, a good deal of difference of opinion was manifested on the two principal points at issue, the contagiousness of the disease and the value of quarantine.

DR. CHANCELLOR'S PAPER. — THE NON-CONTAGIOUSNESS OF CHOLERA AND INADEQUACY OF QUARANTINE.

Dr. Chancellor, in his paper, took the ground that cholera was not contagious, and said there was hardly an instance of more stupendous folly than the attempt to prevent the spread of cholera by a system of sanitary cordons. Quarantine was not only useless, but it was a positive injury, because it prompted a false feeling of security and the neglect of other precautions. The history of cholera since 1817, when it first became known as such, having its origin in India, established, first, that sanitary cordons were unavailing, and secondly, that persons were afflicted with the disease who had not come in contact with the sick. If cholera was in the air it broke out in communities where there had been no ascertained introduction of the disease, but it was noticed that it gained its first hold and raged with greatest virulence where non-sanitary conditions prevailed. Dr. Chancellor cited a great array of instances in support of this view. Measures of isolation and of non-communication were futile, he declared. But though quarantine cannot be depended upon, the powers of government, national, State, and municipal, must be exerted to disarm the disease when it does come. The only practical work was to remedy the conditions favorable to the disease and let the germs take care of themselves. The best plan, he thought, was to establish without delay intelligent forces of sanitary inspectors. Ventilation and drainage must receive careful attention from all classes. Temperance and abstinence from unhealthy food and from intoxicating liquors must be urged upon the people. Warning should be given against exposure to excessive fatigue, and finally it should be the policy of the State Boards to tranquillize communities and inspire confidence.

Some approbation was manifested upon the termination of Dr. Chancellor's paper, but it was evident that the majority of those present were still disposed to rely upon quarantine in some form or other as a protection against invasion.

Dr. Holt, of the Louisiana Board, urged a quarantine, not of the old shotgun style, but intelligent provision for the detention of ships and the thorough cleansing of the hulks and the disinfecting of the contents before they were allowed to come into port.

Dr. Reeves, of the West Virginia Board, deplored the views of Dr. Chancellor, if that meant no quarantine at Baltimore. Of what use would be any precautions adopted by West Virginia.

Dr. Stewart, of Baltimore, assured Dr. Reeves that there wasn't the slightest danger of his port being thrown open.

REPORT OF COMMITTEE ON PRACTICAL WORK REQUIRED FOR THE PREVENTION OF CHOLERA IN THIS COUNTRY.

The committee, consisting of Drs. Baker, Walcott, Herrick, Rauch, and Bryce, to which Dr. Rauch's suggestions as to the "Practical Work required for the Prevention of Cholera in this Country" had been referred, having drafted its recommendations, reported as follows: —

Origin and Dissemination of Cholera.

There are three essential factors to the prevalence of cholera in this country as an epidemic: (1) The importation of the disease by means of ships more or less directly from its only place of origin in India; (2) local unsanitary conditions favorable to the reception and development of the disease; (3) persons sick with the disease in some of its stages, or things infected by such sick persons, to carry it from place to place. These three factors naturally suggest the methods of combating the disease, for which there is needed practical work, international, national and inter-State, State and local. So far as relates to State and local boards of health, their organization and activities are greater than ever before; but it must be admitted that after cholera has been introduced into a country inland quarantines are not easily and successfully maintained, although efforts in this direction are then advisable. In view of the threatened introduction of cholera into this country during the coming year, and the consequent immense waste of life and property values through derangements of commerce, trade, and productive industries, it is the sense of this Conference that the general government should maintain such a national health service as shall, by rigid inspection at the port of embarkation, question the freedom from disease and infection of all persons and things from infected districts; and shall secure the surveillance of such persons and things while on shipboard, and, when necessary, detention at quarantine stations on this side for treatment and disinfection.

Official Inspection.

In view of the present threatening aspect of Asiatic cholera, and the constant danger from other communicable diseases occurring at foreign ports having commercial relations with the United States, we urge upon Congress to provide for the appointment and maintenance at all such foreign ports where cholera, yellow fever, plague, small-pox, or scarlet fever exist, or are liable to exist, of medical officers of health, the same being either accredited consuls or attached to the consulates. The duties of these officers shall be: To give notice, by telegraph when practicable, of the existence or appearance of any of the above-named diseases to some constituted authority in this country; to give notice of the departure of any vessel known or suspected to be infected for any port in the United States; and, whenever requested by the master of any vessel about to load or leave for this country, to inspect thoroughly such vessel in all her parts, and also her cargo, her crew and passengers; to use such cleansing and disinfection as he may deem necessary, and to satisfy himself that all persons about to sail are free from dangerous communicable diseases, are not recently from infected places, and are properly protected from small-pox, giving to her commander a certificate of the inspection and of all precautionary measures taken. And it shall be the duty of the central authority in this country to transmit promptly intelligence of the existence of the above-mentioned

diseases at foreign ports and places, and of the departure of dangerous vessels for the United States and Canada, to all State and local health authorities in the country which may be interested in the same.

We further recommend, in case of those foreign ports which have no consular agents in this country, or no telegraphic communication with this country, and which are liable to transmit pestilence through commercial intercourse, that one or more medical officers be chosen to visit such ports as often as may be deemed necessary by the central health authority in this country, so as to give trustworthy information of the health and sanitary condition of those places.

Canadian Health Alliance.

Inasmuch as the Dominion of Canada is equally interested with the United States in protecting itself and the United States from the importation of dangerous diseases we suggest that Congress take such measures as will bring about concerted action with the Dominion and the British government by which the consuls of this country or of England at foreign ports shall examine and take such action as they may deem effective, and notify the authorities of such government as has authority over any port to which any ship may sail in the United States or Canada, in order that such government may be in a position to take effective measures against the importation of these diseases. We are gratified that the authorities of the Dominion of Canada and of the Province of Ontario have taken active steps toward protecting the people of Canada and, indirectly, those of the United States, by the adoption of extensive quarantine regulations. We feel, however, that with respect to those regulations regarding the landing of passengers from the mail steamers along the St. Lawrence, etc., further special regulations for the thorough disinfection of the baggage and effects of all passengers, cabin or steerage, who come from infected ports and places, should be carried out in a manner similar to that recommended by the National Board of Health. Believing that the importation of cholera into this country has usually attended the presence of immigrants from infected countries we therefore recommend that all such immigrants be prevented from landing at our ports until such time as the danger of the introduction of cholera by them shall have passed.

The Inspection and Quarantine Service inaugurated by the National Board of Health, and set forth in the paper by Dr. Smart before this Conference, but which system is now inoperative for want of an appropriation by Congress, meets with our cordial approval. To enable these protective measures to be carried out we recommend that Congress be urged in the strongest terms to legislate on this subject at an early date in its coming session, and to appropriate such funds as may be needful. The expenses incident to the work which has to be performed at foreign ports, and the establishment of refuge stations at points on our coast for the detention and treatment of infected vessels arriving from foreign ports, should undoubtedly be borne by the national government, and not by individual States or municipalities, for the benefits accruing therefrom are general and not restricted to localities, although some ports and cities on the coast may have a more immediate interest in the matter than others in the interior. It is probable, however, that this national protective work may not be sufficient.

Local Safeguards.

It will undoubtedly delay and lessen the chances of invasion, but it may not prevent invasion; the poison of the disease is subtle, and may effect an entrance into the country at some unguarded point. The funds necessary to the stamping out of the disease in a particular locality, and to the prevention of its spread to other localities, might in some instances be borne by the municipality or State affected; but should the disease occur in a locality which has failed or is unable to make provision for the occurrence, its spread to other cities and States would be imminent. The want of means at the infected point would be disastrous to many others. Congress has recognized the necessity for aid to State and local boards of health under similar conditions in the case of yellow fever. In 1879 the sum of $500,000 was appropriated and placed at the disposal of the National Board of Health; and the records show that of this sum $160,000 was employed in combating the epidemic of that year. We therefore recommend that the influence of this Conference be used with the view of having apropriated by the National Legislature the sum of $500,000, to be used, or as much thereof as may be needful, in case of a cholera invasion, in stamping out the disease from the infected localities, and in preventing its spread from State to State.

The removal of local unsanitary conditions favorable to the development of cholera is the especial work of State and local boards of health. Much has been done already in some States, but much remains which should receive immediate attention. Where it can be done, State sanitary inspectors should be appointed to visit all towns and cities specially liable to the disease, to counsel with the local authorities as to the best methods of prevention. This work should be vigorously prosecuted before the disease reaches our shores.

Health officers and inspectors appointed by State or provincial boards of health should, in addition to other sanitary work, see that the localities have set apart, erected or planned to be set apart or erected, structures which shall possess the sanitary requirements of an isolation hospital. But as regards all necessary work by local boards of health, most State and provincial boards of health have printed and issued documents which give ample instructions.

Advice to Citizens.

The cause of cholera is contained in the discharges from persons affected by the disease, or in things infected by such discharges. Should the disease reach our shores, the first case, and after this the first case which reaches any given community, should be strictly isolated; all infective material from these and from any subsequent cases should be destroyed in such manner as to stamp out the disease.

Your committee recommend that when this Conference adjourns it be to meet in Washington, D. C., the second Tuesday in December next, and that the secretary of this Conference be directed to invite the attendance at that time of the quarantine officers and the health officers of the principal cities in the United States and Canada, and that all delegates to that meeting be prepared to report the sanitary status of their State or locality, and what steps have been taken to improve the same and to prevent the introduction of disease.

The reading of these recommendations gave rise to some discussion, in the course of which Dr. Chancellor said had he known what the committee was going to recommend he might have kept his paper in his pocket. He believed in the majority ruling, and if it should appear that most of the States endorsed the recommendations he would vote for them too.

On the ballot all the States voted in support of the report save Minnesota, and the point made by the Board of that State was that the recommendations were so important that more time should be taken for their consideration.

The Conference then adjourned until the following afternoon.

Wednesday, October 15.

The recommendations for practical work indorsed by the American Public Health Association.

The draft of recommendations for practical work to be done to prevent the entrance and spread of cholera in the United States was presented to the American Public Health Association by Dr. J. N. McCormack, secretary of the Conference of State Boards of Health.

Drs. Hunt, of New Jersey, and Devron, of Louisiana, favored the adoption and publication of the recommendations by the Association.

Dr. Pinckney Thompson, of Kentucky, considered internal quarantine or sanitary cordons of very little use in stamping out cholera which had once effected an entrance into the country.

Hon. Erastus Brooks, of New York, moved that the communication be indorsed by the Association, printed, and copies be forwarded to the President of the United States and his Cabinet, and to each of the Senators and Representatives of the National Congress.

Dr. Watson moved an amendment that a sufficient number of copies of this report be sent to the health offices of the different boards of health and the officers of the Dominion of Canada boards.

The motion, as amended, was adopted.

NEW YORK ACADEMY OF MEDICINE.

At a stated meeting held Thursday evening, October 16th, Dr. H. M. Sims presented to the Academy a beautiful bronze bust of his father, the late Dr. J. Marion Sims, which he had had executed in Paris during the past summer. It was received in a brief address by the President, Dr. Barker, on behalf of the Fellows of the Academy; and Dr. Wm. H. Draper then read a

Memoir of the late Willard Parker, M. D., LL. D.;

after which Dr. A. L. Ranney read a paper on

The therapeutical effects of the internal administration of hot water in the treatment of nervous diseases.

The tendency of the age, particularly in neurology, he thought, seemed to be to manifest itself in endeavors to discover new medicinal agents, often to the neglect of simple remedies whose influence upon the system had not yet been thoroughly tested. Among the latter, to his mind, hot water stood preëminently at the head. There was little or nothing in medical literature in regard to the physiological and therapeutical effects of this agent when administered internally; and whatever of originality there was due in regard to the subject belonged to Dr. J. H. Salisbury, who called attention to it as early as 1858.

Having spoken of the different effects of different degrees of heat, in general, when applied to living tissues, Dr. Ranney said that he believed that the benefits that resulted from the internal use of hot water were due, in part at least, if not wholly, to heat. He then gave the following rules for its administration.

I. The water may be taken in doses of from one goblet to one and a half. The dose must be modified in accordance with its effects.

II. It must be taken hot and not warm (from 110° F. 150° F.), and, if necessary, fifteen minutes or more may be consumed in sipping a gobletful. Wooden cups prevent the water from cooling quickly. If there is obstinate constipation, Carlsbad salts, or other laxative, may be added to the morning dose. No flavoring is as a rule required.

III. The dose must be taken one hour and a half before each meal, with absolute punctuality, and again at bed-time.

IV. The temperature of the water should be increased as fast as it can be borne.

V. The hot water must be kept up with great regularity for at least six months in order to get its full effects.

VI. The dose should be determined largely by the specific gravity and general character of the urine. The object of the treatment should be to bring the specific gravity to the standard of health (1.010 to 1.022). and to keep it there.

VII. The use of cold fluids, in the form of beverages, must be absolutely prohibited.

VIII. A restricted diet is often necessary to the full effects of the treatment in some forms of nervous derangements. The condition of the subject in respect to flesh is to be the guide, as a rule, to the character of the diet prescribed, provided that marked disturbances to digestion or diabetic symptoms are not to be combated. In some instances Dr. Ranney said he employed a meat diet exclusively.

He spoke next of the physiological effects of the internal use of hot water on the stomach, skin, kidneys, intestines, liver, and pancreas, and then related some of the cases in which he had employed it successfully. Among these were instances of neuralgia, insomnia, gastralgia and neurasthenia, and two cases each of locomotor ataxia and diabetes. Both of the latter he thought were of neurotic origin. The theory of its action he believed to be that of reflex irritation from the effect of heat upon the nerves of the stomach and the solar plexus. Having answered several objections which might perhaps be raised against the use of hot water, in conclusion he advised its thorough trial on the following grounds: —

I. It was harmless, if it did not benefit.

II. Its effects were comparatively uniform if its administration were kept up for a sufficient time.

III. It seemed to have the effect of arresting degenerative processes in certain cases of organic nervous disease.

IV. Its effects were apparently permanent.

V. It could be employed as an adjuvant to other treatment.

VI. It had a marked effect in relieving hyperæmia and anæmia of the nervous centres, and was useful in the treatment of headache, vertigo, and neuralgia.

VII. It was of great service in the treatment of diabetes and some kidney affections. It ordinarily had the effect of raising the quantity of urinary salts.

VIII. The functions of the accessory organs of digestion, the liver and pancreas, were stimulated by it.

IX. It stimulated the action of the skin, and rendered the cutaneous circulation uniform.

X. It was useful in the prevention of sea-sickness. When given for this purpose it should be prescribed for from four to six weeks before the commencement of an ocean voyage.

The paper was discussed by Drs Seguin, Amidon, Birdsall, Putzel, Dana, and Corning.

DR. SEGUIN thought that the temperature of the water must necessarily be greatly reduced by the time it reached the stomach, and that it was probably merely as a diluent that the agent acted, since he had obtained equally good results from the use of cold water, which he usually directed to be taken with the meals. The most of the cases to which Dr. Ranney had referred were probably such as were usually associated with malassimilation or lithæmia, and the fact that he had enjoined a restricted diet, in addition to the use of hot water, seemed to indicate that it was the digestive function that was primarily at fault; in further corroboration of which was the fact that he took the condition of the urine for his guide in regulating the amount of water to be used. As to the benefit to be derived from water, whether cold or hot, it had been pointed out several years ago by Dr. McElroy, of Zanesville, Ohio, that in cases of neurasthenia in females a lack of thirst was often a characteristic symptom; an observation which was afterwards fully corroborated by Dr. Webber, of Boston. Personally he could see no objection to the use of ice water, as he believed that the temperature of the fluid became considerably elevated by the time that it reached the stomach. He had had no experience whatever in the treatment of organic disease of the nervous system with hot water

DR. AMIDON thought that the fact which Dr. Ranney had stated, that the agent acted gradually, so that six months were often required for the substantial relief of the patient, went far to show that its modus operandi could not be that of a counter-irritant or derivative. This slow action seemed to indicate very strongly, he thought, that the benefit which was produced by it was due merely to its diluent qualities, as Dr. Seguin had suggested.

DR. PUTZEL could not understand how an agent which was supposed to be useful in cerebral hyperæmia could also be of service in cerebral anæmia, and also agreed with Drs. Seguin and Amidon that the hot water could not act by exciting reflex irritation. An irritant, he said, after a time ceased to be such, and if the hot water acted in this way the best results from its use could be seen at first. He did not see how this agent could have any effect in organic nervous disease, and believed that the recovery from diplopia under its use in the case of locomotor ataxia to which Dr. Ranney had referred was merely a coincidence.

DR. BIRDSALL wished that the paper had given more clear statistics. As it was the cases were of little value since other methods of treatment were always used in addition to the hot water. Thus in his cases of locomotor ataxia Dr. Ranney employed nitrate of silver, a remedy which was acknowledged to be of considerable value in this affection.

DR. SCOTT, of San Francisco, who was a guest of the Academy, referred to the great value of hot water in checking emesis, especially after the inhalation of ether.

DR. RANNEY, in closing the discussion, contended that the effect of hot water was very different from that of cold, and said that four goblets of the former taken during the day had a much more powerful diuretic effect than a gallon or more of cold water. As to his cases being rendered unsatisfactory by the fact that he had employed a special diet and other remedies in addition to the hot water, he would only say that notwithstanding the diet and the other remedies the patients did not improve until after the hot-water treatment had been commenced. It was a mistake to suppose, as many of the gentlemen who had spoken seemed to do, that this agent acted *only* in a very gradual manner. It was true that it sometimes took six months to secure the full effect of the remedy, as seen in the marked and permanent improvement in the nervous symptoms present, but in reality it had a very rapid action, the effect on the circulation of the skin and the kidneys being immediate. In regard to its action on the cerebral circulation, whether hyperæmia or anæmia were present, its tendency certainly was to restore it to its normal condition. Such was the fact, however the *modus operandi* might be explained. Dr. Ranney replied in the negative to a question as to whether he had ever noticed (1) a marked loss of the power of absorption and assimilation with rapid inanition, and (2) a tendency to internal hæmorrhage in those long accustomed to the internal use of hot water. These conditions he had himself seen more than once in patients at Saratoga, where he practiced during the summer, and the late Dr. F. D. Lente had observed the same thing.

Before the Academy adjourned DR. C. R. AGNEW called attention to

A NEW LOCAL ANÆSTHETIC,

the hydrochlorate of cocaine, to which reference had been made in a recent letter written from Germany to the *Medical Record* by Dr. H. D. Noyes, and which he had used with complete success in fifteen or sixteen operations upon the eyes during the past week. The form in which the drug was used was a two per cent. watery solution, which was dropped in the eye.

Recent Literature.

The Medical Graduate and His Needs. By GEORGE C. WELLNER, M. D. Detroit: George S. Davis. 1884.

This little book of primer proportions is designed by its author chiefly for students and young practitioners, but, he suggests, may be read with profit by "children of a larger growth." There is, undoubtedly, much that is wise and much that is true to be found in these pages, but less novelty of language, greater simplicity of style, a more careful revision of proofs, would make it more useful to readers for whom it is designed.

On page 24 we find "calamatous;" page 26, "to act the medical histrion," "derisive dread;" page 28,

"nothing is so well calculated to do this than the statement," etc., "the subject of misdiagnosis," "to misdiagnosticate a disease," "preadmonished;" page 30, "exertive efforts," "macaronic compounds," "medical abecedarian;" page 32, "the young physician should accustom himself to the use of the stethoscope, as there remains no longer an excuse for burrowing the side of one's face in the chest of the patient and thus, auscultation, circumscribe it;" page 66, "let him ween himself fortunate if the halcyon days of his sinecurism," etc., etc.

Medical and Surgical Journal.

THURSDAY, OCTOBER 16, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

INTERNATIONAL COLLECTIVE INVESTIGATION OF DISEASE.

IN a disjointed and unmethodical manner a quasi collective investigation of disease is always being carried on by hospital reports, by the published transactions of medical organizations, and by the meetings of societies and associations, but it has long been felt that more than this was not only desirable but possible.

Several earnest enthusiasts in England, among whom Professor Humphrey, of Cambridge, and Drs. Ransome and Mahomed deserve prominent mention, after agitating the subject in addresses and articles on various occasions, determined to attempt an organization for the prosecution of collective investigation on a large scale. The British Medical Association was appealed to at its meeting in Cambridge in 1880, the suggestion was favorably entertained, and a committee appointed to report a plan for carrying out such a work with the support of the Association's funds and *Journal*. In consequence a committee of seven, known as the Combined Observation Committee, with a secretary, has been annually appointed, and a thorough organization of branches ramifying through the Association been effected. The first issue of the *Collective Investigation Record* was published in July, 1883, and a second number this summer. Many of the best men in London and elsewhere have thrown themselves into the movement with a zeal and earnestness deserving of the highest praise, whatever the results accomplished.

We believe this JOURNAL was the first in this country to direct attention to the efforts being made by our British brethren, and we have watched with pleasure the growth and development of the movement. The subject was brought before the American Medical Association by Dr. J. S. Billings at its annual meeting in 1883, and referred to a committee, of which Dr. N. S. Davis, of Chicago, was appointed chairman. It was also brought last year before the Berlin Medical Society, referred to a committee upon which were Professor Frerichs, Drs. Fränzel, Ewald, Leyden, Löwenstein, and Börner, and an organization effected which is already at work. In other European countries attention has been attracted to what has been done in England and Germany, and the advisability of imitating their example has been under consideration.

To take advantage of and to encourage this growing interest in the subject of collective investigation for a unification and consolidation of aims and methods, the general meeting of the International Medical Congress, held at Copenhagen on August 14, 1884, upon propositions made by Sir James Paget, Professor Ewald, of Berlin, Professor Bouchard, of Paris, and Dr. Billings, of Washington, passed the following resolutions: —

(1.) That an International Committee be formed for the Collective Investigation of Disease in connection with the work of the International Medical Congress.

(2.) That the following gentlemen do represent their respective countries thereon: As representatives of Denmark, Professor Trier, of Copenhagen, Prof. C. Lange, of Copenhagen; Scandinavia, Dr. E. Bull, of Christiania; Russia, Dr. Rauchfuss, of St. Petersburg; Germany, Professor Ewald, of Berlin, Professor Bernhardt, of Berlin; Austria-Hungary, Professor Schnitzler, of Vienna, Professor Pribram, of Prague, Professor Korányi, of Buda-Pest; Switzerland, Professor D'Espine, of Geneva; France, Professor Bouchard, of Paris, Dr. Lépine, of Lyon; Great Britain and Ireland, Sir William W. Gull, Bart., Professor Humphrey, of Cambridge, Dr. Mahomed, of London; British India, Sir Joseph Fayrer, K. C. S. I.; United States, Professor Jacobi, of New York, Prof. N. S. Davis, of Chicago; South America, Dr. Gutiérrez-Ponce, of Paris. As Secretary-General, Dr. Isambard Owen, of London.

At the same time the Secretary was instructed to prepare a statement as to the objects of the committee for translation and publication in the medical journals of the various countries represented. A copy of this statement will be found in full on another page of this issue of the JOURNAL.

Having always warmly approved of the project for collective investigation of disease since its first inception in England, we gladly give publicity to this attempt at an international extension of the same, commending it to the thoughtful attention of our readers.

We cannot sympathize with those who sneer at or discourage any earnest disinterested efforts to promote coöperation in the advancement of medical knowledge and the promotion of our art to the dignity of a science, however great the task, however inadequate the means, however certain the failures and disappointments. But the present movement, both abroad and at home, starts out under no mean auspices, and if supported elsewhere with the same energy as has been manifested by its early promoters cannot fail of greatly advancing medicine and the medical profession.

Mistakes will undoubtedly be made, and much chaff will doubtless be gathered along with the grain; but the mistakes may themselves be fruitful for instruction, and the separation of the chaff from the wheat be turned to profit. The work of medical men, as a rule, is necessarily too isolated and solitary, and the majority of men in active practice have neither the opportunity nor the stimulus for comparison and collaboration of methods and results before any other tribunal than that least qualified of all, — the general public. Men who now think they have no time to record their cases may be quickened; those who do not know how may be assisted by forms and taught by the merits and defects of others. To some it occurs to observe things not presented to others, or to see what others overlook. Different interpretations may be put upon the same fact by different observers. The same diseases in different countries present themselves under different guises, as modified by climate, by race, by customs. A simplification and unification of nomenclature of disease, as of weights and measures, would be a not impossible outcome of a vigorous and successful prosecution of the present movement.

We are by no means blind to the difficulties or sources of failure involved in a national or international collective investigation of disease; but no faint heart ever yet won a fair lady, nor have the so-called impregnable positions been carried by folding the hands and reciting a list of the obstacles and previous failures.

"PRACTICAL RECOMMENDATIONS FOR THE EXCLUSION AND PREVENTION OF CHOLERA."

AMONG our Society reports this week is to be found quite a full account of the Conference of State Boards of Health held at St. Louis last week, simultaneously with the meeting of the American Public Health Association. This is the second annual conference of our State Boards of Health, and it was understood that the special subject of the occasion would be the drafting of recommendations for practical steps to be taken by national and local authorities to prevent the introduction and dissemination of cholera in this country in view of its prevalence in Europe.

The question is such a vital one, and the part to be acted by these State Boards, should the country be brought to face it in earnest, is so important, that we have not grudged the space which the report occupies, and have given the recommendations and suggestions finally adopted by the Conference and accepted by the Public Health Association, without abbreviation.

The representatives of interior States and of those on the seaboard necessarily take somewhat different views of the value of quarantine and of the relative reliance to be placed upon external and internal quarantine. There appears in the recommendations adopted a desire to harmonize conflicting views, and to secure the coöperation of all concerned.

There will always be the inclination to place the responsibility for the introduction of a disastrous epidemic at some remote point, and upon some one else's shortcomings. States situated in the Mississippi Valley feel that New Orleans should protect them from and not furnish them with yellow fever. Illinois is, naturally, aggrieved if New York and Boston send unvaccinated immigrants, with small-pox contagion among them, by through trains to her borders. In some degree in these matters there is cause for complaint, in some degree fear and feeling and an unwillingness to put things to rights at home have at times usurped the place of reason and judgment.

If external quarantine could exclude cholera from a country it would offer a comparatively simple solution of a great difficulty; but it never has and never will do so. Much may be done by inspection and disinfection of passengers, of their effects, which, notwithstanding Dr. Rauch's individual experience, are dangerous, of their transports (not of cargoes); but even in this, more reliance must be placed upon the intelligent judgment and good sense of trained inspectors than upon any rigid regulations. A cut-and-dried external quarantine, whether long or short, is and has been over and over again proved to be worse than useless. It is always sieve-like and is repulsive to the intimate and intricate commercial relations of the present day. Italy and Spain have just furnished fresh illustrations — if such were needed — of its worthlessness. Moreover, reliance is placed upon quarantine just in so far as communities are conscious of their own sanitary deficiencies; and conversely just in so far as reliance is placed on quarantine are communities negligent about local sanitation.

When it comes to internal quarantine and *cordons sanitaires* no language is too strong to describe their folly, and we heartily sympathize with the position taken at the Conference by Drs. Chancellor and Holt upon this point, though we protest against the statements of the former as to the diffusion of the cholera poison through the atmosphere.

A good water supply, good drainage, wholesome living, a tranquil spirit, these are the true safeguards against cholera preëminently, as against sundry other epidemic disorders in a lesser degree. These are the agents dreaded by microbes with pathological tendencies, whether presenting themselves in the bacillar or the spirillar forms, or as hybrids with comma-like extremities.

THE TICHBORNE CASE AND MEDICAL EVIDENCE.

THE release of the Tichborne claimant from prison after the expiration of ten of the fourteen years of his penal sentence marks the conclusion of another stage of this *cause célèbre* which has lessons of importance regarding the value of evidence in medico-legal questions.

The main features in this case are doubtless familiar to our readers. Roger Tichborne, an eccentric and not over intelligent young man of twenty-six years, left England in April, 1854, for a foreign tour. The vessel on which he sailed was said to be lost with all

on board. Lady Tichborne, the mother, refused to believe that her son was dead, and after twelve years of advertising for information of Roger a claimant of the name appeared in England with his wife and child, was seen and recognized by numerous attachés of the Tichborne estate as the missing man, and went to Paris, where he was unhesitatingly recognized by the old lady as her missing son, and so announced at the British embassy. The claimant was given a liberal allowance by his supposed mother, who continued to live with him with great comfort to herself till the day of her death, which happened in March, 1867. Other members of the family, however, considered him an impostor. He laid claim in 1871 to the estates, valued at £25,000 a year. This caused the first of the two memorable suits. In this action dozens of persons swore definitely to his identity with Roger Tichborne, and as many testified with equal positiveness to his not being that individual, some of them saying, moreover, that he was one Arthur Orton, a butcher of Wapping, who had been an associate of the lost Roger, and had gone, at about the same time with the latter, to Australia. After a trial lasting over a hundred days the plaintiff was nonsuited, and was then at once arrested for perjury and forgery. His friends and supporters, who were many, and who had contributed liberally towards the expenses of the suit, now furnished bail, and the trial came on in 1872 before Lord Chief Justice Cockburn and two other justices. This trial lasted 190 days, and is said to have cost the government no less than £300,000.

The theory of the prosecution was that the claimant was not Sir Roger but Arthur Orton. For the defense 132 persons made oath distinctly that the claimant was Tichborne. Of these 110 swore that Tichborne as they knew him before 1854 had dark-brown hair; thirty-seven swore that he had small hands; thirty-five that he had small feet; seventy-nine that he had an "in-turned knee"; eighty that he had a twitching of the eyebrows, and thirty-four that he had no marks of small-pox. The claimant had dark hair, small hands and feet, an "in-turned knee," twitching eyebrows, and no pock-marks. Seventy-five witnesses were then called who had known Arthur Orton, who all testified that he had light hair (in which they were supported by eleven government witnesses); sixty swore that he had large hands; fifty-two that he had large feet; fifty-one that he had high cheek bones; seven that he had light blue eyes; and twenty-eight that he had marks of small-pox. There was, however, enough opposing evidence to convince the jury that the claimant was no other than Arthur Orton; and he was found guilty, as charged, of perjury and forgery, and was sentenced seven years for each offense. The term was shortened a quarter for good behavior as is customary, and he has served ten years.

Meantime the friends of the claimant set to work to prove that he was not Arthur Orton, and they claim to have now established these facts: That Arthur Orton lived in Australia under an assumed name by which he was traced with difficulty; that under the name Cresswell he married a widow, whom he told the day after his marriage that his real name was Arthur Orton, of Wapping: that Orton drank to excess and became insane; and that he is now in a lunatic asylum under the name of Cresswell; that two brothers of Arthur Orton who went to Australia for the purpose of seeing this individual unqualifiedly pronounced him to be their brother; that he in turn recognized them and called them by name in the presence of the asylum officials; that eighteen independent witnesses have testified to his identity with Arthur Orton; and finally, that the story told by this lunatic of the Tichborne claimant confirms the testimony of the latter regarding the true Orton.

The fact that the case has already been before the highest court in England may make a reopening of it impossible, even supposing this new evidence to be confirmed. But the fact which at present alone concerns us is that so very many witnesses in this case, from first to last, have sworn, and, presumably, with honesty, directly against each other. If the claimant is a fraud there is no ground for supposing that any considerable number of his witnesses are willful perjurers. Though, perhaps, a majority of the public acquiesced in the justice of the decision in these trials, yet a great number of individuals are still convinced that the claimant was wronged. The unreliability of much of the testimony to identity in the courts generally has been abundantly illustrated. Particularly in the case of dead bodies mistakes are constantly made, so that the possession of some visible deformity or other marked peculiarity is almost necessary to gain credence for necroptic identification. Every wholesale drowning or burning accident gives fresh proof of this. Points turning upon the mistaken identity of the living are frequent enough in every court record. But it is not often one sees such wholesale error as must have been made by one party or the other in the Tichborne case. It is a wise parent that knows her own child, yet in face of the testimony of the brothers and sisters and against the verdict we have the affidavit of the dowager Lady Tichborne (who was only prevented by death from giving her evidence in court), "I am as certain as I am of my own existence, and distinctly and positively swear that the plaintiff is my first-born son, the issue of my marriage with Sir James Francis Doughty Tichborne."

Finally, reproach is brought, and with some reason, against the widely variant testimony of different medical experts in any given case. Yet their disputes have often regard to matters of opinion, or if to facts, yet to facts requiring the most skilled and careful scrutiny for their proper observation. But in this great case hundreds of witnesses testified diversely as to the most obvious facts, such as the color of the hair, the presence of pock-marks. A few years' and even a few months' lapse plays great havoc with men's memories. The discrepancies in expert testimony are not to be too hastily ascribed to the bias of lucre. Imperfectness of observation accompanied by dogmatism of assertion is proved by such cases as the Tichborne trial to be but too common in every class, and though scientific training tends to free a man from

both these faults, yet there is enough of them left in average human nature to cause mischief in the investigation of difficult questions of fact or abstruse ones of opinion.

MEDICAL NOTES.

— Dr. Schweninger, of somewhat questionable repute, the medical attendant of Prince Bismarck, has been by distinguished influence foisted into the Berlin Medical Faculty. This body has had the spirit to make a protest against the appointment as unfit, but with what result remains to be seen. The premier's favorite was also made a member of the German Sanitary Board without any qualification for the post whatever, and against the protest of the director. Dr. Struck (also formerly a medical attendant on Prince Bismarck), who, in consequence, resigned his post. Dr. Koch has also, on account of some unpleasant circumstances connected with the affair, given up his seat on the Board, after having declined to be nominated as Struck's successor. It is to be feared that a conflict of this sort will be a terribly one-sided affair, but no other course seems compatible with the self-respect of the profession.

— Dr. Richardson has been making some successful experiments for the painless extinction of animal life. The electric shock did not prove sufficiently safe, says *Science*, so Dr. Richardson sought for an anæsthetic agent which would make death rapid as well as painless. He successively experimented with nitrous and carbonic oxides, ether, chloroform, coal-gas combined with chloroform, all of which more or less fulfilled their end. The results have been very satisfactory as carried out at the London home for lost dogs, where a chamber was charged with carbonic oxide, the gas having been previously passed over a porous surface, from which it took up vapor containing chloroform. Into this chamber was introduced a cage containing the dogs, which in a very short time passed from life to death in a profound sleep, without evincing the slightest pain or consciousness. Dr. Richardson has also administered the same narcotizing agent to sheep, so as to allow of their being killed in a perfectly painless manner; and he hopes that before long there will not be an abattoir in England without facilities for employing the system.

NEW YORK.

— The first annual meeting of the New York State Medical Association will be held at the new Murray Hill Hotel, on Park Avenue, on the 18th, 19th, and 20th of November. The annual address will be delivered by the president, Dr. Henry D. Didama, of Syracuse, the address on Surgery by Dr. E. M. Moore, of Rochester, the address on Obstetrics and Gynæcology by Dr. T. Gaillard Thomas, and the address on Medicinal and Non-Medicinal Therapeutics by Dr. Austin Flint, Sr. Among the papers to be read are the following: A New Procedure in Paracentesis Thoracis, by Dr. Thomas F. Rochester, of Erie County; A Case of Tubal Pregnancy, by Dr. Nathan Bozeman, of New York; Insanity: Preventive Measures, by Dr. John P. Gray, Superintendent of the State Lunatic Asylum at Utica; Excision of the Knee in Preference to Amputation in certain Deformities of the Leg, by Dr. Stephen Smith, of New York; Some Points in the Management of Breech Cases, by Dr. William T. Lusk, of New York; Abscess of the Liver, by Dr. E. G. Janeway, of New York; Diphtheritic Croup, by Dr. J. Lewis Smith, of New York; Typical Cases of Diabetes Mellitus not before reported, by Dr. A. Flint, Jr., of New York; and Report of a Case of Ligature of the Primitive Iliac Artery for Diffuse Aneurism of the External Iliac Artery, by Dr. J. W. S. Gouley, of New York. On the evening of November 20th the Fellows residing in New York County will entertain the Association at a banquet in the south grand hall of the Murray Hill Hotel, and on the morning of the 21st there will be surgical operations in the amphitheatre of Bellevue Hospital, followed by a demonstration of the application of the plaster-of-Paris jacket in the treatment of spondylitis and lateral curvature of the spine, by Dr. Lewis A. Sayre, after which an excursion will be made to the hospitals and other institutions on Blackwell's, Ward's and Randall's Islands under the charge of the Commissioners of Charities and Correction.

— On the 4th of September a boy ten years of age, who had been bitten by a Spitz dog in July, died of hydrophobia under the care of Dr. J. R. Cypert.

— Mr. Henry Lamb, of Rochester, has given $2000 to be distributed in prizes for essays on sanitary topics, and at the Public Health Convention in St. Louis last week the committee having the matter in charge reported that $500 would be awarded for the best paper on each of the following subjects: Healthy Houses and Food for the Working Classes; The Sanitary Condition and Necessities of School-Houses and School-Life; Disinfectants, and an Individual Prophylactic Agent for Infectious Diseases; and Appliances and Means for Saving Life and for Protection against the Injurious Influences of Certain Work and Occupations on Health. All competing essays must be sent in by April 1, 1885. At this meeting Dr. A. N. Bell, of Brooklyn, read the report of the Committee on Epidemics, in which it was claimed that in New York and other large cities epidemics had repeatedly been satisfactorily controlled by the observance of strict sanitary precautions.

On the 22d of October an open competitive examination, under the New York State Civil Service rules, was held at the New York Academy of Medicine to fill vacancies in the regular medical staff of the Hudson River State Hospital for the Insane at Poughkeepsie, for the positions of first assistant physician at an annual salary of $3000 and board, and third assistant physician at an annual salary of $1000 and board. The subjects on which the examination was made were of two classes, general and medical, and those comprised in the latter were the following: *Obligatory.* Theory and practice of medicine, therapeutics, clinical medicine, anatomy, physiology, and pathology of the brain, and psychological medicine. *Optional.* Use of

the microscope and instruments of precision, medical chemistry, sanitary science, special branches of medicine, experience in the care and treatment of the insane, and experience in the management of institutions for the insane.

— At a meeting of the trustees of the College of Physicians and Surgeons, held on Saturday evening, October 18, it was officially announced that Mr. Wm. H. Vanderbilt had given to that institution, as a building fund, the sum of $500,000, which is probably the most munificent donation ever made to a medical school. It is stated that a site, including twenty-nine city lots, on Tenth Avenue, between Sixty-eighth and Sixty-ninth Streets, has already been secured, and that building operations will soon be commenced. This location is in the vicinity of the Roosevelt Hospital, but is remote from the large public hospitals, Bellevue and Charity.

Correspondence.

"DIPHTHERIA SPREAD BY ADULTS."

Plattsburg, N. Y., *October* 13, 1884.

Mr. Editor, — The article in your issue of the 9th inst. entitled, "Diphtheria Spread by Adults," ought not to pass by without a protest or at least some form of a denial. Dr. A. Jacobi's views on diphtheria, according to that article, are full of vagaries and contrary to clinical facts. The chief harm that can come from them is that some people *may* believe them. If this, his "cannon ball," be accurately aimed, there would be nothing left for the "pistol bullet" to destroy. In the first place there is no reasonable doubt that diphtheria is contagious. That it is invariably so has not yet been proved, and probably never will be. The isolated, solitary cases often appearing in the country, in which no possible source of contagion can be traced after careful investigation, are pretty good evidence that diphtheria may, in some instances, have a spontaneous origin.

In the second place, "what has been called follicular tonsillitis is" *not* "mostly diphtheria." There are cases of sore throat so mild and so peculiar that it is difficult to decide positively what their true character is. But these cases are so few that they do not constitute even a *respectable* minority.

In the third place it is very far from the truth that "There is as much diphtheria out of bed as in bed; nearly as much out of doors as in doors." Of course it is probable that some of Dr. Jacobi's "mild cases of diphtheria" which "have continued six or even nine months" may be out of doors before complete recovery. No one denies that all reasonable precautions should be taken to prevent the spreading of this terrible disease. The "nares and throats of all attendants and help" should be examined. So also "the sick nurses, the cooks, teachers, hair-dressers, and barbers, shopkeepers and restaurant keepers" should be looked after. But why stop here? Why not station special examiners on all street corners, in all railroad stations, at all country cross roads, and in numerous other places, so that those "who are in constant contact with all classes and ages," and especially those "who are out of bed and out of doors" may be kept from a possibility of spreading any possibly contagious disease? Perhaps some labor-saving machine could be invented and used that would facilitate these examinations.

Yours truly, D. S. Kellogg, M. D.

Miscellany.

THE FOLLIES OF QUARANTINE.

The *British Medical Journal* (October 4th) discourses forcibly, and in the same vein as our own editorial of September 25th, on the uselessness of the cordons by land and sea which have been substituted by the cholera-threatened cities of Southern Europe for the cleansing and disinfection of their own filthiness, which alone can check the epidemic. It says that the medical profession in France and Italy, as a body, has disapproved of these measures, following the opinion of German sanitarians, as expressed by Virchow, that the experiences of 1830 exploded all confidence in such cordons.

"In the *Annales d'Hygiène Publique*," continues the *Journal*, "that able French sanitarian Dr. Du Claux has recently lodged a complaint against the violent and vexatious measures of quarantine leveled by Italy and Spain against France. Not content, he says, with imposing ten days' quarantine at all their ports, they have established a useless land quarantine on the frontier; every pass in the Alps and Pyrenees is guarded with patrols, and travelers are crowded into filthy lazarets for seven days. Quoting from the *Temps*, he shows that prohibitive measures in Italy were from the first day pushed to absurd extremes. The papal Nuncio remains at Paris unable to pass the frontier. The French Ambassador is there too, for to reach the Quirinal he must pass eight days in the barracks of Bardonnechia, and risk being shot at by peasants and sentinels if he dares even to look over the walls. The lazarets of Italy have been crowded with 7000 miserable inhabitants; none of them, strangely enough, have been seized with cholera; yet, with all these vain, obstructive, and vexatious precautions, cholera has broken out more severely in Naples than elsewhere. In Spain the lazarets are filled to overflowing; it is not merely a question of spending seven days in them, the traveler has to wait a week for the chance of it.

"But Dr. Du Claux does not only inveigh against the follies of Italy and Spain. He strongly condemns as impracticable the attempt to put a *cordon* about Toulon. 'My humble opinion,' he adds, 'is that if the gates of Toulon had been shut the inhabitants would have passed under its walls.' It would, indeed, be difficult for any sanitarian to justify the acts of folly that have been committed through panic in France. Though it was well known that within ten days from the first outbreak two thirds of the inhabitants of Toulon and Marseilles had fled from their cities, many of them to Paris, which has remained singularly free from the epidemic, yet, at Lyons, every passenger from the south continues to undergo a mysterious rite. For a quarter of an hour a spray of carbolate of soda is played upon him, and then he is allowed to go free. In other towns the hapless visitor is shut in a room with sulphur heaped on live coals. Those of us who have seen cholera, and those who heard Dr. Norman Chevers tell us at the recent Social Science meeting at Birmingham that, during thirty years' experience in

India, he had never seen a single case of contagion, may smile at these simple attempts to destroy bacilli which, if anywhere, are deep in the intestinal canal, but those who have experienced these fumigations cannot smile. English invalids have received a scare that will be difficult to overcome. They might take their chance of cholera, but the lazarets and fumigations are intolerable. In truth each nation appears to distrust the other. Reprisal quarantine has reached its climax, commerce is deplorably disorganized, and the absurdity of the triangular duel between France, Italy, and Spain is admitted almost as openly by the sanitarians of these nations as by the English and Germans.

"Meanwhile, in England, there has been neither cholera nor panic of cholera, and there has been no disturbance of commerce. When one cholera ship from Marseilles arrived at Cardiff, and another at Liverpool, the measures taken by the Local Government Board were amply sufficient to prevent any outbreak. With us, quarantine, whether by land or sea, is wholly discredited. Any vessel may discharge its cargo at any port. Of course if there be cholera on board, there is a medical supervision of the sick man; but the destruction of cargoes and detention in lazarets, which is universal in the Mediterranean ports, is here unknown. Of land quarantine, English sanitarians have really no personal experience. It is known to have failed in India, and it has been rejected as useless in Germany. But no nation has so much evidence of the inutility of port quarantine; and whenever an international conference may be called we shall be ready with proof that cholera is but rarely carried in ships; that, as Von Pettenkofer insists, it dies away after a fortnight's voyage; and that medical supervision of the sick, together with adequate sanitation, are the best methods for preventing an epidemic. M. Clemenceau says it would be more easy to revise the Constitution than to cleanse Toulon; yet it is a task to which the inhabitants must ultimately devote themselves if they would keep out cholera."

STATEMENT RELATING TO THE INTERNATIONAL COLLECTIVE INVESTIGATION OF DISEASE, PROPOSED AT THE INTERNATIONAL MEDICAL CONGRESS AT COPENHAGEN.

THE main objects which the Committee seeks to attain through the Collective Investigation of Disease are to widen the basis of medical science, to gather and store the mass of information that at present goes to waste, to verify or correct existing opinions, to discover laws where now only irregularity is perceived, to amplify our knowledge of rare affections, and to ascertain such points as the geographical distribution of diseases and their modifications in different districts. It will be its endeavor to place clearly before the whole profession the limits and defects of existing knowledge, as well as to stimulate observation, and to give it a definite direction. It will be a not unimportant incidental result of its work should it tend, as is hoped, to the better training of the members of the profession in habits of scientific and practical observation, and in systematic methods of recording the facts which they observe.

The age in which we live has seen enormous advances in the sciences on which the fabric of medicine rests, such as Chemistry and other branches of Physics, Physiology, and Pathology. Each of these has taken giant strides. It must be admitted, however, that purely medical knowledge has scarcely made proportionate progress. It cannot be expected that it should do so, as it deals with the aberrations of the most complex of organisms, is of all sciences the most difficult, and demands the greatest patience and the largest accumulation of data.

Hitherto the advancement of medical science has been brought about mainly by individual effort. The value of such work in the past we in no way underrate, nor do we desire to lessen the amount of it in the future; but in medical science there is much that defies interpretation from individual experience, and many problems so far-reaching in an ever-widening field, with elements so manifold, that no single man, however gifted and long-lived, can hope to bring the whole within his range. The need, therefore, in medicine, of that combination and concentration of individual work which is adopted in many other branches of science and in commerce, and to which increasing facilities of intercommunication have given so much impulse and so much strength, cannot be questioned. Indeed, it may be said that, resting on individual research alone, medical knowledge can be advanced but slowly and with difficulty. Future progress to any great extent must be the work, not of units acting disconnectedly, but of the collected force of many acting as one. For many to act as one, organization is needed; that organization it is the purpose of our Committee to supply.

Disease is many-sided, and we wish to include in our organization those who see it from every side. All, therefore, whether hospital physicians, family and school attendants, specialists, medical officers of the army and navy, and of workhouses and asylums, will be asked to contribute their quota of observation to the common fund.

In England and in Germany organizations for this purpose already exist, through which good work has been accomplished, and a volume entitled the Collective Investigation Record, containing tabulated returns, with reports upon them and other matter, is published annually by the British Medical Association. France and Austria are alive to the importance of the new method. In Scandinavia and in the United States the foundations of associations have been laid. Denmark, Russia, and Switzerland are setting their hands to the task. To unite these several associations by an international organization for the study of various problems, and to induce the formation of similar combinations elsewhere is felt to be a work peculiarly befitting an international congress. Our Committee is enjoined by the Congress at Copenhagen to endeavor to carry out this work, and in compliance with that injunction it invites the coöperation of all who have at heart the promotion of medical science and practice.

The following is the proposed method: A subject having been selected, a person or persons of acknowledged authority will be asked to write a memorandum, in the form of a short essay, upon it. The memorandum will succinctly give the present state of our knowledge. It will also point out the directions in which further research may best be made, and with this view will suggest a few simple and definite questions upon the subject selected. The questions will relate to matters of fact, to be elicited by observation of cases, rather than to matters of opinion.

The contemplated organization will, it is hoped, in time enable the committee to ask and collect answers to these questions from the profession at large wherever scientific medicine is studied or practiced. It will be a further duty to examine, arrange, tabulate, and deduce results from the mass of observations thus collected, due credit being given to each contributor for the information he has furnished, and reports on the results of the several investigations will be laid before the International Congress at its next meeting at Washington.

ISAMBARD OWEN, *Secretary-General.*

5 HERTFORD STREET, MAYFAIR, LONDON.

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 11, 1884.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2283 (no reports from Brooklyn, New Orleans, and Buffalo): under five years of age, 927; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 613, consumption 313, diarrhœal diseases 254, lung diseases 176, diphtheria and croup 149, typhoid fever 86, malarial fevers 53, whooping-cough 24, cerebro-spinal meningitis 12, scarlet fever 24, measles seven, puerperal fever two. From *malarial fevers*, New York 16, St. Louis eight, District of Columbia and Charleston seven each, Baltimore five, Philadelphia and Chicago four each, Nashville two. From *whooping-cough*, New York 10, Boston four, Chicago and Baltimore two each, St. Louis, Cincinnati, Providence, New Haven, Worcester, and Lawrence one each. From *scarlet fever*, New York and Philadelphia five each, Boston and Baltimore four each, St. Louis, District of Columbia, Milwaukee, Worcester, Chelsea, and Merrimac one each. From *cerebro-spinal meningitis*, New York three, Philadelphia two, Boston, Milwaukee, Lowell, Worcester, Fall River, Newton, and Brockton one each. From *measles*, New York six, Cincinnati one. From *puerperal fever*, Boston and Milwaukee one each.

Cases reported in Boston: typhoid fever 69, scarlatina 63, diphtheria 30, and measles two.

In 104 cities and towns of Massachusetts, with an estimated population of 1,326,946 (estimated population of the State 1,955,104), the total death-rate for the week was 17.84 against 18.58 and 23.01 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending September 27th, the death-rate was 19.1. Deaths reported 3200: infants under one year of age 954; acute diseases of the respiratory organs (London) 162, diarrhœal diseases 354, scarlet fever 67, fever 63, measles 48, whooping-cough 42, diphtheria 24, small-pox (London 10, Liverpool, Sheffield, and Sunderland one each) 13. The death-rates ranged from 14.4 in Norwich to 28.8 in Preston; Birmingham 18.2; Blackburn 26.9; Bradford 22.7; Leeds 24.2; Leicester 21.6; Liverpool 25.1; London 16.1; Manchester 25.1; Nottingham 18.3; Sheffield 21.9. In Edinburgh 19.5; Glasgow 24.9; Dublin 30.2.

For the week ending September 20th, in the Swiss cities, there were 16 deaths from consumption; diarrhœal diseases 13, typhoid fever five, lung diseases four, measles, scarlet fever, and diphtheria each one. The death-rates were, at Geneva 6.1; Zurich 7.9; Basle 7.0; Berne 22.2.

The meteorological record for the week ending October 11th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY FROM OCTOBER 11, 1884, TO OCTOBER 17, 1884.

NORRIS, BASIL. lieutenant-colonel and surgeon. Relieved from duty as attending surgeon, Washington, D. C., and ordered for duty as medical director, Division of the Pacific, and Department of California, relieving Surgeon E. I. Baily. Colonel Baily, on being relieved, will assume the duties of attending surgeon at San Francisco, Cal.

SPENCER, WM. C., major and surgeon. From Department of Dakota to Department of the East.

GODDARD, CHARLES E., major and surgeon. To be relieved from duty at Jefferson Barracks, Mo., and to report for duty in Department of Dakota.

MCCLELLAN, ELY, major and surgeon. From Department of the East to duty at Cavalry Depot, Jefferson Barracks, Mo. S. O. 242, A. G. O., October 15, 1884.

MCKEE, JAS. C., major and surgeon. Granted leave of absence for one month, with permission to apply at Division headquarters for one month's extension. Paragraph 1, S. O. 149, Department of California, October 3, 1884.

LORING, LEONARD Y., captain and assistant surgeon. From Department of the East to Department of California.

HARVEY, PHILIP F., captain and assistant surgeon. From Department of Dakota to duty in attending surgeon's office, Washington, D. C., relieving

SHUFELDT ROBERT W., captain and assistant surgeon, who, on being relieved, will report to commanding general, Department of Missouri, for duty. S. O. 237, A. G. O., October 9, 1884.

PORTER, J. Y., captain and assistant surgeon. Granted leave of absence for one month on surgeon's certificate of disability, with permission to leave the limits of the Department. Paragraph 3, S. O. 138, headquarters Department of Texas, October 9, 1884. Confirms telegraphic order of same date.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING OCTOBER 18, 1884.

BRUSH, GEO. R., surgeon. To temporary duty at the Naval Laboratory. October 11, 1884.

BURBANK, CHARLES H., medical inspector. Detached from the Brooklyn, and placed on waiting orders. October 15, 1884.

CLARK, JOHN H., surgeon. Detached from the Lackawanna and detailed as Fleet Surgeon of the Pacific Station. October 17, 1884.

COOKE, GEORGE L., surgeon. To the Lackawanna. October 17, 1884.

EDGAR, JOHN M., passed assistant surgeon. To the Receiving Ship Franklin. October —, 1884.

HUDSON, A., medical inspector. Detached from the Lancaster and placed on waiting orders. October 14, 1884.

HUGG, JOSEPH, surgeon. Placed on waiting orders. October 13, 1884.

LOVERING, P. A., passed assistant surgeon. Detached from the Lackawanna and placed on waiting orders. October 17, 1884.

MARSTELLER, E. H., passed assistant surgeon. Detached from the Monongahela and ordered to the Lackawanna. October 17, 1884.

MARTIN, WILLIAM, assistant surgeon. Detached from the Passaic and placed on waiting orders. October 14, 1884.

MARTIN, H. M., passed assistant surgeon. Detached from the Brooklyn and placed on waiting orders.

AMERICAN ACADEMY OF MEDICINE. — The ninth annual meeting of the American Academy of Medicine will be held in Hopkins Hall, Johns Hopkins University, Baltimore, Maryland, Tuesday and Wednesday, October 28 and 29, 1884. Papers will be read by Drs. Peter D. Keyser, of Philadelphia, Penn.; Edward Jackson, of Philadelphia; Henry O. Marcy, of Boston; Albert H. Gihon, United States Navy; A. D. Rockwell, of New York; Benjamin Lee, of Philadelphia, Penn., President; R. Stansbury Sutton, of Pittsburg, Penn.; Virgil P. Gibney, of New York, N. Y.; Charles C. Bombaugh, of Baltimore, Md.; T. M. Ludlow Chrystie, of New York, N. Y.; Nathan Allen, of Lowell, Mass.; Herman Knapp, of New York, N. Y.; L. Duncan Bulkley, of New York, N. Y.; Richard J. Dunglison, of Philadelphia, Penn., and H. O. Marcy, of Boston, Mass.

TUMORS OF THE MALE BLADDER, WITH REPORT OF A CASE.[1]

BY DR. WATSON.

December 14th. The patient, aged sixty, has had a good family and personal history; has never had any illnesses of importance; has been free from any trouble of the genito-urinary tract until six years ago. At that time he passed by the urethra two small calculi without pain, and has passed none since. Shortly afterward began hæmaturia, slight in degree, the urine being more or less pink or red from the presence of blood uniformly diffused through it, and small blood clots being also occasionally present. This condition was constant, and has persisted ever since, varying, however, in intensity. The patient's health has not suffered until recently, nor has he had any other symptoms accompanying the condition until two months ago. Then began frequent and painful micturition, most marked at night. The frequency varied from three to six times during the night; in the day-time it was often normal. The pain was most noticeable before and during the act of micturition. The quantity of blood began to increase, and there were more clots. These symptoms were not augmented in severity by any kind of motion, being often worst at night when at rest.

The patient was a large, muscular man, and when first seen paleness, thinness, and a slightly yellow tinge of the skin were the only outward signs of disease.

A careful examination of the thoracic and abdominal organs gave negative results. Rectal examination showed that there was no prostatic enlargement. The bladder wall gave the impression of being slightly thickened and more resistant than normal. Nothing unusual could be detected by bimanual palpation of the bladder, and there were no enlarged glands to be felt in its neighborhood either while examining by rectum or otherwise. Palpation over the region of the kidneys, anteriorly and posteriorly, and along the course of the ureters showed nothing abnormal.

The pulse was fairly strong, the tongue clean. The patient had felt well enough to pursue his usual avocations until a day or two previous to my first visit, which was on December 14th.

From this time until the diagnosis was established the urine was frequently examined by me, and also by Dr. Gannett, and upon these examinations the diagnosis was made. Their results, though varying more or less, presented in the main the same important features, which may be embodied under one heading, as follows: —

Urine. Color, reddish-yellow, the degree and intensity of the red varying, but always present, and always arising from the admixture of fresh blood. Specific gravity 1013 to 1020. Reaction strongly acid. Odor normal. Urea, uric acid, chlorides, sulphates, earthy phosphates, alkaline phosphates generally normal. Albumen, about one eighth per cent., but varying with and corresponding to the quantity of blood present. Sediment large. On settling the supernatant fluid is still red. The sediment contained blood clots, whose shape, color, and consistency presented the characters of the clots of fresh hæmorrhage. The sediment also occasionally contained small bits of tissue having a fleshy appearance. Besides these constituents were found fresh red blood corpuscles, leucocytes, and polymorphous cells in the greatest variety, many of which had very large nuclei, physalids, bacteria, and granular matter.

During the act of micturition the blood though present in the first was most conspicuous in the last part of the stream, the few final drops being sometimes pure blood.

The treatment during the first days was chiefly expectant.

Ten days after first visiting the patient he had an attack of retention of urine, due to profuse hæmorrhage, clots plugging the orifice of the bladder so as to prevent the natural escape of urine. The bladder was distended, its fundus reaching half way to the umbilicus. The retention was complete for twenty-four hours, during which the pain and vesical tenesmus were treated, in my temporary absence, by subcutaneous injections of morphia. At the end of this time the urine began to flow occasionally in small quantities, and on my return I found the bladder, though still considerably distended, much diminished in size. At the end of the next twenty-four hours the flow of urine was fully reëstablished. Nausea and loss of appetite occurred with the attack of retention, and persisted for several days, during which time there was also polyuria, the largest quantity in twenty-four hours being 2900 cubic centimetres.

Coincident with this attack began pain in the sciatic region of the left side, which was severe, and which lasted more or less persistently for some weeks, confining the patient to bed.

A week later, with Dr. C. B. Porter in consultation, the patient was etherized, and the bladder sounded. Its antero-posterior diameter was four inches, and its capacity large. Five hundred cubic centimetres of *residual* urine were present. This quantity was thought to be due, probably, to the attack of retention and consequent over-distention of the bladder. No stone was detected. The extremity of the sound in sweeping the vesical cavity revealed to the touch nothing abnormal. Examination of the bladder wall (so far as it could be reached) between one finger in the rectum and the sound in the bladder gave only the impression of slight thickening. The sound was then withdrawn, and the bladder washed out through a soft catheter with water at the temperature of 114° F., and with Sir Henry Thompson's borax solution.

After recovering from the ether the frequency of the desire to micturate was less. A slight rise of temperature followed the examination, and lasted for three days. Hæmorrhage was not greater than hitherto.

On the following day the bladder was irrigated for half an hour with water at 115° F., and this treatment was followed for two weeks daily with great relief to the patient, sciatic and vesical pain and frequency of micturition disappearing under its use, and the quantity of residual urine gradually diminishing until at the end of the two weeks there were only two ounces. The amount of blood in the urine also became much less, the urine being occasionally almost clear. During this time the patient was given a nourishing diet and tonics, under which and with the diminution of the local symptoms his condition decidedly improved.

In the washing following the sounding bits which resembled detached portions of a new growth were

[1] Read before the Surgical Section of the Suffolk District Medical Society, October 6, 1884.

found, and for certainty as to their character they were taken to Dr. Gannett for examination, and from him the following report was obtained: —

"The bits removed by washing out the bladder varied in size from a pin's head to a small pea, all presenting a gelatinous appearance. Microscopically they showed masses made up of finger-shaped projections with rounded, club-like extremities. After maceration in Ranvier's alcohol and staining with hæmatoxylon it was found that the centre or stem of each projection was a blood-vessel surrounded by several layers of cells having large, clear nuclei, and a comparatively small amount of protoplasm. In my opinion the masses described are portions of a new growth from the mucous membrane known as papilloma."

The diagnosis being thus far established, it was decided to perform the exploratory operation of the bladder, as recommended and practiced by Sir Henry Thompson, and to remove the new growth if possible.

The patient's condition at this time was fairly good; he was well enough to move about the house; had a fair appetite; all the organs except the bladder, so far as could be discovered, were functionating properly; the pulse was strong. There was *no evidence* of the disease being anything other than papilloma of the bladder.

On January 20th, five weeks after first seeing the patient, the operation was performed, Dr. Porter being in consultation; Drs. A. T. Cabot, J. W. Elliot, and Howard Lombard being also present, and kindly assisting.

I may, perhaps, be pardoned for entering somewhat into detail as to the steps of the operation, for the reason that although its procedures are simple, it has been as yet but little practiced in this country. A grooved staff, No. 24 (French), was passed into the bladder, and held in the median line. An incision was then made in the perinæum from one inch below the scrotum to within half an inch of the anus; further incisions in the same line exposed the urethra, which was opened at the bulbo-membranous junction, and divided backward to the prostatic urethra, which with the neck of the bladder were then gently dilated, by pushing first the little and then the forefinger through them. Strong downward pressure above the pubes now brought the whole interior of the bladder within reach of the finger, which revealed the fact that a very large portion of the inner lining was occupied by a sessile papillomatous growth, the surface of which was soft and friable enough to be broken down in places by the finger, and was very vascular, as shown by the hæmorrhage which followed this procedure. The condition was confirmed by examinations of the other gentlemen present. A dull plated copper curette of this shape was then passed in above the finger, and the removal of the growth was undertaken by this means, alternating with an instrument which I devised to act as a strong, long finger nail, a description of which will be given further on.

The growth was so extensive that, at the end of an hour, although much had been removed, there was also a good deal left. Hæmorrhage was free and constant during the operation. The bladder was three times thoroughly irrigated for a few moments with hot water at a temperature of 125° F., which answered the double purpose of stopping the hæmorrhage and of washing out detached fragments of the tumor and blood clots, which rendered the continued steps of the operation more precise.

At the end of the hour the patient was so weak from the loss of blood that it was thought unadvisable to proceed further with the operation, and he was put to bed. He made an excellent recovery from the shock of the operation.

The urine came away involuntarily during the first twenty-four hours through the wound. A drainage tube was then inserted into the bladder for thirty-six hours, but at the end of this time it caused pain and vesical tenesmus, which ceased upon its removal. Hæmorrhage sufficient to tinge the urine persisted for three days after the operation, after which it disappeared not to return until within three weeks of the patient's death.

Twenty-four hours after the removal of the drainage tube distinct acts of micturition were reëstablished; their frequency was only once in from four to six hours. At the end of a week the patient, so far as his bladder was concerned, was perfectly comfortable. Previous to this he had occasionally with micturition severe pain, referred to the end of the penis. The neuralgic pain in the left sciatic region had quite disappeared.

For nine days the bladder was washed out with a warm solution of corrosive sublimate one to 15,000. At this time there was again some bladder irritation, which ceased after changing the corrosive sublimate wash for a borax solution or hot water; these gave a sense of great comfort to the patient.

The urine for about a week after the operation smelt badly, contained a good deal of pus, and became neutral. Soon, however, the bad smell disappeared, the amount of pus diminished, and the urine became again acid.

During the first four or five days succeeding the operation several bits of growth were passed with the urine through the wound. On the thirteenth day the patient was out of bed, had a good appetite, and was apparently doing well in every way.

Three days later, owing to the outer part of the wound having been allowed to close too rapidly, a slight infiltration of urine about its edges and into the scrotal tissues occurred, which, however, subsided in a few days on reopening the wound superficially. Coincident with the infiltration of urine was a rise of temperature, reaching 105.5° F. on the evening of the second day, falling again to normal on the fifth day.

A marked diminution in the quantity of the urine *then* occurred, and hyaline and granular casts appeared for the first time. Under the use of diluents and diuretics the quantity became normal in a few days, and the casts slowly disappeared.

With the rise of temperature just spoken of occurred also a flatulent diarrhœa. The stools were nearly colorless, contained undigested food and some fat particles. This condition returned once or twice during the patient's illness.

Peat or fossil meal bags saturated with a solution of corrosive sublimate, 1 to 2000, were found a very useful dressing for the wound, catching and retaining the urine and obviating the annoying sense of wetness which would otherwise have taken place.

The rises of temperature were treated by aconite and morphia and quinine.

The diet was as strong and nutritious as possible for the patient to bear. The attacks of diarrhœa and flatulency were treated by a mercurial cathartic and subnitrate of bismuth, and tinct. cardamon comp., and changes of diet which seemed appropriate.

On the 23d of February, a little more than a month after the operation, I was obliged to leave the patient, and for the remaining notes of the case, as well as for his kindness in assuming the care of the patient, I am indebted to Dr. A. T. Cabot.

At this time the diarrhœa returned, but was soon relieved by gray powder and liquor pancreaticus. A week later a fluctuating swelling about the size of half a lemon appeared over the left posterior superior spine of the ilium; severe and constant pain in the same region accompanied this manifestation. Soon after the pain extended to both legs, being most marked in the right.

A digital exploration of the rectum at this time gave an increased sense of resistance to the finger on the right side of the pelvis, but no distinct tumor could be made out.

A little later the fluctuating swelling already referred to was aspirated and about two and a half ounces of dark bloody fluid were withdrawn; it refilled in two days. About the same period a distinct tumor was detected just above Poupart's ligament, on the right side, extending about one inch above it, and occupying about the middle two thirds of the space between the symphysis pubis and the anterior superior spine of the ilium. This steadily increased in size until the patient's death, when it reached half way to the umbilicus. Constant pain, delirium, rapid emaciation, and a steadily diminishing quantity of urine now became the prominent symptoms, and with them the patient quickly failed, and died on May 5th, about two months and a half after the operation.

In closing the report of the case I wish to lay especial stress upon the fact that the performance of the operation, even in this hopeless condition, almost relieved the two prominent and distressing symptoms, — hæmorrhage and vesical pain. As will be seen from the specimen which Dr. Gannett will show presently, the intrinsic nature of the case did not allow the hope that more could be accomplished.

There are about forty recorded cases of primary new growths of the male bladder in which operations with a view to their removal have been undertaken with varying success. Of this number eighteen have occurred in the practice of Sir Henry Thompson, four in that of Mr. Whitehead, of Manchester, while the rest of the series, beginning with the case of Corvillard in 1639, contains those of Crosse, Desault, Le Cat, Civiale, Gersuny, Liston, Billroth, Kocher, Volkman, G. M. Humphrey, Berkeley Hill, Marcacci, Davies Colley, Morgan, Ransohoff.

Beside these in the male subject are others in the female, numbering more than sixty.

Moreover, there are many more for which no operation was undertaken, but which, as pathological specimens, have afforded observers the opportunity for the study of their nature.

Sir Henry Thompson has been able to collect no less than fifty examples of primary growths of the bladder from the various museums of London, added to which number the twenty cases which have been in his own hands makes a total of seventy. It must, of course, be borne in mind that this observer has had more widely extended opportunities for making such a collection than any one else.

Within one year in this town six cases of this class of disease have come to my notice, two of which have been in my own care, and four in that of other surgeons. I have thought it worth while to cite these figures to accentuate the fact that primary new growths of the bladder are not of very great rarity, and this impression would be confirmed, I am sure, if we had more exact knowledge in regard to many cases which have died without autopsy, and with a diagnosis of hæmaturia simply, amongst which no doubt a certain proportion would be found in which the source of hæmorrhage was a new growth in the bladder.

In view of these facts, and of the decided impetus which the surgical treatment of tumors of the bladder has received in late years, and the much greater success which it has met with under improved methods and more accurate knowledge, it may be useful to try to briefly summarize what experience has already taught us in this direction, and the prospect for the relief of a very suffering class of cases which it offers.

The variety of tumors which have been found in the bladder are: (1) Papilloma, (2) fibroma, (3) epithelioma, (4) carcinoma, (5) sarcoma, (6) myxoma, (7) myoma, (8) enchondroma.

The last is quoted on the authority of a case published in the *Gazette Médicale de Paris* in 1836, but its nature is open to doubt.

About fifty per cent. of all tumors of the bladder are papillomas, which term is meant to express the benign growths, pedunculated or sessile, having branching papillæ of greater or less length, which consist of a capillary loop of blood-vessel covered with epithelial layers, which, being very tender, allow hæmorrhage to occur readily.

Almost any tumor of the bladder may have a papillated surface, with which the true papillomas should not be confused. Moreover, a papilloma may become with time a cancerous growth.

The other varieties of new growth occur in relative frequency in about the order named.

The most common seat of tumors of the bladder is about the trigonum, but they may occur in any portion of the bladder.

DIAGNOSIS AND SYMPTOMS.

The two most prominent symptoms of new growths in the bladder are hæmorrhage and vesical pain, though they may both be absent through the entire course of the disease.

Hæmaturia varies in respect to constancy, time of appearance, and quantity of blood lost, with the nature of the tumor. If the growth be a papilloma it is generally the first, the most pronounced, and most unfailing symptom. In malignant growths it is more likely to be preceded by pain and frequency of micturition.

Hæmaturia is sometimes the only symptom throughout the course of the disease. The quantity of blood in the urine varies from enough to slightly tinge it to severe hæmorrhage, blanching the patient and filling the bladder with clots. These generally have the appearance of being formed from fresh hæmorrhage. They lack any characteristic shape, and are not firm and decolorized, as those formed in the pelvis of the kidney or ureters sometimes are. If there be no urethral lesion, and blood appears at the end of the act

of micturition, the inference that it is of bladder origin is justified.

The hæmaturia may be intermittent or constant, and its appearance in greater or less amount may be noticed in every urination for a period of years, as in the case of this evening. Exclusive of papillomas, the constancy depends probably upon the extent of superficial erosion present.

Microscopically blood corpuscles present the characters of fresh hæmorrhages, but it is an interesting fact that this is not invariable, as I have had occasion to observe in one case, in which the corpuscles showed in several examinations of the urine the features which belong to blood which has remained for a long time in the urinary tract, and this, too, in a case in which no condition obstructive to the outflow of urine from the bladder, such as stricture or hypertrophied prostate, was present.

There was also an entire absence of vesical symptoms, and these facts led to the inference that the hæmorrhage originated higher up in the urinary tract than the bladder. The autopsy, however, disclosed two tumors of the bladder, one near the orifice of each ureter, which were the source of the bleeding. The absence of blood, on the other hand, does not preclude the possibility of the presence of a new growth in the bladder, as is shown in several cases of Stein's, in which large tumors were present, and yet no hæmorrhages had occurred at any time during the malady.

Pain and vesical irritability are symptoms of the next importance to hæmaturia, which they may precede or follow, or be coexistent with. As already stated, pain may be absent. Its presence and severity are due in part to the situation of the growth (being most marked when it is in the vicinity of the vesical orifice), in part to the nature of the disease. It may be felt in the end of the penis, in the perinæum, at the vesical neck, at the sacro-iliac synchondrosis, or in the sciatic regions, and often occurs quite independent of any form of motion or exercise. It varies in intensity from a slight stinging along the course of the urethra to the severer forms accompanying vesical tenesmus. When in the sciatic region it is apt to be on the same side as the growth, but this is not invariable. It is generally most marked at the end of micturition, but this, too, is not always the case, as in the instance reported to-night, in which the pain was often most marked when the patient was at rest and independent of urination. In some of the cases reported actual pain has not been present, but difficulty of micturition has been mentioned, and described by the patient as straining.

Frequency of micturition is often increased, and attains its greatest height in those cases in which necrosis of the growth occurs, and is accompanied by a serious form of cystitis. It will be seen, therefore, that the two most important symptoms of these new growths, hæmorrhage and pain, may vary greatly in degree, from being, indeed, entirely absent during the course of the disease to occupying the most prominent place.

As a further aid to diagnosis, and this is of especial interest in the early history of such cases, the *urine* should be carefully examined. These examinations may give us only a suspicion or the most positive proof of the presence of a new growth that can be furnished. The normal characters of the urine in the early stages of the malady, and sometimes throughout its progress, may be unaffected, except that the color is altered by the presence of blood, and albumen appears in proportion to its quantity. Later the urine often becomes alkaline and fetid, contains large deposits of pus and triple phosphates, and finally may take on the characters of a fibrinuria, as described by Ultzmann.

The presence in the urine of large numbers of cells of varied shapes and having large nuclei has been noted by many observers in connection with new growths in the bladder. There is a general agreement that their existence has nothing necessarily characteristic in it, as the cells represent only such forms as are found in the mucous membrane of the bladder normally, and may be cast off and appear in the urine in conditions which favor maceration of its epithelial layers. Nevertheless, when present in the urine and coincident with hæmaturia, vesical pain, or difficulty of micturition, or when present without their appearance being explained by the existence of such a condition as just mentioned, they may be taken as strongly indicative of the existence of a new growth. On the other hand, their absence does not preclude the possibility of a bladder tumor.

The surest evidence which the urine can afford is the presence in it of bits of the growth. These vary from the smallest shreds of necrotic tissue to fleshy masses of considerable size and characteristic appearance. The smaller bits are difficult to detect in a urine which contains much blood, but the search is rendered easy by diluting the sediment largely with water, and pouring it out into several flat dishes.

Occasionally a bit of the surface of a papillomatous growth will be passed in the urine which is sufficiently characteristic in its tufted form to be recognized by the naked eye. More frequently, however, the detached portions come away in a necrotic condition so altered that they are difficult to recognize even under the microscope, but very small bits may show the elements of papillomatous growth. One should bear in mind, however, that the surface of the growths may be papillomatous while the base is cancerous, and that therefore microscopic examination alone is not conclusive evidence as to the nature of the tumor.

Leaving the urine and subjective symptoms of the patient, there are several aids which may be used to a furtherance of the diagnosis. These are capable of furnishing the most information if the patient be etherized.

Examination by rectum, with one or more fingers, will reveal the presence of a tumor which has to any great degree involved the bladder walls posteriorly, or has its seat in the prostate, by imparting to the finger a sense of increased resistance, weight, thickness, or induration, uniformly or unevenly distributed through the bladder wall. This search may be aided by bimanual palpation, the other hand exerting pressure above the pubes in a relaxed condition of the abdominal walls. A small, benign tumor, not involving the vesical walls, or a tumor situated on the anterior wall or fundus, even if of large size, in a fat patient, may quite escape detection by this means.

No better testimony could be brought forward to show that a tumor of the bladder may very readily fail to be noticed by an *exploration of the sound* or searcher than Sir Henry Thompson's assertion that such is frequently the case. In some instances, however, the diagnosis has been made by this means, and in the case of a hard, firm, circumscribed tumor it is quite conceivable that such should occur, but in most

cases the use of the searcher is chiefly valuable as a means of eliminating stone. It should be mentioned in this connection that a tumor of the bladder whose surface had become coated with urinary salts has been mistaken for stone, and it is quite possible to regard, on the other hand, an encysted stone as a tumor of the bladder, as in Dr. Otis's case. Before removing the sound it is well to replace the finger in the rectum, and examine as much of the bladder wall between it and the sound as can be reached.

If a catheter or searcher be introduced their eyes and contents should be carefully examined on withdrawal to see if a bit of the growth has not been caught and detached in the movements of the instrument.

All instrumental manipulations should be undertaken with great gentleness, as several instances of serious and one or two of fatal hæmorrhage have arisen from a lack of caution in this respect.

Irrigation of the bladder, especially immediately after the use of instruments, may furnish valuable information by washing out any detached fragments of growth. Such irrigations, if made with hot water, 125° F., will also be of service in stopping any hæmorrhage which may have originated during an examination.

With the steps just recounted all the ordinary means of diagnosis have been put in requisition, and there remains only one other method to be employed, namely, the *digital exploration of the bladder* as advocated by Sir Henry Thompson, which is justified when such symptoms as have been described render the probability of the presence of a new growth a strong one, or when, even in their absence, vesical disease is suspected, in which the obscurity of the symptoms is such that they cannot be explained by the supposition of the presence of the more ordinary pathological conditions of the bladder. For example, if a patient presents himself suffering from painful or frequent micturition, hæmaturia, and we can eliminate the presence of stone, of hypertrophied prostate, of ordinary cystitis as a reasonable source of the trouble, and are decided that the hæmorrhage is vesical, there is no doubt that digital exploration of the bladder should be undertaken after a reasonable time has elapsed without the disappearance or amelioration of the symptoms under treatment. And bearing in mind the exceptional cases in which neither blood nor pain are present, and where obscure vesical symptoms persist, digital exploration may become justifiable in the absence of further positive evidence of the presence of a new growth. The operation is not in such cases in itself dangerous, and one will not have the unpleasant surprise, in case of the patient's death, of finding at the autopsy a tumor in the bladder, perhaps of such a nature that it could have been easily and safely removed. Moreover, in a number of cases in which the operation has been undertaken under the suspicion that a new growth existed, and no growth was found, the patient has been greatly benefited and sometimes cured of his trouble, although the surgeon has been left in the dark as to the condition which he has relieved. Bearing this fact in mind, and linking it with the two others, namely, the slight risk attaching to the operation, and in default of it the possibility of the patient's dying unnecessarily of a disease which might have been cured or ameliorated, one may prophesy that digital exploration will be undertaken more frequently than hitherto.

The method has already been described in the report of the case. It is undertaken as a means for diagnosis, and as the first step in the operation for the removal of the growth if it exists, to the consideration of which we now come.

There are a certain number of growths which, from their nature, it is impossible to remove, either because of their size or of the great extent to which they involve the bladder walls or neighboring organs. But even in these the operation for digital exploration will at any rate often afford relief by securing drainage for the bladder, or, perhaps, enabling the operator to put a stop to hæmorrhage, by removing the surface of the growth, and often to allay the pain. Such relief to pain and hæmorrhage will not, it is true, follow the operation in all cases, but surely it is better to undertake it even if it is afforded in only a few than to allow the patient to go on through the inevitable series of painful events which must follow if he be let alone.

There are three conditions mentioned by Messrs. Whitehead and Pollard, and experienced by other surgeons as well, which may render digital exploration of the bladder from the perinæum and operation for the removal of the growth impossible. These are (1) "stoutness of the patient; (2) enlargement of the prostate and consequent elongation of the prostatic urethra; (3) an unusually narrow pelvic outlet."

Three methods of operation for removal of new growths from the male bladder have been practiced: —

(1.) Lateral cystotomy, as in the cases of G. M. Humphrey and Berkeley Hill.

(2.) Epicystotomy, as in those of Billroth and Volkman.

(3.) Median perineal cystotomy or urethrotomy, as advocated by Sir Henry Thompson.

A few growths have been removed by the lithotrite, but are only interesting as surgical events.

The lateral operation has the advantages that it gives more room to work in, and that it secures better drainage from the bladder afterwards. On the other hand there can be urged against it the facts that in its performance the base of the growth may be divided, giving rise to hæmorrhage difficult to control; that it is not so short a road to the bladder; that it is in itself a more serious undertaking. It must also be shown by its advocates that growths can be removed by this means which could not have been done by the median operation. In those patients who have hypertrophied prostates it might become more desirable.

Combined epicystotomy and median perineal urethrotomy was performed successfully by Billroth in his celebrated case. Volkman afterward failed to save his patient's life by a similar proceeding in a similar condition. Marcacci's case of epicystotomy died from the effects of the operation.

It has been urged by several surgeons on the ground of the greater ease and accuracy which it offers to them for the removal of the growth after the bladder has been opened. This is of course true, but does not thus far offset the disadvantages of the operation.

That the bladder has been freely incised without harm in ovariotomy does not furnish an argument in favor of epicystotomy, for the bladders which have been so injured have usually been healthy ones.

The high operation for stone, even with the improved methods and greater relative success which it has attained of late years, is still so open to the dan-

gers of urinary infiltration about the wound, peritonitis, and suprapubic urinary fistula, that it must be regarded as a much more serious undertaking than the urethral one, and the same holds true for new growths in the bladder.

There are, however, some growths which from their extent and size might be removable only from above the pubes, and in such cases if any operation is to be undertaken it should be epicystotomy. The additional step of combining an external urethrotomy with this operation to secure drainage and avert the danger of urinary infiltration is desirable.

Professor Guyon and his school have lately attacked Sir Henry Thompson's operation with the statement that "the suprapubic operation should invariably be employed in these cases, and the perineal operation never." Sir Henry's answer, I think, fully meets this, and sets the relative advantages and disadvantages of the two operations in a perfectly clear light; it is as follows: —

"There can, I suppose, be no hesitation in any one's mind that the high operation is a much more formidable and hazardous proceeding than the boutonnière. Why, then, should the former be practiced in any case until absolute certainty is attained not only that the tumor is present, but also that it is removable by operation? Now, it is only in a moderate proportion of suspected cases, say, perhaps, in two thirds of them, that the presence of the tumor can be regarded as strongly probable. In very few indeed can it be stated with certainty until the finger has entered the bladder. In no single case can the surgeon ascertain whether or no the tumor is separable from the bladder until the cavity has been opened and the interior examined. . . . All the data necessary for determining the question of operation can be attained by a slight urethral incision which involves no risk. What imprudence, then, can be greater than that of performing the high operation with all its admitted risks, while the operator does not know for certain that a tumor is present, and while he knows that if he does find one, the numerical chances are that the tumor, although thus completely approached and laid bare, cannot be entirely removed without inflicting fatal injury to the patient, since one half the cases are not completely removable.

"Further I declare, that while the boutonnière enables the surgeon to ascertain all the facts which it is necessary to obtain before operating, it also enables him to remove the tumor when it is polypoid in form, and therefore capable of being removed with a fair amount of ease and safety. If, however, he believes, and he is then in a position to determine the question, that he can attain a better result in any particular case by the high operation, there is nothing whatever to prevent his performing it."

For the reasons stated, therefore, the median perineal operation, having digital exploration for its first step, is of all procedures thus far proposed to be preferred. The method of its performance has already been detailed in the report of the case, and it only remains to say a word as to the instruments to be employed, and their manipulation, the cautions to be observed in operating, and the subsequent treatment. The instruments best suited to the performance of the operation for the removal of the growths are curettes, écraseurs, or snares, forceps, and the finger nail, or something which will serve its purpose better.

A broad based sessile papilloma or growth with a soft papillomatous surface, can often be broken down and scraped away by the finger nail. Wishing to have something rather more efficient, however, for this purpose, I had the following instrument made, which

answered very well. It is a skeleton finger cap, terminating in a moderately sharp-curved curette edge, which points downward. It is slipped over the index finger as far as the second joint, and held there by the spring action of its side arms, which embrace the finger in such a way as to allow, however, free movements to both the joints and consequently to the pulp of the finger, which can feel the surface of the bladder, localize the growth, recognize its extent, and as the operation proceeds how much has been taken away, and then employ the sharp edge of the instrument, so guided by the touch, for the removal of the growth. It has the advantage that the finger does not need to be withdrawn and reinserted in alternation with an instrument; the finger and instrument work as one in the bladder. A uterine curette working beside the index finger of the other hand is also a serviceable instrument.

Pedunculated growths may be snared, cut through with an écraseur, or they may be seized and bitten off with forceps, the best form of which has been devised by Sir Henry Thompson.

The following precautions should be observed in operating: —

The suprapubic pressure which is necessary to bring the interior of the bladder and the growth within reach of the finger should not be continued during the actual employment of the instruments, else it may easily happen that the bladder wall, being inverted by the pressure, may be caught between the blades of the forceps and nipped off, or perforation may be readily caused if a curette is being used. Again, one should be careful to avoid any attempt to bite, twist, or curette away the growth to the extent of making a flush and smooth surface. This is not necessary for the success of the operation, as the wound in cicatrizing will accomplish this for itself, and one incurs the danger of perforating the bladder.

If forceps be used, their movements should be twisting, chewing, crushing, and traction should be avoided.

Frequent digital examinations should be made to determine the progress of the work and recall the exact locality of the growth.

Decided assistance may be gained by washing out the bladder with hot water from time to time. Clots and fragments which obscure the work may thus be removed, and hæmorrhage decidedly checked.

Messrs. Whitehead and Pollard recommend the injection into the bladder of undiluted liquor ferri perchlor. to check hæmorrhage, if it is required in the course of the operation, and state that its use for this purpose is followed by no untoward result.

The treatment subsequent to the operation will of course vary with the circumstances of each case. A short, soft rubber drainage tube may be inserted into the bladder for from one to four days, taking care to change it each day to avoid clogging and uncleanliness. Through this the bladder may be washed out with any one of a number of antiseptic solutions, such as corrosive sublimate in the strength of one to 10,000 to one to 15,000, or stronger if the bladder will tolerate its presence, or permanganate of potash (potas. perm. .04 gramme, aquæ 200 grammes), saturated solution of boracic acid,

or simply hot water at a temperature of 110° F. to 125° F. The washings should be repeated daily, and generally will be found to afford relief to the patient.

The drainage tube will not be well borne by some patients, and when this is shown it should be removed at once. The fossil meal or peat bags will be found to make a serviceable dressing for the outer wound.

The autopsy in the present case showed the presence in the bladder of a primary villous cancer occupying about two thirds of the inner surface of the organ, and extending deeply into the muscular coat. On the right side the growth had extended laterally, involving the bones of the right os innominatum, causing absorption and disappearance of the body and ramus of the pubes, ramus of the ischium, the whole of the acetabulum, with that portion of ilium forming and adjacent to the acetabulum, thus making an opening in the pelvis rather larger than the palm of the hand. Through this opening projected the femur, the head and most of the neck lying in the cavity of the pelvis. The bones forming the edges of the opening described were found, microscopically, to be the seat of a cancerous growth. The head of the femur at the point of attachment of the ligamentum teres was eroded, forming a cavity large enough to admit the tip of the little finger. On section of the bone and microscopic examination it was found that the head and neck were infiltrated with a cancerous growth like that already mentioned.

In addition to the direct extension of the new growth from the bladder to the bones of the pelvis and the femur there were also found cancerous nodules in the lungs, the size of walnuts, evidently resulting from embolism.

The tumor, from its seat in the bladder, had compressed somewhat the opening of the right ureter, leading to a moderate degree of dilatation of the right ureter and to a partial hydronephrosis.

SUBCUTANEOUS INJECTIONS IN INTESTINAL PAIN; THEIR SAFETY AS COMPARED WITH OPIATES BY THE MOUTH.

BY E. M. BUCKINGHAM, M. D.

WHEN called to a patient suffering pain, one of the obvious ways of giving relief is by the use of opium in one of its forms. If the pain has its seat in the intestines, other methods of treatment may be considered, as either an emetic or a cathartic to remove irritating ingesta, but there are cases even when irritating ingesta are known to be present in which a cathartic seems to act more surely and more pleasantly after the removal of spasmodic contractions accompanied by pain, and there are also cases in which humanity demands the relief of pain without waiting for the slow action of cathartics, and others again in which the diagnosis being a matter of doubt a cathartic may be dangerous, while the irritating ingesta, if present, have apparently passed the point when they can be reached by emetics. In such cases the use of opium is undoubtedly the practice of the profession. It may be given by the mouth or the anus, or by subcutaneous injections. It is well recognized that the subcutaneous injection is rapid in its effect, and this, of course, is an argument for its use, but it has occurred to me that there is another advantage as well, that of safety; and that this is the more worth dwelling on that there are practitioners who dread the subcutaneous syringe on the ground of danger. That it has its dangers is a well-recognized fact; that they may be avoided by care is commonly agreed upon; that there is ever any danger in giving opiates by the mouth that does not belong to the hypodermic injection, and that such cases may in a measure be recognized, is something that has not been dwelt upon, so far as I am aware.

It is, however, well established that in certain conditions the intestinal canal does not digest and absorb food, sometimes does not absorb because it does not digest, and it is equally well known that fatigue or mental excitement may be the cause of this non-absorption; that is, a cause which acts through the nervous system independently of the particular contents of the intestine. It seems, too, that this nervous cause does not always act merely by stopping digestion, but that it also prevents the absorption of materials that are in themselves ready to be absorbed. At least I can explain in no other way the cases occasionally reported on good authority in which enormous doses of laudanum have been taken either for suicide or by accident, and which have been retained long enough to be fatal, but have produced in some cases no symptoms, in others none of any severity. Such cases are to be found scattered through medical literature, and need not be repeated here.

If it be granted, as it must be, that fatigue, cold, or mental excitement are at times causes acting through the nerves and preventing absorption, or at least preventing digestion, it may be more readily accepted that pain may have a similar effect. Whether it actually does so or not is a matter to be decided by clinical experience, and probably in no other way. I think that I have seen some evidence that it does, but not enough to make the matter certain; and it is in hopes of comparing notes with others, or at least of drawing attention to the subject, that this paper is presented.

CASE I. A gentleman has had several attacks of pain, which, as will be seen later, it is necessary for my purpose should be shown not to be due to calculi. This gentleman, who is of middle age, has for years managed a large business alone, getting little exercise, and keeping a luxurious table. He has a habitually coated tongue. There have been extra fatigue and anxiety, with lunch omitted and dinner postponed; or some recently eaten article of food has been tasted for hours before the onset of pain; or on one occasion the exciting cause seemed to be an indiscretion in diet while in bed with a carbuncle, followed by sleeping exposed to a strong current of air, by which his wife also took cold. One or the other of these supposed causes has preceded each attack. Furthermore there has never been pain referred to the penis, the thigh, or the testicle, which last has not been retracted. The liver has never been large nor tender, and with one slight exception there has been no jaundice. The pain has been general over the abdomen rather than local, and when once controlled by opium, at whatever stage of the attack, has not returned except once, when it ended with a diarrhœa.

This is not the history of calculus, and the sudden cessation of pain to be reported has evidently a different explanation.

The history of the particular attack to which I refer is as follows: He had headache for a few days, was very and anxiously busy, and was all day out of town in the cold, and with nothing to eat after breakfast

until night. Pain began in the following afternoon, somewhat suddenly, and he was given a subcutaneous injection by a physician down town, the amount unknown. When I saw him at his house the abdomen was tympanitic, and he was regurgitating gas. Was still in great pain, though a little easier from the injection. Because of the partial relief, together with the unknown quantity of opium taken, he was given small, frequently repeated doses of morphia by the mouth. When I next saw him, four hours later, he had taken by the mouth five sixths of a grain, the pain was at least no easier, and the pupils were not contracted. Soon after I entered the room he vomited for the first time, bringing up green liquid very freely, but nothing else. After waiting a short time to see if vomiting would give relief, I did what I should have hardly dared had he not vomited, gave a sixth of a grain subcutaneously, and with the effect of giving complete ease, relief beginning in something less than a half hour. He then dozed off and on for three hours, and then slept for three, but there was no return of pain, and in the morning, some twelve hours after this last injection, neither the pupils nor the skin showed the effects of opium.

Now if it be assumed that his stomach was in ordinary working order it follows that of the five sixths of a grain given by the mouth the most must have been absorbed. In addition to this a sixth of a grain was given by me and something given down town. It will be safe to say that the man took over a grain of morphia during a few hours, and it must be assumed either that he deceived me by complaining after the pain was partly relieved by the absorption of this large dose, which supposition is contradicted both by the character of the man and the absence of any effect on the pupils, or that no effect was had from five sixths of a grain, while the addition of a single sixth gave complete relief, a result not in accordance with common experience, and in either case we are left to account for a grain of morphia being taken in a short time of the late afternoon and evening, and leaving no effects perceptible early on the following morning.

On the other hand, if the stomach was not absorbing a dangerously large dose was collected there, and remained inert until it was, fortunately, vomited, after which the pain was relieved by a comparatively small dose placed where it could be of service, and there were no manifestations of a large dose, because that had been rejected after lying useless for some time.

To assume certainly that the non-absorption was due to pain would be going too far, but it was not due to the presence of any large amount of mucus, so far as one can judge by the vomitus, while the next dejections contained nothing but some old fæces. That there was a connection between this non-absorption and the presence of intestinal pain seems probable, partly in the absence of any other explanation, partly in view of the fact that abdominal pain sometimes causes vomiting, as witness the vomiting that accompanies tenesmus in dysentery, even in cases where the stomach contains no food, and there is no vomiting, except at the times of dejections, and partly in view of the next case to be reported.

CASE II. A lady, ill with dysentery, was given morphia many times both by mouth, by rectum, and by the skin without showing any idiosyncrasy with regard to its use. For several days during a part of the illness nearly every dejection was accompanied by vomiting. On one day she was given a sixth of a grain of morphia for the relief of distressing and persistent tenesmus, and this was repeated twice in eighth grain doses, making nearly a half grain in all, but with no apparent effect. I saw her an hour and a half after the last dose, and, remembering the previous case, injected a twelfth grain subcutaneously. Very shortly the pain became easy, the pupils were much contracted, and she sunk into an unusually sound and prolonged sleep. The long and sound sleep might be accounted for by the relief of pain in a worn-out woman, but not the contracted pupil. She was certainly affected powerfully by the opiate, of which by far the greater part had been taken from an hour and a half to several hours before showing its effects. Furthermore, nearly a half grain had been taken without effect; a twelfth grain injected was followed at least by relief, and this relief was not merely caused by the repeated addition of dose after dose, as is seen from the long interval between the two last doses, and the overpowering effect when the drug did act. I can find no explanation of this case unless the large dose, made up of small ones, lay inert together until the pain became lessened, and then the whole morphia, that given by the skin and that by the mouth, entered the circulation together with effects to be expected from that dose.

That the partial relief to pain given by the small injection was the cause of the stomach beginning again to absorb is not certain, but the coincidence is at least suggestive.

Unquestionably the stomach will almost always absorb an opiate. It is probable there are times when it will not, and one indication of this condition may be intestinal pain. If, as these two cases suggest, though they do not prove, the presence of intestinal pain has sometimes an effect in preventing absorption, it follows that in such cases opium by the mouth is uncertain, and if pushed may become dangerous; if given at all may make the after use of the syringe dangerous.

My own practice has been for some time to inject morphia in these cases, and to stay with the patient until he becomes easier. Only when relief has begun, to leave an opiate to be used provisionally.

If discussion shall remove my fears in this matter, and lead me to a less cumbersome practice, the trouble of writing will be amply repaid.

A CASE OF CALCULUS IN THE FEMALE BLADDER. REMOVAL BY BIGELOW'S OPERATION.

BY J. G. PINKHAM, M. D.

THE patient was a small, feeble-looking woman, about thirty years of age. In February, 1881, six months after the birth of her first and only child, she began to experience a smarting sensation during and after micturition. Previous to this there had been no vesical disorder, and there was no history of renal colic. Not long after the smarting began she noticed a gritty substance in the urine. A good deal of this in the form of fine sand, with some larger pieces, escaped in the course of a few months, the symptoms meantime increasing in severity, and the urine becoming offensive, thick, and bloody. After a time, the exact length of which could not be stated, the gravel

ceased to be passed. When the case came into my hands many of the symptoms of vesical calculus, such as frequent and painful micturition, sudden stoppage of the stream of water, a sense of weight in the bladder, pain from sudden motions of the body, etc., were present, and the patient's general health was much impaired. On passing a steel sound into the bladder the stone was at once discovered, and shown to be of considerable size.

The operation for its removal was performed at the patient's home on the 19th of December, 1883, Drs. Lovejoy, Colman, and Sheldon assisting. The instruments employed were a series of elastic bougies, a pair of long, slender forceps, a Thompson's lithotrite, a Davidson's syringe, and a piece of rubber tubing about two feet long, and one half inch in diameter.

The urethra was first dilated rapidly up to No. 30 of the French scale. It then easily admitted the lithotrite. There was little difficulty in getting hold of the stone, which, as grasped by the lithotrite, measured about four and a half centimetres in diameter. It was soft and readily crushed, but the instrument frequently became clogged, necessitating withdrawal for the purpose of clearing the jaws. Several pieces were removed by the forceps. The remainder was washed out by means of the rubber tubing and Davidson's syringe, the process being to pass in the tube, fill the bladder, and then, depressing the outer end of the tube as far as possible below the level of the table upon which the patient was lying, to allow the water to flow out. In this way it was found quite easy to remove the detritus from the bladder. The patient did not bear the anæsthetic well, and at one time, when we were fairly under way with the operation, she suddenly ceased to breathe, and turned livid. Active efforts were required for some minutes (as it seemed) to induce respiration, and when this did begin again it was attended with an abundant discharge of white froth from the mouth and nostrils. Again after this, an attempt being made to push the anæsthetic to the extent of relaxing the lower limbs, alarming symptoms, similar to those descrioed, though less in degree, supervened. Hence it was found necessary to endure a certain amount of moving about on the part of the patient, and to work more slowly than we might have done had we been able safely to induce complete anæsthesia.

The time occupied in the operation was about two hours. Very little blood was lost, and little injury done to either bladder or urethra.

One hour and forty-five minutes after the operation the patient had a temperature of 99° F., and a pulse of 124 per minute. Her mind was clear, and she complained of pain in the bladder and head. She was given a rectal suppository containing one third grain each of morph. sulph. and ext. bell. Four hours later her temperature was 100.8° F., and pulse 124. She had passed water twice with some gravel. Was bright and cheerful, and had no pain.

December 20th, morning. Passed a comfortable night. Temperature 98.4° F. Pulse 108. Has had but little discomfort when passing water, and no incontinence. From this time on the patient's recovery was uninterrupted. In a week she was about the house. Six weeks later she was found to be free from vesical trouble, and to have gained much in flesh and strength.

The portion saved of the calculus weighed a little more than half an ounce. Its principal constituents were uric acid and the urates of the fixed alkalies.

The operation of litholapaxy, or lithotrity at one sitting, introduced by Dr. Bigelow, seems to be especially appropriate for the removal of calculi from the female bladder, inasmuch as the urethra is short and easily dilated, and no complicated and expensive evacuating apparatus is required, as shown in this case. Professor Heath used a vulcanite-urethral speculum and a Higginson's syringe to wash out the detritus.[1] He, however, had dilated the urethra to the extent of producing rupture, and had introduced his forefinger. With the method adopted in my case there is no need for any except a very moderate dilatation. Heath claims that no harm resulted from extreme dilatation in his cases. I have myself dilated the urethra so as to introduce the finger for the purpose of removing small calculi and calculous encrustations of the vesical mucosa. In these cases there was a moderate amount of rupture of the meatus superiorly, but the patients recovered promptly. Yet instances are not unknown in which this procedure has been followed by prolonged incontinence. Sometimes, indeed, the vesical sphincter never regains its control over the contents of the bladder. Such a result would be an evil second only to the retention of the calculus. Hence the inquiry is pertinent why the patient should ever be subjected to such a risk. The caustic application recommended by Mr. Heath can be applied through the urethral speculum without extreme dilatation.

Vaginal cystotomy will probably always have to be resorted to in certain cases, such as those of foreign bodies which cannot be removed *per urethram*, encysted calculi, etc., but for all ordinary cases of stone in the female bladder it is safe to say that litholapaxy will be the operation of the future.

Hospital Practice and Clinical Memoranda.

PREGNANCY AND OVARIAN CYST. OVARIAN TUMOR IN A WOMAN OF NINETY YEARS.

BY W. P. GIDDINGS, GARDINER, ME.

THE following cases I thought might be of sufficient interest to the readers of your valuable journal to warrant their being reported: —

I. Mrs. S., aged twenty-four, American, first noticed an enlargement of the abdomen in 1879. She consulted Dr. S. Whitmore, now deceased, who diagnosticated pregnancy complicated with an ovarian growth. A consultation was held with our veteran surgeon, Dr. H. H. Hill, of Augusta, who advised tapping of the cyst for temporary relief. At full term she was delivered of a strong, healthy boy, now living, three years of age. The mother made a good recovery from confinement, and the tumor refilled in some four months. Tapping was repeated at various intervals five times, the last two being done by the writer, removing respectively thirty-five and thirty-three pounds. On the 26th of June, 1882, I operated upon her, removing a multilocular ovarian tumor, weighing with its contents fifty pounds. Recovery perfect and uninterrupted, save a little cystitis lasting a few days. On June 16th of the present year I attended her at full term with a fine healthy

[1] See London Lancet of December 23, 1882.

boy weighing ten pounds; labor normal and easy. In quite an experience with ovarian disease this is the second I have seen in which pregnancy supervened. The first, in Boston, passed from under my observation, and its subsequent history I do not know.

II. Mrs. W., aged ninety years eight months, had been noticing an abdominal enlargement for nearly a year, which, increasing to an uncomfortable degree, she sought counsel of a physician, who diagnosticated ascites. I was called April 4th in consultation to tap if it was thought advisable.

The most distressing feature of the case was a profuse and constant salivation, precluding nourishment and sleep. A careful examination revealed an ovarian tumor, and tapping was advised, which I did on April 10th. The old lady, unusually bright and intelligent, related during the operation many interesting medical experiences in her life, and remarked upon the advancement in medical and surgical science since her early life. The fluid removed weighed sixteen pounds. On August 9th I tapped her the second time, removing fifteen pounds; and the day following, being her ninety-first anniversary, she received and entertained several callers. At this writing she is in excellent health, reads with as much interest the daily paper as any person in our city, and discusses the prospects of our presidential election with the interest of a politician.

This is the rarest case of an ovarian growth that has ever come to my knowledge, though I assisted my friend Dr. Crooke, of Augusta, Me., in removing one from a lady seventy-three years of age, which weighed fifty-five pounds, and her recovery was as rapid and uninterrupted as any I have ever seen.

Reports of Societies.

MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION, ST. LOUIS, OCTOBER 14, 15, 16, 17.

THE American Public Health Association opened its twelfth annual meeting in St. Louis on Tuesday morning October 14th, and after the usual preliminary work proceeded to the discussion of the various topics which had been previously arranged.

A large number of papers were read, embracing the following subjects: The Hygiene of Occupations; The Hygiene of Habitations; The Hygiene of Schools and School-buildings; Heating and Ventilation; Food and its Adulterations; The Disposal of the Dead; Cattle Transportation and Diseases; Water Pollution, and Analysis; Sewerage and the Disposal of Sewage; The Germ Theory of Infectious Diseases; The Health of St. Louis.

In addition to these special meetings were held of the Conference of State Boards of Health, at which the subject of Cholera and the work of State Boards were the chief topics of discussion.

Of the sixty or more papers presented at the meetings of the Association, either in full or by title, a few only need to be mentioned as presenting points of marked professional interest.

On Thursday evening DR. GEORGE M. STERNBERG, U. S. A., delivered a popular lecture on

DISEASE GERMS,

illustrated by photo-micrographic views by means of a stereopticon. Dr. Sternberg presented the historical view of the subject, embracing the researches of Koch and other observers, and also detailed his own experience with reference to the search for yellow-fever germs at Havana. He had thus far been unsuccessful in finding anything characteristic, and also expressed his disbelief in the assertions of others who claimed to have found such germs, mentioning especially the bacillus of Dr. Domenigos Freire.

Views of the bacilli of tuberculosis, splenic fever, and other diseases were shown upon the screen.

His paper was followed by another by DR. L. BREMER, of St. Louis, on the Bearing of the Discovery of the Bacillus Tuberculosis on Public Health, in which the author expressed very decidedly his belief in the infectious nature of the disease.

The paper by SURGEON CHARLES SMART, U. S. A., on the

PRESENT AND FUTURE OF WATER ANALYSIS,

was one of the best of the session. He expressed very decidedly the impossibility of chemical analysis of itself alone, and without the knowledge of other associated facts or factors, to determine the question of purity or impurity of any given water with reference to its power of communicating infectious disease. Pollution and danger may be affirmed, but purity and freedom from danger cannot be affirmed. His statements were in harmony with the results of experiments recently made by Dr. R. Cory, for the Local Government Board of England, and confirmed by analysis made for him by Dr. Duprè.

Two papers on

THE HYGIENE OF OCCUPATIONS

deserve special notice. One by PROF. GEO. H. ROHÉ, of Baltimore, on the general subject, in which the Reports of the Massachusetts Bureau of Labor were largely employed for the purpose of illustration.

Another paper, presented by DR. WALTER WYMAN, United States Marine Hospital Service, detailed with much minuteness the Hardships of the Chesapeake Oystermen. He showed that this class of men were subject to great suffering and danger in consequence of brutal treatment, exposure to the inclemency of the oystering season, and serious injuries received by the cranks of dredging-machines.

ADULTERATION OF FOOD AND DRUGS.

Several papers were presented on food adulteration, both general and special. One paper in particular showed a lamentable want of knowledge of actual facts as to existing conditions, and repeated some of the older traditions and long-exploded statements of earlier writers as though they were verities of the present day.

DR. B. F. DAVENPORT detailed his experience as Analyist of the Massachusetts Board in the examination of drugs, and also as Inspector of Milk for the City of Boston; and explained the operation of the laws of Massachusetts with reference to the subject of food and drug adulteration. He also advocated the organization of a society of public analysts on a plan similar to that adopted in England.

DR. J. C. MORRIS, of Philadelphia, presented a paper on the Milk Supply of Large Cities, wherein he showed the immense importance of this article of food, and

proposed its delivery to customers in glass jars as a practical solution of the adulteration question.

SCHOOL HYGIENE.

Of the papers on School Hygiene the following were notable for their able presentation of the subject: —

DR. FELIX FORMENTO, of New Orleans, on the general subject.

DR. E. S. ELDER, of Indianapolis, on the Sanitary Survey of the School-houses of Indiana.

DR. S. O. RICHEY, of Washington, D. C., on the Hygiene of the Eyesight of School Children.

PROF. E. M. HARTWELL, of Johns Hopkins University, on Physical Training in American Colleges and Schools.

CREMATION

received its share of attention both as a mode of disposal of the dead, and for all refuse material, garbage, and solid material of sewage. Two papers were presented by ardent advocates of "Sanitation by Fire."

WATER POLLUTION.

In the matter of water pollution DR. H. B. BAKER the veteran secretary of the State Board of Michigan, presented the subject of the relation of the depth of water in wells to the prevalence of typhoid fever, illustrating his subject by diagrams showing the depth of water for several years, and the prevalence of typhoid fever during those years.

LOMB PRIZES FOR ESSAYS.

On the second day of the meeting it was announced that Mr. Lomb, of Rochester, N. Y., had offered to the Association the sum of $2000 to be distributed in the form of prizes for essays on the following subjects: Healthy Homes and Foods for the Working Classes; Sanitary Conditions and Necessities of School-houses and School Life; Disinfectants and Individual Prophylaxis against Infectious Diseases; Appliances and Means for Saving Life, and for Protection against Injurious Influences of Occupations on Health.

It is understood that these papers are to be submitted, before April 1, 1885, to a committee appointed for the purpose.

THE SANITARY CONDITION OF ST. LOUIS.

Several papers had been announced on topics relating to the sanitary condition of St. Louis, but, having been reserved for the last day's session, at which time the attendance was considerably diminished, a portion were omitted.

It is sufficient to say that the sanitary condition of the city has been decidedly improved since the great cholera epidemic of 1866, in which year there were 3527 deaths from cholera out of a population of 204,000. The death-rate for 1883 was 21.35 per 1000. Population 383,006.

Carefully prepared maps showing these facts, together with the portions of the city furnished with water-supply and sewerage, were distributed to the members of the Association.

INCIDENTAL MATTERS.

A prominent and new feature coincident with the meetings of the Association was the Conference of State Boards of Health, of which several sessions were held during the week, an organization having been effected for the purpose. The principal subject of discussion was the cholera, and the question of the efficiency of quarantine was the mooted point.

In comparing the meeting of the Association with those of previous years it may be said that the undue length of some of the papers presented upon general subjects prevented the discussion of papers of greater and special value.

The prevalence of unexceptionable weather through the entire session enabled the members of the Association to accept the cordial invitations of various organizations to visit the public institutions, parks, clubs, libraries, and other places of interest.

Public addresses of welcome were given by the Governor of Missouri, Mayor of St. Louis, President of the State Board of Health, and a brilliant illumination of all the public streets and buildings took place upon Wednesday evening.

ELECTION OF OFFICERS.

The officers chosen for the following year were as follows: —

President, Dr. James E. Reeves, of West Virginia.

First Vice-President, Hon. Erastus Brooks, of New York.

Second Vice-President, Dr. Henry B. Baker, of Michigan.

Treasurer, Dr. J. B. Lindsley, of Tennessee.

Secretary, Dr. Irving A. Watson, of New Hampshire.

Executive Committee, Dr. H. P. Walcott, of Massachusetts; Dr. Charles Smart, United States Army; Dr. George B. Thornton, of Tennessee; Dr. J. W. Hand, of Minnesota; Dr. Gustavus Devron, of Louisiana; Dr. H. B. Horlbeck, of South Carolina.

Among the names of new members elected were those of Dr. Charles Harrington, of Boston, and Mr. John Wells, of Winthrop, Mass.

It was decided to hold the next meeting at Washington, D. C., in December, 1885.

SUFFOLK DISTRICT MEDICAL SOCIETY.

SURGICAL SECTION.

S. J. MIXTER, M. D., SECRETARY.

OCTOBER 6, 1884. DR. F. S. WATSON read a paper on

TUMORS OF THE BLADDER IN THE MALE, ILLUSTRATED BY A CASE.[1]

DR. GANNETT, before giving the results of the autopsy, made some remarks in regard to tumors of the bladder, saying that they developed from the mucous membrane. Over a circumscribed area the mucous membrane might grow upwards, projecting into the cavity of the bladder, or downwards into the muscular coat. In the former case one had to do with a papilloma, in the latter with a cancer. Further, there might be a combination of both.

As regards the papilloma, the arborescent structure is

[1] See page 409 of this number of the JOURNAL.

its distinguishing feature, it presenting a villous appearance. Each villus is made up of a thin-walled, branching capillary, covered by a many-layered, flat epithelium similar to that lining the bladder. So delicate are these that a slight violence is sufficient to lacerate them, and so permit of a hæmorrhage.

These growths may be either sessile or attached by a larger or smaller pedicle, the pedicle often being very small in proportion to the size of the tumor.

Alcoholic preparations illustrating these varieties were shown.

As regards diagnosis of new growths by examination of the urine, this often affords the only means of coming to a positive conclusion in cases where a suspicion of tumor has arisen, either from the existence of intermittent hæmaturia, or vesical tenesmus, or both.

In the urine from such cases are found red blood corpuscles, as a rule in a fresh condition, rarely degenerated; usually polymorphous epithelial cells, sometimes singly, sometimes in clumps. Such cells, when abundant, point very strongly to a new growth, though they are not absolutely conclusive. The diagnosis is rendered certain only by finding portions of the tumor which have become detached and passed with the urine. It is often difficult to find these, owing to the fact that so long as the villi remain undegenerated they are not separated from the wall by the contractions of the bladder; whereas if they become degenerated and cast off they are usually in the form of a granular mass, and nothing characteristic can be made out.

Since, however, the symptoms often lead to a suspicion of stone, sounding is frequently practiced. Bits may, in this way, be torn off and removed in the eye of the cathether. Such bits show a typical structure, and lead one to a positive diagnosis.

Where cystitis is associated with the tumor the villi often become incrusted with crystals of phosphate of lime and triple phosphates. Such masses may be broken off, and cause intense pain in their passage through the urethra with the urine.

It is a noticeable fact in connection with these tumors of the bladder that, whereas in other parts of the body papillomata are benignant and cancers malignant, here it makes, as a rule, very little difference to the individual, *unless he is operated on*, whether the tumor be a papilloma or a cancer, in that hæmorrhage is the important factor in either, and will eventually lead to a fatal termination.

DR. C. B. PORTER reported from memory a case in which he had performed the operation. The patient was a man past middle life. The prominent symptoms were vesical pain, requiring large doses of morphine for its relief, and hæmorrhage. The diagnosis of a papilloma was made chiefly from the microscopic examination of the urine, in which were found bits of necrosed arborescent shaped growth. These pieces were at times of sufficient size to completely block the urethra. This was the first operation of the kind done in this vicinity. It was made in the median line, and it was exceedingly difficult to reach the bladder on account of the great depth of the perinæum. It was considered at that time that the entire growth was not entirely removed. The relief, however, to pain and hæmorrhage was complete until the man left the hospital. The only subsequent history known was the newspaper announcement of his death three or four months afterwards.

He thought that the operation of cystotomy had a large future both for the removal of new growths and for relief in cystitis. Thompson's median operation is the best; that over the pubes should only be used in rare cases, and then always supplemented by opening through the perinæum to insure perfect drainage.

DR. E. S. WOOD said in relation to the microscopic examination that in his experience the finding of well-defined arborescent tufts was rare. The presence of large patches of polymorphous cells should always be looked upon as suspicious; as, although they may theoretically arise from desquamated bladder epithelium, this practically only occurs in urine that has been drawn after death, and which has had time to macerate the mucous membrane.

DR. A. T. CABOT said that towards the end of the patient's life, in the case reported, hæmorrhage returned and was quite constant. As to the different operations, he thought that they must be still considered as *sub judice*, and that greater experience will enable more precise rules to be formulated. Guyon and his followers believe in the suprapubic operation, which is facilitated by the introduction of a rubber bag into the rectum, by filling which with water the bladder is forced up, and thus additional space is gained over the symphysis. Where the operation is for relief only he considers the perineal one preferable.

He recalled the case of a man sixty years old who had had symptoms of intermittent hæmaturia for a year and a half. No great pain, but great cacchexia. He was sounded to eliminate stone, and two fleshy looking masses came away upon washing, which were apparently blood clots coated with small cells. No operation was attempted.

DR. ABNER POST spoke of a case of malignant tumor of the bladder, seen by him during the past summer. He called attention to the value of negative evidence furnished by rectal examination. When the history of a case pointed to the presence of a tumor in the bladder, the absence of any thickening of the walls as felt by the finger in the rectum, would be strong presumptive evidence that the supposed tumor was a benign papilloma, and would aid in the elimination of malignant disease. He also suggested the use of Bigelow's evacuator as a help in diagnosis, as used by Sir Henry Thompson in his last few cases.

DR. WATSON said, in answer to an inquiry, that hot water injections for the relief of vesical tenesmus can be kept up from ten minutes to half an hour, commencing with warm water and gradually increasing the heat. He had employed water as hot as 125° F. with nothing but beneficial effect.

NEW YORK COUNTY MEDICAL ASSOCIATION.

AT a meeting of the Association, held October 20th, DR. AUSTIN FLINT, SR., read a paper on

THE PARASITIC DOCTRINE OF EPIDEMIC CHOLERA,

in which he took much the same favorable view of Koch's observations on cholera that he did of his investigations into the specific origin of tuberculosis in the paper which he read before the Association a few months ago. He said that in order to accept the fact that cholera was a parasitic disease it was not neces-

sary to have personally verified by microscopic studies the existence and agency of its special micro-organism. If the claims of such an organism were substantiated by the confirmatory observations of a sufficient number of competent judges it was all that could be asked. Fortunately, there had been no opportunity for studying the cholera microbe in this country, but when he was in London during the past summer he had had an opportunity of seeing in the biological department of the Health Exhibition a specimen of the so-called comma bacillus which had been prepared by Koch himself.

At the present day it was regarded as logically certain that all of the infectious diseases were due to a distinct and specific causative agent of some kind, and that it was most probable that this causative agent was a living organism. A number of years ago the name of *zymotic* had been given to such diseases by Farr (the word zymosis signifying fermentation), because he believed that they were due to a morbific agent of the nature of a ferment. It had since been shown by Pasteur that this ferment was a micro-organism, and a strong confirmation of what had long been a favorite hypothesis was thus afforded. In this connection Dr. Flint alluded to the remarkable paper of the distinguished American physician, Dr. J. K. Mitchell, on the Cryptogamic Origin of Disease, which had appeared nearly fifty years ago. There was now no room for question that in several infectious diseases the existence of a special micro-organism had been established, and if this fact could be positively demonstrated in a single one of these it seemed fair to reason by analogy that all such diseases were due to similar specific agents.

In regard to epidemic cholera much had been added to our knowledge within the past few months. In 1883 Koch had been sent to Egypt by the German government to make a study of the disease. He had afterwards gone to Calcutta for the same purpose, and subsequently pursued his investigations at Toulon during the recent epidemic at that place. The results of his observations he had embodied in a series of reports to the German government, and at the Cholera Conference held in Berlin on the 26th of July last, at which Virchow presided, he had given a summary of them to the medical profession. Having given a brief account of the comma bacillus and its characteristics, as described by Koch, Dr. Flint went on to say that the latter had not hesitated to express his conviction of the potential agency of the organism in such words as these: "For my own part the matter is proved that the comma bacilli are the cause of cholera." That the comma bacillus was a suitable organism could not be doubted, since it had been successfully cultivated not only by Koch, but by a number of other investigators.

The grounds on which Koch based the hypothesis that this microbe was the causative agent of cholera were: —

First, because it was found to be present in all well-marked cases of the disease, and,

Second, because it was never present in the healthy body, or in cases of any other disease except cholera.

In the hundred cases of cholera in which he had looked for it he had not found it wanting in a single instance. The experience of the French government Commission, with Strauss at its head, which had also been sent out to Egypt in 1883, was somewhat different. In twenty-four cases examined by them the microbe was present in greater or less abundance in all except three. In these three it was present in such very small numbers that the Commission reported that they did not feel authorized in assigning this as the essential cause of cholera. Within a few days Dr. Flint said he had seen in the *Lancet* of September 20th an article by Mr. Timothy Lewis, assistant professor of pathology in the Army Medical School, in which he claimed to have discovered that comma-like bacilli identical in size, form, and in their reaction with aniline dyes, with those found in choleraic dejecta, were ordinarily present in the mouth and fauces of perfectly healthy persons. It did not appear that the culture-test had been applied in the case of those bacilli found in the saliva; and, at all events, the observations of Mr. Lewis would soon be confirmed or refuted by those of other investigators.

Granting, however, that Koch was correct in his two hypotheses, mentioned above, that the comma bacillus was always present in cholera, and that it was never found except in cases of this disease, it would be logically certain that there was an essential pathological connection between the disease and this micro-organism. Still it would not follow that the latter was the causative agent of cholera, since it might be a result, and not the cause, of the disease. The crucial test of its causative agency would be inoculation. If inoculation could be demonstrated the proof would be absolute; but Koch, as well as the members of the French Commission referred to, had failed in their efforts to secure this proof. In the same number of the *Lancet* in which Mr. Lewis's communication had appeared, however, there was published an account of the experiments made by two Swiss physicians, Rietsch and Nicati, in the laboratory of the Pharo Hospital at Marseilles, by instructions from the French government, in which it was stated that they had successfully inoculated a number of guinea-pigs, dogs, and rats with cholera. The guinea-pig was found much more susceptible to the disease than any other animal.

Having discussed still further the probable relations between the comma bacillus and cholera, Dr. Flint remarked that the disease, except in India, was an exotic one, and it was, therefore, much more probable that cholera was caused by the microbe than that the latter was simply a result of the disease. Koch had shown that the comma bacillus was short-lived, and it was well known that cholera was a very short disease. Moreover, the microbes were found most abundantly in the earlier stages of the disease, and rapidly diminished as time elapsed. Could the fact be shown that the comma bacillus gets into the system before the symptoms of cholera are developed the proof of its causative relation to the disease would be as clearly established as if the point of inoculation could be demonstrated, and Koch had found some evidence apparently to this effect when he was in India. During a local epidemic of cholera he found that the water in a tank used by the people for drinking and other purposes contained a large number of comma bacilli, and that the disappearance of these micro-organisms from the water coincided with the subsidence of the epidemic. Moreover, he could detect no comma bacilli in the water-supply of adjacent localities which were free from cholera at the time he visited them. The whole question of the parasitic origin of this disease, however, was still *sub judice*, and a proper sense of conservatism ought to lead us not to accept the investigations and conclusions of Koch until they had been con-

firmed by the researches of a sufficient number of expert observers. Still, in his own mind, Dr. Flint said he had little doubt that the truth of the doctrine would eventually be conclusively demonstrated. If this were the case it would only establish a hypothesis that had been for a considerable time anticipated in the medical world, and in this connection he quoted a passage on the relation of the germ theory to cholera in the fifth edition of his own work on the Practice of Medicine, published in 1880.

It was not to be denied, he continued, that there were considerable difficulties in reconciling Koch's views with certain facts in clinical experience, especially those relating to the diffusion and transmission of the *contagium vivum*. If the causative micro-organism was taken into the system in the ingesta it was difficult to explain the occurrence, almost simultaneously, of cases at a distance from each other, as well as the immunity of a large number of individuals exposed to the danger of infection, and the development of the disease in some whom we would naturally expect to escape. Much the same difficulties were met with in accepting the doctrine that tuberculosis was due to a specific microbe.

But, granting the truth of the parasitic origin of of cholera, what bearing would this have on treatment? This was certainly a question of great practical importance, since we were liable to have an outbreak of the disease in this country at any moment. So far as our present knowledge went there was no agent capable of destroying the parasite in the intestines without being toxical to the patient, though it was quite possible that such an agent might yet be discovered. Clinical experience had shown, however, that there was no disease which could be controlled with greater ease than cholera. The remedies *par excellence* for it were opium and complete rest, and if any case of it were taken in time the further development of the disease could be prevented with almost absolute certainty by these means. Dr. Flint said he could speak from personal knowledge on this point, as he had had a pretty large experience in several epidemics of cholera which had visited this country. Exactly what the modus operandi of the opium was in controlling this disease he was not prepared to state. He could only say that it was one of those instances, not very rare in practical medicine, of an important therapeutical truth which could not be satisfactorily explained in our present state of knowledge.

The next question to be considered was the bearing of this doctrine on the prevention of cholera, a point which was of even greater importance than the treatment. It was probable that the detection of the comma bacillus in the dejecta of patients before cholera had become epidemic would prove of great service in enabling us to check outbreaks of the disease at the very beginning, and would also furnish a means for making a differential diagnosis between cholera and cholerine, which was often a matter of very considerable difficulty. Wherever cholera appeared the complete destruction of the parasite directly it left the body could be secured, and by this means every case of the disease would be rendered sterile. Koch had proved that the cholera microbe was readily killed by drying, while cold somewhat diminished its activity, but did not destroy its vitality. The local conditions under which the parasite would thrive best outside the body were not definitely known, but there could be no doubt whatever that filth was very favorable to its development. Inside the body Koch had shown that the acidity of the gastric fluids was inimical to it. In order that an individual should contract cholera it was probable that there should be a predisposition or susceptibility to it, as was the case in tuberculosis, but, as in regard to that affection, our knowledge concerning the matter was as yet incomplete.

Dr. Flint then spoke of the very successful manner in which the epidemics of cholera in New York in the years 1866 and 1867 were stamped out by the energetic efforts of the Board of Health, and said that the efficiency of the measures adopted seemed to afford a certain amount of confirmation of the truth of the parasitic doctrine. These measures were carried out with admirable thoroughness by the late Dr. E. B. Dalton, a man of great promptness of action and executive ability, and under his direction there were a number of special sanitary inspectors, who visited every case the moment it was reported, and a large disinfecting corps, composed entirely of men who had lately served in the army during the war, who were kept in the state of readiness and discipline that the members of the fire department now are. The consequence was, that while there were 362 cases in the year 1866, in not a single instance did the disease spread proximately beyond the house where it was found. In 1867 there were a much smaller number of cases, and the disease was very readily controlled. Dr. Flint then said that it was his belief that never before or since in any country in the world had measures for the suppression of a dangerous epidemic been so successfully carried out. The history of the outbreak of cholera at that time showed that it was a disease which could certainly be stamped out, and he did not hesitate to say that if the same means had been adopted in the recent epidemics at Toulon, Marseilles, and Naples thousands of lives might have been saved. He also expressed the opinion that if the disease should again make its appearance here, it would rest entirely with the authorities whether it should become epidemic or not.

In conclusion he remarked that this was a most important era in medicine, since he believed that it would be to the present epoch that posterity would look back as the time when those signal discoveries were made which led to the final adoption of the parasitic theory of the origin of all infectious diseases. Was the medical profession in this country to have an active share in this great work of investigation and in these brilliant discoveries, or was it to be content to wait patiently until the announcements of the results of their labors were made by the scientific men of Europe? There was certainly no lack of ability on the part of American medical men, but it seemed to him that there was, at all events, a certain want of self-reliance and energy. At the same time it could not but be granted that there were difficulties met with here which did not exist in Europe, since the government did not afford any facilities or encouragement for investigation, as was the case there. In this country the profession would have to look to private liberality for its encouragement, and in this connection he alluded to the recent gift of $50,000 by Mr. Andrew Carnegie for the pathological laboratory at Bellevue, and of half a million by Mr. William H. Vanderbilt to the College of Physicians and Surgeons. One of the greatest benefits of such donations, he thought, was that it tended to give pri-

vate beneficence a direction toward the advancement of medical knowledge and education.

A few remarks were then made by Drs. E. G. Janeway and C. A. Leale, and also by the President, Dr. William Detmold, who thought that as papers were to be presented on the same subject (by Drs. Janeway and Leale) at the next meeting of the Association, it would, perhaps, be better that further discussion of Dr. Flint's paper should be postponed until that occasion.

PHILADELPHIA CLINICAL SOCIETY.

G. Belton Massey, M. D., Reporting Secretary.

Stated meeting, held September 26, 1884.

Dr. Clara Marshall read a report of two cases of Imperforate Anus, with Recto-Vaginal Fistulæ, in the Adult. The paper was reserved for publication by the reader.

A case of

Atresiæ Vaginæ with Retention of Menses

was reported by Dr. E. E. Montgomery. Miss F., aged forty-four, single, of healthy parentage, was brought to my office July 5, 1884, by Dr. Sibbald, of Wissahickon, with the following history: She commenced menstruating at sixteen, and continued without disturbance until her thirtieth year. Two years previously she had fallen upon a curbstone, receiving quite serious spinal injury, which lasted a year, when she fully recovered. The menstrual periods, which were always regular, lasting from three to four days, normal in quantity and color, at thirty became painful. Since then the pain has been constant, and increasing with each period. The discharge now lasts from seven to ten days, is of a dark bloody nature and offensive odor. During the menstrual intervals there is a continuous discharge of "corruption," as she calls it, necessitating the constant wearing of a napkin, and producing excoriation. All of these symptoms have been increasing during the past eight years, and she has been compelled to discontinue work a week or more at a time. She complains of a sensation of weight or pressure in the pelvis, attended with severe pain during defecation. There is no pain during micturition. Her nervous system has become much affected. Upon examination the vagina was found relaxed, and the external parts red and bathed with secretion. The vagina was about two inches long, ending above in a lateral cicatrix. No uterus could be felt. Upon withdrawal the finger was found bathed with a dark, thick, highly offensive discharge. The use of a Sims' speculum disclosed a cicatricial line running from side to side across the fundus of the sulcus, just posterior to which the membrane looked thinner. Slight pressure against this with a sound perforated it, and was followed by a profuse discharge of broken-down blood and pus. A pair of Ellinger's dilators was then introduced and spread to their full extent; over four ounces of the fluid flowed out. The cavity was then washed out with a carbolized solution. In this cavity above the cicatrix the uterus was found retroverted and firmly fixed, forming the roof. The cavity was dressed with carbolized glycerine on cotton. Subsequent treatment was conducted by Dr. Sibbald. He informs me that there has been no difficulty since, and that she now feels perfectly well.

Dr. W. H. Parish. That the treatment adopted in this case was proper the results showed, though it was not in accordance with the treatment directed by the text-books. We are there told to puncture the cavity with a trocar and draw off the confined liquid drop by drop. This is undoubtedly wrong, and its disadvantages have been demonstrated in my own practice. The crucial incision is undoubtedly best.

Dr. Collins related the details of a case treated in the manner of the text-books by exploratory needle, trocar, and drop-by-drop drainage. The cartilaginous membrane acting as septum was one and a half inches from the vulva, and probably congenital. A crucial incision was made after drainage, and the corners cut off, and no further trouble was experienced by the patient.

Dr. Montgomery, in closing the discussion said: As Dr. Parish has said, the free incision is best, though it was precipitated in the case related by an opening occurring during examination. The danger of septicæmia is certainly increased by a small opening. A particular point of interest in this case was the lateness in life and the time that elapsed between the injury and the retention.

Recent Literature.

Henke's Atlas of Surgical Anatomy. A Series of Plates illustrating the Application of Anatomy to Medicine and Surgery. Translated and edited by W. A. Rothacker, M. D., Pathologist to Cincinnati Hospital, etc. Cincinnati: A. E. Wilde & Co.

We are of the opinion that the translator has done a true service to the profession by the reproduction of this atlas. The original appeared some years ago, in advance of the text which was recently completed, and the reviewer well remembers recommending it to a medical friend in want of a good atlas for general use. The case of this gentleman was that of scores of professional men who want to see what structures are to be found in any particular region, and in what order they occur. They can refer to atlases of descriptive anatomy in which the various tissues are represented beautifully dissected, in which the ramifications of nerves or arteries can be followed, but only successively, which, in short, give no comprehensive view; or they may turn to frozen sections which, though true, give too limited views, and require too much study to be satisfactory. Between these extremes is the work before us, a happy combination of sections and dissections, showing many original and instructive views. The treatment is perhaps at times rather too diagrammatic. There would be considerable practical difficulty in cutting out of muscles the regularly shaped pieces with sharp edges, as appears to have been done, but the picture gains in vigor by this treatment, and the point is shown all the more emphatically. We particularly fancy some views of the abdomen in which certain parts of the intestinal canal have been removed so as to show the arrangement of the mesenteries and the position of deeper parts. Our most serious criticism of Henke's work is that he seems to have ignored the fasciæ almost entirely.

In the work before us the plates are of varying merit, some very good, others, we regret to say, of rather indifferent execution. The figures are not as

large as in the original. The names of the parts are clearly printed around the figure, and there is little difficulty in identifying them. We regret that Dr. Rothacker should have thought it advisable to change the adjective in the title from *topographical* to *surgical*, for, to our mind, one of the chief merits of the work is that it demonstrates that there is much in topographical anatomy that is not surgical. We should not close without a word of commendation of the solid binding and the good paper. T. D.

The Physiological Factor in Diagnosis, a Work for Young Practitioners. By J. MILNER FOTHERGILL, M. D. New York: William Wood & Co. 1883.

This volume of 250 pages crown octavo, from the prolific and facile pen of Dr. J. Milner Fothergill, is scarcely more than an expansion of the two little numbers of the Student's Aid Series, published by G. P. Putnam, in 1881, on Diagnosis. Of those numbers the first part, on Semeiology, was by Dr. Fothergill, and the second part, on Physical Diagnosis, by Dr. Thorowgood.

Dr. Fothergill's style is agreeable. Many of the hints which he gives have an undoubted value for young practitioners, who will be apt to find their ignorance on such subjects in direct proportion to their previous assiduity in the laboratory and lecture room, and some will profit by such a book as the one before us who would be repulsed by "sterner stuff."

The Pedigree of Disease, being Six Lectures on Temperament, Idiosyncrasy, and Diathesis, delivered in the Theatre of the Royal College of Surgeons in the Session of 1881. By JONATHAN HUTCHINSON, F. R. S., etc., etc. London: J. & A. Churchill. 1884.

Mr. Hutchinson's name, like the stamp on a coin, is of itself a guarantee of value to that which appears under it. These lectures, now published in book form, making a thin octavo volume of 140 pages, with index, were, as the title informs us, originally delivered, three years ago, before the Royal College of Surgeons, and appeared at the time in the *London Lancet*. With a few emendations they are published as originally delivered.

The methods of Darwin, to whose memory Mr. Hutchinson inscribes these pages, are followed in dealing with some of the problems of disease, methods which Sir James Paget has recently shown the fruitful possibilities of in this same direction, and which Mr. Francis Galton has made so suggestive in his treatment of sociological and physiological problems. One can hardly read what the writer actually says without being incited to further reflection and investigation in the direction pointed out, which we regard as higher praise than to bestow the too common epithet of "exhaustive treatise," a phrase which should rather be rendered as "laborious compilation."

The lectures are six in number, and group themselves in general around "the study of those differences between man and man, of which, for the most part, physiology takes no cognizance, but which may yet prove of much importance in modifying the processes of disease." The subjects, in the order presented, are temperament, idiosyncrasy, diathesis.

The "young practitioner," if intelligent, may profit by these suggestive essays, and old ones, however experienced, will find mental food which they will relish.

A New Method of Recording the Motions of the Soft Palate. By HARRISON ALLEN, M. D., Professor of Physiology in the University of Pennsylvania. P. Blakiston, Son, & Co. 1884.

Dr. Allen's method consists of passing a straight rod through the nose from before backward until it impinges against the roof of the naso-pharynx. In this position, he says, the rod is not influenced by any motions of the soft palate; but if the end of the rod which remains without the nostril be raised so that the rod be brought in contact with the anterior border of the nostril, the pharyngeal end of the rod will lie in a position which will cause a decided motion to be transmitted to it when the soft palate is raised. The subject being seated before a kymographion, which had been previously prepared with smoked paper, it was ascertained that when the free end of the lever touched the cylinder, at a time when the latter was in motion and the soft palate was raised, that a distinct tracing appeared upon the cylinder, and that the differences between the long and short sounds of the vowels were found to correspond with the curves made by the rod upon the kymographion.

Dr. Allen calls his instrument the palate-myograph. Tracings are given of the movements of the palate as it is raised in the articulation of different sounds, and in the acts of swallowing, coughing, hawking, etc. The curves show considerable variation, and are not the same for the same sounds in all individuals. They show that the palate is raised once only for some words, twice for others, and three times for others. The author points out the sources of inconstancy of the curves, but they are not sufficient, it is thought, to invalidate the claim of accuracy for the method. It is hoped that the palate-myograph will prove of use in studying the mechanism of the soft palate in disease as well as in health, also in stammering, and in determining the degree of degeneration of the levator-palati muscles in progressive dry aural catarrh. It has even been suggested by competent critics that it may be made available for the comparative study of language, for the instruction of the deaf, and for the promotion of a system of logography or short-hand writing. We hope the palate-myograph will have this brilliant future, and prove useful in all these different channels. It is certainly an ingenious instrument of precision, and will be of some real practical value. F. H. H.

— A "mountain of alum" is said to have been discovered in New Mexico. It extends over a superficial area of more than a square mile, and rises in some places to an elevation of seven hundred feet above the bed of the river. Most of the alum appears to be in an impure state, tasting strongly of sulphuric acid, but, nevertheless, some of the cliffs are said to show immense quantities of alum in a marketable condition.

Medical and Surgical Journal.

THURSDAY, OCTOBER 30, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 Park Street, Boston, Mass.

DILATATION OF THE STOMACH.

There is no organ in the body whose well being and efficiency are more important to the general economy than the stomach, and at the same time there is none which is more abused. There is no class of diseases more common in this country than the functional or true dyspepsias, and no class whose ætiology is more difficult to disentangle, whose treatment is more difficult to direct and control.

For a long time the term "dyspepsia," like the term "bilious," was a reproach to the knowledge of the doctor, and a refuge for the ignorance of the layman. The former is no longer contented with a diagnosis which achieves nothing more than the rendering of two English words into one Greek word, and the patient himself desires to know something of the cause as well as of the symptoms.

Antiseptic surgery has robbed the peritonæum of the respect in which it was formerly held, and the surgeon no longer hesitates to attack mechanical obstructions of the stomach or intestines through the abdominal walls. We are no longer dependent upon an almost unique accidental traumatism for studying the chemistry of the stomach. In addition to increased facilities for observation we have besides in the advances of physiological chemistry, in the more careful application of the microscope to tissue changes, in the bolder use of the stomach-sound and tube, in the application of auscultation and percussion, and in the more accurate knowledge of nerve changes, distribution and influences, a far more scientific key to the interpretation of our observations upon the gastric tissues and functions, and consequently of their derangements.

Dyspepsias are being classified not arbitrarily but according to structural and chemical changes, and the name itself is more properly limited to functional disorders, to chemical derangements of the gastro-intestinal tract; these are true "dyspepsias." Mechanical obstructions are responsible for many difficult digestions, but these should not be classed in the same category as the "true dyspepsias," and again these latter will certainly before long be still further subdivided. We stand as yet only on the threshold of such advances.

In his volume on Dyspepsies Gastro-Intestinales, Monsieur Germain Sée made an important contribution to the elucidation of these functional dyspepsias, and we find him again, in company with M. Mathieu as a collaborator, contributing an interesting study to the cause, diagnosis, and treatment of a very common but not sufficiently recognized or well understood gastric phenomenon — dilatation.[1]

Dilatation of the stomach is much more common than is generally supposed, and results from a variety of causes besides the strictly mechanical ones of obstruction and excessive ingestion of food or drink — polyphagia. MM. Sée and Mathieu recognize in a certain number of cases lesions appreciable to the microscope which afford a sufficient explanation of an exaggerated dilatation of the stomach, such as fatty degeneration or the interstitial cirrhosis of those addicted to alcohol. Dilatation may ensue in a passive manner in debilitated individuals, in those who are exhausted by a general cachexia, as a result of the debility, but particularly from loss of action on the part of the muscular walls of the abdomen. Occasionally paralysis of the stomach is the only assignable cause, possibly the result of epigastric or general traumatisms. Simple dilatation of the stomach occurs most frequently in persons who present a peculiar general neurosis. It occurs as a sequence to crises which seem to indicate the successive and alternate occurrence of a special state of spasm and atony of the gastro-intestinal motor system. These crises, which are frequently painful and sometimes accompanied by diarrhœa, are repeatedly produced by an occasional or general cause, such as depressing emotions, moral shocks, or by a local cause, as excess, insufficiency, or bad quality of the alimentation. Constipation and flatulence seem to play a considerable part in the mechanism of the development of these gastro-intestinal troubles in which gastric ectasis predominates. Dyspepsia, rarely preceding dilatation, follows it frequently, and then seems to be characterized by the presence in the urine of an unusual quantity of peptones. In any case a permanent dilatation is not reached until after prolonged alternations of spasms, giving rise to pain and diarrhœa, with atony, giving rise to distention. These pathogenetic considerations have a direct bearing upon the study of the symptomatology of simple gastric dilatation, upon its diagnosis, and upon the treatment of the complex train of symptoms accompanying it. In the pursuit of these we will follow MM. Sée and Mathieu in another number.

MR. VANDERBILT'S GIFT TO THE COLLEGE OF PHYSICIANS AND SURGEONS OF NEW YORK.

It is but a few weeks ago that we spoke of the reasons why medical men should remember the wants of their own profession, and said that medical schools in this country needed assistance because they were deprived of the government subsidies, which sustain similar institutions in certain other countries. We also tried to show that in no way could the whole community be more benefited than by fostering those things which tend to educate and elevate the medical profession. A

new era has been inaugurated since we wrote those words. Not that medical schools as a body are less needy, but the immediate wants of one school have been provided for by the gift of half a million of dollars; which amount has been given by Mr. William H. Vanderbilt to the College of Physicians and Surgeons of New York. The importance of the gift is not confined to the college which is the recipient of Mr. Vanderbilt's munificence, but its good effect will be widely felt in drawing attention to the fact that medical colleges are proper objects of benevolence. It will have an influence in drawing towards them additional gifts from the charitable until private munificence shall leave no chance for us to speak with even a show of regret of the want of governmental aid. The modern good Samaritan will not be content to bind up the wounds of a single individual, but will bestow his collected oil and wine so that it may be used for the training of men whose daily duty it shall be to attend to the relief of many unfortunates. Even a single college well endowed, so that it need have no thought whatever of the amount of its tuition fees, so that its whole ambition will find scope in providing the best possible education, must have a beneficial effect upon the profession, not merely by the character of its graduates but by stimulating other and feebler institutions to better things.

There is no immediate prospect that the laws of all the States will discriminate between physicians who have been fitted for their work and those who have not. To many men it seems of more importance that there should actually be a difference than that the distinction should be legally declared to exist. That the distinction is not always clearly marked is in great measure the fault of the medical schools which are too ready to receive as students men who are unfit to be so received and to graduate men who are unfit for graduation. Our medical schools have grown from small beginnings, and in few things is the youthfulness of our country more apparent than in the condition of these schools. The great bar to their improvement is their need of money. By the munificent gift of Mr. Vanderbilt the New York College of Physicians and Surgeons becomes, we believe, the best endowed institution now open to students. With our high ideal of the medical profession we doubt if the donor could have done a wiser act or one better calculated to benefit the community at large, and we trust it will be so wisely administered that the greatest good possible will be attained.

It is believed that a part of the donation will be used in the erection of a new building in the block between Fifty-ninth and Sixtieth Streets and Ninth and Tenth Avenues, in close proximity to Roosevelt Hospital, from which it will be separated only by Fifty-ninth Street, and within convenient access, by the elevated and surface railways, with the distant hospitals.

— The Syrian College, Beyroot, has tendered to Dr. W. P. Manton, of Detroit, the chair of Gynæcology and Obstetrics in the Medical Department of that college.

MEDICAL NOTES.

— An astonishing ruling has, according to the reports of the German medical journals, been recently made by the courts of that country on a point of alleged malpraxis. In April of the present year a serving man was wounded in the chest with a knife, and was treated by a practitioner without antiseptic precautions. The man died from septic poisoning, and the practitioner was arraigned on the charge of culpable homicide, which was upheld by the magisterial court on the ground that a medical man should be so far abreast with modern science as to avail himself of the recognized rules of treatment, and that in the case in question the practitioner should have been aware that the procedure adopted by him might lead to the death of his patient. The Reichsgericht, being appealed to, confirmed this decision. In view of the wide differences of opinion still obtaining among practitioners in England and America regarding so-called "Listerism," one cannot help thinking what havoc would be made with professional reputations and pockets were such a cause recognized in either of the latter countries as a fit ground for legal interference.

— However it may be regarding the fertility of the French people in their native land, the increase of the French population in Canada is most remarkable. A Montreal paper states that the French inhabitants of the Province of Quebec numbered 3000 in 1653. In 1763 they were 60,000. Since that date there has been no immigration from France, and many of the French have been tempted away to the States. Yet in spite of this fact the French population of the province of Quebec is now over a million. With their increase the English have diminished. The French in all the Canadian provinces number about 1,300,000.

— The Society of the Red Cross has instituted some experiments with the electric light as an aid in the search for wounded on the field. An exhibition of the experiment was made during the recent meeting of the Society at Geneva, but proved a disappointment to the spectators on account of the full moon which was shining at the time.

— An officer of the British army in India was recently, while staying at Kangra, bitten by a cobra in the hand. With great fortitude he seized his gun and blew off the finger that had been bitten. Nevertheless, when medical aid arrived he was almost insensible, and it was only by keeping him walking about all night and administering large doses of brandy and ammonia that he was pulled through. Recovery from a cobra-bite is very rare.

— The female medical students in Paris have organized a movement looking to their admission as internes in the Paris hospitals, or rather to being allowed to compete therefor. The appointment is for four years, and in the largest hospitals its responsibility and arduousness are such as to tax severely the powers of the male incumbents. But *place aux dames*.

— The *Medical and Surgical Reporter* says that during the cholera season of 1873 a French physician in Nashville declared that he never lost a cholera pa-

tient. Shortly afterward, having gained some notoriety by this assertion, he was summoned to attend a man named White. The neighbors were anxious to see the result of the Frenchman's treatment, and whenever the doctor was seen leaving White's house numerous inquiries were propounded. "How is your patient, doctor?" was asked one morning. "Ze man is dead." "What! thought you never lost a case of cholera?" "Zis was ze first case I had. You not expect a man to lose one case before he get him. I cure ze man of ze cholera, but he die of ze weakness."

— Dr. Thomas exhibited at the recent meeting of the American Gynecological Society a mediæval instrument for preventing coitus. The apparatus resembled the well-known ivory affair that was furtively exhibited to tourists at the Hôtel de Cluny. It consisted of a jointed iron belt, to encircle the hips, to which a rigid strip of iron was connected before and behind, somewhat after the manner of a T-bandage. This strip of iron was widened where it passed over the vulva, and at that place there was a slit-like fenestra with a serrated edge, the teeth being bent somewhat outward. At the situation of the anus there was another perforated expansion, circular in this instance, and that opening also was serrated. The whole was covered with ancient-looking velvet. The strip of iron which passed between the thighs was hinged to the pelvic girdle in front, but behind (perhaps to add to its discomfort) it was secured with a lock. The original lock was a remarkable antique, and bore the emblems of high nobility, — perhaps royalty. On that account his friend had desired to keep possession of it, and therefore he (Dr. Thomas) had replaced it with a small modern padlock.

— Some observations as to the relation between deaf-mutism and consanguineous marriages, especially those of first cousins, were made last year by Dr. C. A. Cameron, President of the Subsection of State Medicine of the Academy of Medicine in Ireland. On the whole, the evidence seemed to show that the effects were somewhat injurious. The statistics in reference to mutes published in the *Irish Census Reports* for 1881, and the previous decennial reports, were closely examined by the author. It appears that in Ireland, in 1881, there were 5136 mutes, of whom 135 were the children of first cousins. The author endeavored to ascertain the proportion of the population who were children of first cousins. He ascertained that amongst nearly 8000 persons the proportion was only 0.57 per cent., or less than one fourth of the rate amongst deaf-mutes. As the statistics were in great part collected amongst Protestants, the author believed that there was not in all Ireland one person in two hundred the offspring of first cousins, as marriage between such persons was very rare amongst Catholics, who formed three fourths of the population of Ireland. The general conclusion arrived at was that consanguineous marriages were a cause of deaf-mutism.

— The *Lancet* remarks that Signor Silvio Plevani, Director of the Hospital Frate Bene Fratelli, has published (May 28th) in the *Gazzetta degli Ospitali*, a paper on The Economical Preparation of Some Antiseptic Dressings. He states that tow, which is a very cheap, residual material, can be used for all surgical purposes instead of absorbent cotton, when prepared according to the following directions: Boil the tow for some time in lye made with wood ashes, or with a ten per cent. solution of carbonate of sodium; then wash it repeatedly in water. The tow thus deprived of grease is immersed in a ten per cent. solution of chloride of lime, and kept in it some hours, with occasional stirring, until it has become perfectly white. It is then washed thoroughly in pure water until the liquid squeezed from it is perfectly limpid. Drying and carding complete the process.

— At the Congress of the Sanitary Institute of Great Britain, recently held in Dublin, a Mr. Maguire read a paper in which he introduced a valuable sanitary maxim, which, however, being couched in the language of the country, took the following peculiar turn: "The best way to prevent what is past is to put a stop to it before it happens."

— "Eph, wha's de reason you doan' want Mass' Blaine 'lected?"

"'Cause he ain' no hones' man."

"Did n't he 'splain dem Mulligum lettahs?"

"Yaas."

"An' did n' he say he war marrud twy'st?"

"Yaas."

"An' doan't he swar he neber owned no lan' in Ohio?"

"Yaas, but he ain' no hones' man."

"Wha 's de reason?"

"Ain' 'e got Bright's disease?"

"S'pose 'e hes?"

"Waal, w'y doan' 'e gib it back to Bright, den?"

Correspondence.

A CORRECTION.

Mr. Editor, — In the *Boston Medical and Surgical Journal* for October 9th, on page 347, I find the following paragraph: —

"Dr. Van de Warker had seen, in consultation, a case which had been thirty hours in labor, in which the pelvis was filled with a fibroid of the posterior cervical wall. He advised enucleation, but was overruled. Cæsarean section was performed and the mother died of shock. The autopsy showed that enucleation could have been easily performed. In this case the child was saved."

The facts of the above case are these: I was notified on the evening of the 16th of June, 1881, that the patient was beginning to have labor pains. I called about ten A. M., but found her so comfortable I thought that labor had not yet commenced. About two P. M. of the 17th the husband came for me. On arriving at the house I was informed that "the waters had broken." I made an examination, and found what I thought to be the head well down in the middle straits, but could not detect the os. In a little time I made a second examination, and after giving a few whiffs of chloroform introduced my hand well up anteriorly,

when I was able to feel the os not much dilated. The pains not being very strong I did not examine again for some time. At the third examination, using both hands, I found a tumor above the pubes, and through the os detected the fontanelle; then I knew I had a more formidable case to deal with. Dr. Mercer was sent for, and under chloroform he examined the patient. I had previously tried to force up the tumor, thinking that by dislodging it I might turn should the head not engage. I now applied the forceps, and together we endeavored by various means to push up the tumor into the abdominal cavity and bring down the head. After successive efforts and failures we asked for another physician. Dr. Van de Warker was sent for, and arrived before nine A. M., seven hours after my night visit when labor had only fairly set in.

Recounting our experience to him, he said, Why not aspirate? We tried, but did not get a drop of fluid. Then one of us proposed Cæsarean section; it was conceded by the others to be the only resource left. The family were informed, and a ready consent given. Leaving Drs. Mercer and Van de Warker with the patient I started out to get the instruments required and invite a few medical friends to assist.

About noon, the patient being anæsthetized, and the table ready, Drs. Pease, Van Duyn, A. C. Mercer, Cook, Slocum, and Stevenson were admitted to the room. Dr. Pease examined the patient for the other physicians, and all deciding the Cæsarean section to be the only feasible procedure, I performed the operation. It was asked, before the abdominal wound was closed, whether it were best to remove the tumor. On examination several thought the pedicle too short and thick, and wishing to give the patient every chance it was left *in situ*. She rallied nicely from the chloroform, and I stayed with her for the succeeding eighteen hours, during part of which time she caressed her baby, complained very little of pain, took what was given her, and rested under an anodyne. She was not aware of the operation she had undergone, as I did not wish to alarm her. Some time after I had left the house some injudicious friend was allowed into the room who described to her (no doubt very graphically) the terrible ordeal she had passed through; she fainted, rallied a little, but the shock was too great, and twenty-five hours after the operation she quietly passed away.

At the autopsy, performed twenty-four hours after death by Drs. Jacobson and Elsares, Drs. Mercer, Van de Warker, Pease, and myself being present, the tumor was found to be egg-shaped, attached by a round pedicle three quarters of an inch long, one inch in diameter, to the posterior wall of the uterus, five (5) inches from os, the entire length of womb being nine (9) inches. The natural position of the tumor had been transverse, but its attachment having been a little nearer the smaller end had allowed the heavier extremity to dip down into Douglas' cul de sac. The dimensions of the tumor were, long circumference fourteen (14) inches, long diameter six (6) inches, circumference of large extremity twelve (12) inches, diameter four (4) inches. On a section being made into it the walls were found to be over one inch in thickness, hard, and unyielding; the interior resembled that of a kidney.

The capsule and tissue of the tumor were so intimately blended together that enucleation could not have been performed. From its size and consistence it would have been impracticable to have attempted ablation per vaginam. The only way to have gotten at it would have been through the abdominal walls.

In closing I would state that the specimen is now in the Histological Museum of Syracuse University.

ROBERT ABERDEIN.

SYRACUSE, *October* 20, 1884.

Miscellany.

A FRACTURE OF SKULL OF MEDICO-LEGAL INTEREST.

IN the *Edinburgh Medical Journal* (October) Mr. Nasmyth gives an account of a case having somewhat remarkable clinical symptoms, and containing important suggestions from a medico-legal point of view: —

A man was found lying dead at the side of a disused toll-house near to an inn. He was cold and stiff, his clothes soiled, and saturated with water. The night was a terribly stormy one, and during that night a great many deaths from exposure occurred, as was learned from the newspapers. The expressed belief of those who found it was that death was due to exposure. It was casually learned, however, that on the previous night a man had fallen down-stairs in the inn near to where this man was found; that he was insensible for a time, and blood came from his nose and ears or ear; inquiry showed that this person was identical with the dead man. The body was found to have clotted blood in the left ear, marks on the face, and the pupils of both eyes were widely dilated. An examination was ordered with the following result: —

Body said to be of a miner, aged about forty; height five feet ten inches; body cold; rigor mortis marked; face scratched over left cheek bone; blood in left ear; pupils widely dilated. On dissecting back the scalp, extensive effused blood found over left parietal and temporal bones. Knife grated against the skull, and on investigating a fracture of skull was found. On removing skull-cap an extensive effusion of blood was found corresponding to situation of left parietal and temporal bones, and reaching up to longitudinal suture of skull. On removing brain effused blood found at base, reaching forward to anterior lobes, posteriorly to medulla, and between the cerebrum and cerebellum. The fracture could now be seen distinctly, and was quite open at one place, allowing a scalpel to be inserted into the opening, and to pass into auditory meatus. The course of the fracture was this: Beginning in the petrous portion of the left temporal bone, near to the articulation with the sphenoid, passed into the auditory meatus, right across the squamous portion of temporal bone, up through the left parietal, and backwards in an irregular curved course. The total length, as nearly as could be measured, was about eight inches.

The following evidence as to the case was then obtained. The dead man had fallen from a height of about six feet, on the Saturday night, in the inn; he fell face forward, and his face or head alighted on the hard stone floor. He lay insensible for some minutes, but regained consciousness so far and was able to walk with assistance to one of the rooms in the inn, where cold water cloths were applied to his head and in a short time he was able to converse and smoke a pipe. He remained in this condition for at least an hour and a half, and at the closing hour he left with others who were in the house. It was noticed that he stumbled

and fell, but was able to get to his feet again. No subsequent history could be obtained, and the finding of his dead body is the next point in the evidence.

The points of importance in the case are: (1.) The length of time the man lived after receiving his extensive and deadly injuries, taking for granted that the fall down-stairs was the cause; (2.) The stage of unconsciousness after the fall, the regained consciousness, again passing into the insensibility which preceded death, evidenced by stumbling and falling as he left the inn.

The writer's explanation of the above points is as follows: —

"The severe fall caused, in the first place, concussion of the brain, as well as fracture of the skull. This concussion explained the first unconsciousness, and as it passed away he returned to his senses, and then the effects of the fracture began, namely, hæmorrhage, which from the free openings of the fracture into the ear, and under the scalp textures, could escape externally, so that at first the brain was not pressed on; as the blood accumulated under the scalp it gradually offered resistance to the external hæmorrhage, and clotting occurring in the auditory meatus stopped this outlet, so that the full effects of the pressure would now be exerted on the brain, and the stumbling and fall at the inn door were the first symptoms of this; then the gradual increase of blood, at last reaching the medulla, as the clots there showed, put an end to existence."

CROSSING THE LEGS, AND THE MODE OF SITTING.

M. Delaunay, of Paris, has made an extended and careful investigation, an account of which is given in the *British Medical Journal*, May 10, 1884, to ascertain if, in the majority of cases, the right upper and lower extremity be crossed over the left, or the left over the right, and which side most persons incline to when in the sitting posture. According to M. Delaunay, certain breeds of dogs, such as terriers, Newfoundlands, and poodles, cross the right paw over the left. The Chinese and Japanese cross the left arm over the right. Europeans cross the right over the left. M. Delaunay observed, in the *crèches* and *salles d'asiles*, that infants under three years of age cross the left arm over the right, older children crossing the right over the left, sixty per cent. doing so at six years of age. Robust children cross the right arm over the left; the idiotic and weak, including those who are incapable of working, cross the left over the right. The Calmucks and Arabs cross the right over the left like the Europeans. A great many women cross the left leg over the right. Among the opera dancers some always cross the right leg over the left, but not one the left over the right habitually; the majority cross the left over the right or the right over the left indifferently. Robust children cross the right leg over the left earlier than their weaker playmates. Persons who cross the right leg over the left lean towards the left when sitting; those who place the left uppermost lean to the right. Hence, consistently with what might have been expected from what is observed in children with regard to crossing legs, until six years of age children lean towards the right, and afterwards towards the left. French schoolmasters, it would appear, try to prevent their pupils from assuming this position, believing that scoliosis results; hence they encourage or enforce the use of elbow-rests (*accoudoirs*), which oblige the children to sit straight, — a useless measure, according to M. Delaunay, as the position they choose is in conformity with the process of evolution. Tailors affirm that the back of a pair of trousers is always more worn on the left side than on the right. Left-handed people always sit towards the right. M. Delaunay concludes from these observations that the left brain develops previously to the right, and finally the right predominates.

PROFESSOR OSLER.

It has been for some time known that Prof. William Osler, of McGill University, has been a candidate for the Professorship of Clinical Medicine in the University of Pennsylvania at Philadelphia. On the 7th inst. a meeting of the Board of Trustees of this Institution was held, and it was immediately afterwards announced to Dr. Osler that he had been unanimously elected. We congratulate most heartily our *confrère* and hitherto colleague upon this mark of the high esteem in which his professional abilities are held by the teaching men of the United States. The position he now holds he never sought. It was, in fact, offered to him without any solicitation on his part. The selection, in our opinion, does his University infinite credit, as showing that they are willing to go even beyond the boundaries of their own country to find the best man to fill such important vacancies.

The profession of this city and of this country feel that they are sustaining a great loss in thus parting with one of their ablest, most zealous, and energetic members. McGill University feels keenly the removal of one of its best teachers, and the General Hospital one of the most active members of its staff.

We feel certain that Dr. Osler will be often heard of in his new and wider field of labor, where we wish him all the success and prosperity his undoubted merits deserve. — *Canada Medical and Surgical Journal.*

THE OIL-SPOT.

About ten miles to the south of the Sabine River, which forms the boundary between Texas and Louisiana, and about a mile from the shore, there exists a natural phenomenon known to sailors as "The Oil-Spot." In fine weather there is nothing remarkable to attract the attention of a stranger; but when an angry gale from the north-east sweeps the ocean, and great crested waves rise in battle array, this charmed natural harbor reveals itself. No visible boundary divides it from the tempestuous ocean around; but within a space two miles in length *the waters remain perfectly calm*, their only change being that they become turbid and red, as though the oil-bearing mud were stirred up from below. A broad belt of white foam and towering breakers marks where the mighty waves, with all the force gathered in an unbroken sweep of seven hundred miles across the Gulf, are suddenly arrested, and sink down, conquered and powerless, so soon as they come within the mysterious influence of this gentlest of rulers.

Unfortunately, this peaceful haven is very shallow; its depth is variously stated at twelve and eighteen

feet, so that only vessels of light burden can here take shelter. But to these, blessed, indeed, is the change of passing suddenly from the wild tossing of the outer ocean to the wonderful calm of this strange harbor, where the weary crew may rest as securely as though within an encompassing coral reef. Indeed, the stranger approaching this wall of breakers would naturally assume it to be caused by a dangerous reef, and would, as a matter of course, seek safety by steering away from it.

We believe that no scientific examination of this so-called Oil-Spot has yet been made. Sailors who have here found refuge state that the bottom is of a soft, soapy mud, into which they can easily push a pole to a considerable depth — a mud which, when applied to deck-scrubbing, is found to be exceedingly cleansing. — *From "The Oil-Supply of the World," in Popular Science Monthly for November.*

BLUE EYES GOING OUT.

As the outcome of sexual selection, says *Science*, blue eyes are to disappear, at least from Europe. So predicts Mr. Alphonse de Candolle, in his paper on Heredity in the Color of the Dyes in the Human Species, recently published in the *Archives des Sciences*. In investigating the subject of heredity, it occurred to De Candolle that the color of the iris offered the best outward and visible sign. It is conspicuous; it cannot be masked by artifice; after early childhood it does not vary with age, as does the color of the hair; and the character is, on the whole, distinct. For, according to him, there are only two sorts, — black, or rather brown eyes, and blue; gray eyes being reckoned as mere varieties of the blue. From the working-up of the statistics, in part from series of observations made for the purpose, it appears, that, when both parents have eyes of the same color, 88.4 per cent of the children follow their parents in this feature; and of the 11.6 per cent. of children born with eyes of other than the parental color a part must be attributed to atavism, that is, to intermittent heredity. But the curious fact comes out, that more females than males have black or brown eyes, in the proportion, say, of 49 to 45 or of 41 to 39. Next it appears that with different-colored eyes in the two parents 53.9 per cent. of the progeny followed the fathers in being dark-eyed, and 55.9 per cent. followed their mothers in being dark-eyed. An increase of five per cent. of dark-eyed in each generation of discolorous unions must tell heavily in the course of time. It would seem, that, unless specially bred by concolorous marriages, blue-eyed belles will be scarce in the millennium.

THE INJECTION OF A SOLUTION OF SALT IN ACUTE ANÆMIA.

A contribution to the study of saline injections, intra-venous and arterial, in acute anæmia is made by Dr. Thon, who has collected reports of thirteen cases, and published them in the *Australian Medical Gazette*. In six of these cases the cause of the acute anæmia was post-partum hæmorrhage. Five out of the six patients recovered completely, and the sixth improved temporarily, but died three weeks after the operation from perforative peritonitis. The remaining cases which called for injection were as follows: One of collapse, following partial extirpation of an ovarian carcinoma; one of collapse, after poisoning by iodoform; one of collapse through loss of blood during nephrotomy; one of anæmia from secondary hæmorrhage after resection of the knee-joint; one of hæmorrhage from carcinoma of the cervix uteri; one of collapse from severe compound comminuted fracture; and one from complete collapse and anæmia during abundant hæmorrhage from an ulcer of the stomach. Three of these seven cases, from various causes, were saved by the infusion of sodium chloride, and although the rest died, there was in every case material improvement, lasting for hours and days. The strength of the solution is recommended to be six parts of pure chloride of sodium to a thousand parts of distilled water neutralized by two drops of the solution of soda. A convenient method of administering it is to place it, after being warmed to 39° C. (102.2° F.) in a cylindrical glass jar. To the base of this jar a tube 80 c. m. (twenty-six inches) long is attached, ending in a transfusion canula, which is to be inserted into the vein. The fluid makes its way very readily into the latter. From a thousand to fifteen hundred centigrammes of the solution may be employed, although in some instances not more than five hundred were found to be necessary. The injection may be made into either the basilic vein or radial artery.

SUDDEN DEATH IN CHILDBIRTH.

Dr. William T. Lusk read before the Practitioners' Society of New York, at its meeting June 6th, a case of sudden death, which the reader believed to be due to surgical shock, and remarked that text-books on obstetrics assumed that it was not possible for a woman to die of shock in parturition, but from what he had observed he was inclined to believe that death in lying-in women was not infrequently produced by that cause.

The case was as follows: —

The patient was a primipara, healthy, and twenty-three years of age. Seen first January 1st of present year at seven A. M. Patient said pains had begun on previous afternoon, and she had paced the floor all night. She said that when in motion she found it easier to bear her pains. Examination: Extreme tenderness of vagina and cervix; cervical canal dilated by head; os extended, size of half dollar; head covered tightly by membranes; no pouch. At eleven o'clock little progress. Gave chloroform, and pushed up head so as to allow bag of waters to form. This manœuvre was followed by rapid dilatation. Head in twenty minutes on perineal floor. Forceps then urged. Patient wished "glory of having her baby herself." Waited at her instance until between one and two o'clock. Patient suddenly lost color, and seemed dazed when spoken to. Applied forceps to head at vulva. Easy extraction followed by some hæmorrhage, but the latter was quickly controlled. Patient's face showed signs of complete collapse. Stimulants, warm hypodermics of brandy, and hot tea were given at short intervals. Apparent rally. At seven P. M. went to dinner, thinking period of safety reached. Patient suddenly turned in bed, and pulse became very feeble.

There was a slight rally, and then came death. Absence of respiratory troubles excluded pulmonary embolism either from venous thrombi or from air. The associated symptoms were those of surgical shock, to which the patient was, probably, predisposed by the ante-partum exhaustion. The writer argued against the rejection of surgical shock among the causes of sudden death in childbed, holding that the entry of air into veins, embolism, and pulmonary thrombosis are insufficient to account for all cases.

Deaths reported 2441 (no reports from St. Louis, Cincinanti, and Pittsburg): under five years of age, 988; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 627, consumption 352, diarrhœal diseases 213, diphtheria and croup 201, lung diseases 177, typhoid fever 84, whooping-cough 41, malarial fevers 46, scarlet fever 20, measles 10, erysipelas two, puerperal fever one. From *malarial fevers*, Brooklyn 13, New Orleans 11, New York 10, Providence four, Philadelphia, Baltimore, and Charleston two each, Chicago and Nashville one each. From *whooping-cough*, New York 14, Baltimore six, District of Columbia five, Chicago and Boston four each, Brooklyn three, Nashville two, Philadelphia, New Orleans, and Lynn one each. From *scarlet fever*, New York six, Providence five, Brooklyn and Boston two each, Philadelphia, Chicago, Cambridge, Holyoke, and Newburyport one each. From *measles*, New York five, Philadelphia two, Brooklyn, District of Columbia, and Fall River one each. From *cerebro-spinal meningitis*, New York three, Philadelphia and Fall River two each, Milwaukee one. From *erysipelas*, Baltimore and Lynn one each. From *puerperal fever*, Milwaukee one.

Cases reported in Boston: typhoid fever 59, scarlatina 58, diphtheria 33, and measles six.

In 104 cities and towns of Massachusetts, with an estimated population of 1,366,324 (estimated population of the State 1,955,104), the total death-rate for the week was 17.62 against 17.84 and 18.58 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending October 4th, the death-rate was 20.1. Deaths reported 3379: infants under one year of age 1057; acute diseases of the respiratory organs (London) 184, diarrhœal diseases 281, fever 68, scarlet fever 59, whooping-cough 54, measles 37, diphtheria 37, small-pox (London 10, Birkenhead and Sunderland one each) 12. The death-rates ranged from 14.1 in Portsmouth to 31.4 in Halifax; Birkenhead 21.8; Birmingham 22.2; Bradford 20.4; Leeds 22.8; Leicester 24.4; Liverpool 22.1; London 17.2; Manchester 25.1; Nottingham 20.8; Sheffield 23.8. In Edinburgh 16.1; Glasgow 23.1; Dublin 26.3.

For the week ending October 4th, in the Swiss cities, there were 33 deaths from consumption; diarrhœal diseases 20, lung diseases seven, typhoid fever four, small-pox three, puerperal fever two, whooping-cough one. The death-rates were, at Geneva 12.2; Zurich 19.9; Basle 19.5; Berne 22.2.

The meteorological record for the week ending October 18th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY FROM OCTOBER 18, 1884, TO OCTOBER 24, 1884.

WOLVERTON, W. D., major and surgeon. Granted one month's leave of absence, to take effect when his services can be spared by his post commander. Paragraph 4, S. O. 211, Department of the East, October 16, 1884.

VICKERY, R. S., major and surgeon. During temporary absence of Major J. C. McKee, Surgeon U. S. A., Medical Director of the Department, in addition to his other duties, will assume charge of the office of the medical director. G. O. 34, headquarters Department of California, October 8, 1884.

WINNE, C. K., captain and assistant surgeon. In addition to his duties as post surgeon at Benicia Barracks, will also attend the sick at Benicia Arsenal, Cal. S. O. 122, headquarters Department of California, October 13, 1884.

HAVARD, VALERY, captain and assistant surgeon. Assigned to temporary duty at Fort Schuyler, New York Harbor, N. Y. Paragraph 2, S. O. 211, Department of the East, October 16, 1884.

STRONG, NORTON, first lieutenant and assistant surgeon. Assigned to duty at Fort Union, N. M. S. O. 198, Department of the Missouri, October 4, 1884.

PHILLIPS, JNO. L., first lieutenant and assistant surgeon. Transferred from Department of the East to Department of Dakota. S. O. 245, A. G. O., October 18, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING OCTOBER 25, 1884.

BLOODGOOD, DELAVAN. Promoted to the grade of medical director. August 22, 1884.

OBERLY, AARON S. Promoted to the grade of medical inspector. March 28, 1884.

WELLS, HENRY M. Promoted to the grade of medical inspector. August 22, 1884.

OBITUARY. DR. HERMAN VON ZEISSL.

THIS famous teacher, a contemporary and fellow-worker with Skoda, Rokitansky, and Hebra, died in Vienna on September 23d. His reputation as a syphilographer attracted vast numbers of students of all nations to the great hospital in Vienna, and his text-book on the subject enjoyed an exceptionally large circulation. He was born in Moravia in 1817, and studied medicine at Vienna, where he was subsequently offered by Hebra a ward for special investigations of syphilis. In 1850 he was appointed "Privat-Docent," his inaugural address being entitled A Compendium of the Pathology and Therapeutics of Syphilis and Venereal Diseases. This passed through two editions in the course of six weeks. In 1860 he received the Extraordinary Professorship, and in 1864 he published his chief work, A Manual of Constitutional Syphilis, which brought him considerable scientific reputation as the founder of the German dualistic school. In 1869 he was named director of the second ward for syphilis which had then recently been formed in the General Hospital. He filled this office up to a year ago, when he resigned it on account of bad health.

SUFFOLK DISTRICT MEDICAL SOCIETY. *Surgical Section.* — There will be a meeting of the Section at 19 Boylston Place on Wednesday evening, November 5th, at 7.45 o'clock. Communication: Dr. E. H. Bradford, A Case of Subtrochanteric Osteotomy.

S. J. MIXTER, *Secretary.*

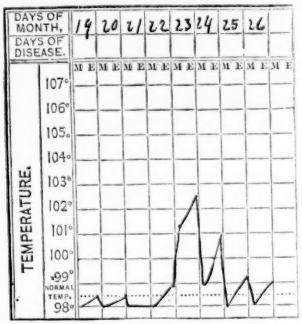
CASES OF ARSENICAL DERMATITIS.[1]

BY JAMES C. WHITE, M. D.,
Professor of Dermatology in Harvard University.

CONCERNING the possible effects of arsenic upon the skin we have a great number of recorded observations, from which it appears that nearly every form of eruption which it is capable of exhibiting in its most varied forms of disease has occurred after the administration of arsenic, and has been attributed to it: macular and erythematous efflorescences, papules, vesicles, and pustules, wheals, furuncles, and ulcers, scales, petechiæ, and pigment deposits. These have presented themselves as local manifestations of cutaneous disturbance, or universally distributed, or have simulated in their arrangement and course distinct forms of dermatoses, as the exanthemata, erythema, erysipelas, herpes, zoster, eczema, pityriasis, psoriasis, etc. Such are the phenomena which, it is claimed, have followed the internal administration of arsenic. Its action upon the cutaneous tissues may, however, be regarded as possibly always a purely local one, inasmuch as it is excreted in part by the glandular structures of the integument.

As to the effects produced by it when brought in contact with the skin in any form from without we have less positive information. Applied purposely as a caustic we know that it causes, in combination with other substances, a rapid destruction of the cutaneous tissues, or that, on the other hand, its action by dilution may be limited to that of a simple depilatory. As employed by workmen in the numerous arts in which it is used, its effects upon the skin are of all degrees of intensity from a fugitive erythema to deep-seated gangrene, and varying in extent of distribution from the limited ulceration about the nails of the taxidermist to widespread forms of dermatitis of all grades. It is my purpose in this paper to present brief notes of three cases of dermatitis, the first two of which were undoubtedly the result of direct contact with green arsenical paper, while in the third case the ætiology is so much a matter of doubt that it furnishes the reason for offering this communication to your criticism.

CASE I. A few years ago a medical student consulted me about his hands. The palmar surfaces were universally occupied by vesicles buried deeply beneath the thick horny layer, as closely approximated as possible without becoming confluent, and varying in size from a large pin's head to a medium-sized pea. They presented with their semi-translucent coverings that peculiar boiled-sago-like appearance considered to be characteristic of the so-called dysidrosis, of which pseudo-dermatosis it might have been taken as a good example. The pressure of the imprisoned fluid produced but a slight bulging of the cuticle overlying the individual efflorescences, but towards the lateral surfaces of the fingers the lesions became more prominent, and in the more yielding epidermis between them well-developed, elevated vesicles. There was considerable general thickening of the integument with much burning and itching. All these manifestations of an acute dermatitis reached their height of development in three or four days, and subsided in the course of the following week, leaving a somewhat prolonged desquamation of the palms, corresponding to the depressed roofs of the vesicles in their stage of involution, none of which were able to discharge their fluid contents. An investigation of the possible exciting causes of the trouble showed that the patient had been using, a few evenings before the onset of the inflammation, a pack of playing cards, the backs of which were covered with a large amount of arsenical green, and I had no doubt that the dermatitis was the result of such contact.



CASE II. On the 19th of March, this year, my opinion was asked with regard to a patient applying for admission to the Massachusetts General Hospital, from which he had been discharged "well" twelve days previously, after five weeks' residence on account of "anæmia and general debility." He had been at work for a week, but for two days his mouth had felt sore, and he had noticed red spots upon his hands and fore-arms. When I saw him these parts were swollen, and presented numerous erythematous patches, which in some parts had already passed into papular forms of inflammation. His face was very red and greatly swollen, so that his eyes were nearly closed. The ears were of nearly double their natural thickness, and were discharging serum. The œdema and redness extended downwards upon the neck as far as it was exposed to view only. There was also serous oozing and crust formation upon the chin.

It was evidently a case of severe artificial dermatitis, the exciting cause of which was not learned at that time. The ill-defined limits of the inflammation, the want of tenderness on pressure, and the slight constitutional disturbance showed that it was not erysipelas. On the following day, the 20th, the face presented a more general incrustation, and there was free oozing of serum from its surface. The eyes could be opened partially. On the 21st the skin of the face and neck remained as before, but the backs of the hands and fore-arms were covered with serous and sero-purulent vesicles. On the 22d the face was still more crusted, and the hair was falling in great quantity from the whole scalp. On the 23d the vesicles upon the hands and fore-arms had increased greatly in number and size, and by confluence some groups had been converted into large, prominent bullæ. There was some oozing from these parts, and crusts were beginning to form upon them. In the evening the patient's condition had become so much aggravated that I was sent for. The face was so swollen that it seemed ready to burst, and, indeed, was discharging serum profusely from numerous points. The eyes were entirely closed. The hands and arms were of enormous size, and were also dripping freely. There had been a great rise in body temperature through the day, and, as shown by the chart on next page, it was at my visit 102.5° F. The pulse was 100. The patient appeared to be in a very dull mental condition, and made but little complaint. On the following morning, the 24th, there was a free general sero-purulent exudation from the face, and the temperature rose again in the evening, but only to 101° F. From this time the inflammation of the skin subsided slowly. On the 28th the eyes could be opened, and the face was nearly free from crusts. On April 7th the patient was discharged well, although the skin of the parts affected was still reddened and desquamating.

It was learned during his illness that he had been engaged for three days previous to the appearance of the cutaneous symptoms in fastening pieces of white

[1] Read at the meeting of the American Dermatological Association, August 27, 1884.

webbing into sample books, the paper linings of which were covered with green arsenical pigment, as determined by chemical analysis. I have seen one other case of severe dermatitis of hands and arms in a boy

engaged in manufacturing elastic suspenders, but could not learn whether the fabric contained the poison. In this case, the most advanced form of cutaneous inflammation that I have ever seen of such artificial nature, and the only one accompanied by constitutional disturbance of any marked degree under my observation, there can be no doubt that the cause of the dermatitis was the arsenical paper. That other workmen employed in the same occupation were not affected in a similar manner is in accord with the general law of individuality. Another exceptional feature in the case was the stomatitis and loss of hair.

CASE III. In the last week of November I was called to see a lady on account of an affection of the skin which presented to her attending physician some unusual features. She had given birth to her first child seven weeks previously, and had made a good recovery. The disturbance of the skin began to appear one week after rising from her confinement, and five weeks after delivery. It had been in progress, therefore, two weeks when I was consulted. At this time the whole trunk was thickly occupied by slightly elevated patches of a subdued red color, varying in size from a pin's head to a dime, circular or oval in shape, and covered with very thin, firmly adherent scales. Some of the largest and oldest patches had undergone involution at their central portions and had assumed an annular form. Upon the upper arms and thighs and upon the neck there were the same appearances, but less pronounced and abundant than upon the trunk. The subjective symptoms were a slight itching or burning of the skin of the parts thus affected, and there was no constitutional disturbance excepting a mild chilliness, such as accompanies many acute dermatoses of the general surface of similar grade. The appearances strongly resembled those of multiple ringworm of the skin, and at the beginning it was thought by the attendants that the disease might be of that nature. It was also not unlike the earliest manifestations of some rare forms of psoriasis of rapid onset and general distribution, in which the scale formation is exceptionally slight. Several of the patches were scraped, and the epidermal cells thus removed with difficulty were carefully examined for the presence of fungous growth, but none was found. Acetate of potash was prescribed internally, and a cooling wash was directed to be applied to the skin.

From this time the disease extended but little more and gradually faded out of existence. Its period of evolution was three weeks, and of decline nearly as long. At the end of six weeks the skin presented no signs of the disease. The diagnosis made at the first visit was pityriasis maculata et circinata, and this opinion was adhered to during the subsequent observation of the affection; indeed the appearances and course throughout were typical of this uncommon dermatosis. As in other cases which have come under my notice, I was again impressed by the inappropriateness of the name applied to it by the French dermatologists who first recognized and described its individual character, inasmuch as the scales are a very subordinate feature in the appearances at any stage of the efflorescence.

During my early attendance upon the case my attention was called to the condition of the baby, then about two months old. It had been feeding upon a wet nurse, and was plump and of healthy appearance. During the preceding week there had developed a papular eczema upon the cheeks and a slight intertrigo behind the ears and in the folds of the neck. In spite of the treatment advised the disease increased rapidly in extent and severity, the whole face presenting within ten days a papular eruption of vivid redness, confluent and excoriated, while a considerable portion of the scalp was affected to the same degree. Upon the neck the opposing surfaces of the integument within the deep folds were intensely reddened and excoriated at their juncture at the bottom of the furrows. In the folds of the axillæ, in the groins, and in several of the deep folds on the inner surface of the thighs the skin presented the same intense grade of intertrigo. Upon the lower legs there was an ordinary papular eczema.

I continued to treat the child from December 1st to February 6th by such methods as I am accustomed to use in similar forms of cutaneous inflammation, but with very little apparent success. One expects in infantile eczema more or less frequent relapses, and possibly an indefinite extension of the disease under treatment, but relapses imply a preceding improvement. In this case I never seemed to have it under temporary control even, and the intertriginous inflammation, which generally is easily managed, behaved as obstinately as the more advanced grades of the process. After the first two or three weeks the child's digestion became disturbed, and the stools assumed a bright green color and were overfrequent. It ceased to gain in weight also. The wet nurse was changed twice, the second one because she had several attacks of acute indigestion, but with the third, a florid, healthy woman in all respects, no improvement in the child's condition took place.

On February 6th the wall paper upon its room attracted my attention (the baby had at first been brought down-stairs for my inspection), and on analysis it was found to be highly arsenical. It was an old French paper, and the pigments were loosely laid on. The patient was removed to another room, and the nursery was repapered. An immediate change in the child took place. The intestinal discharges became less frequent, and after a few days lost their green color; the intertrigo became at once less red and moist;

and there was a gain in weight during the first week of three quarters of a pound. At the end of the second week another pound had been gained, the diarrhœa had wholly ceased, the intertrigo had disappeared everywhere, and there was only a little dry and scaly eczema left upon the cheeks. All these rapid changes ensued without any alteration in the treatment employed.

On the discovery of the arsenic in large amount upon the walls of the chamber the question naturally presented itself to me: May its presumably constant presence in the air of the room not have been the cause of these extraordinary dermatoses both in mother and child? What were the conditions which would warrant the conclusion of so direct a connection between them?

A young lady with an especially delicate skin lies for four weeks in a chamber the walls of which are heavily covered with an arsenical pigment loosely laid on. One week after leaving it for another apartment there is developed over a large cutaneous surface an inflammatory process of rare occurrence, so rare, in fact, that nothing whatever is known of its ætiological relations. As soon as this chamber is vacated by the mother the infant, who has spent the first month of its life in another apartment, with its wet nurse, is transferred to the arsenical room as its permanent nursery, and in ten days begins to present an inflammatory affection of the skin, one of most common occurrence at its age, but of an unusual type. Later it develops marked intestinal disturbances. Both sets of symptoms persist to an extraordinary degree, in spite of repeated changes of treatment and nurses, until the paper is removed from the walls, when the skin and intestines rapidly return to their natural condition. The first wet nurse did not sleep in the arsenical room. The second one was in the room nearly the whole day and night, and had several attacks of vomiting and diarrhœa. The third wet nurse was in the house but a short time before the discovery of the arsenic was made. She remained well, as did the monthly nurse who had charge of the mother during her confinement and subsequently of the child for two months. The two latter nurses were especially strong women.

These are the facts. Do they furnish evidence for a suspicion that arsenic was a factor in these manifestations of disease in this household, or are they explicable on the theory of mere coincidence? If pityriasis maculata et circinata is a well-defined entity, what possible relation can arsenic have to it as cause? Eczema is one of the most common affections of early infancy; why look for any unusual agency in its production here? Has arsenic been known to produce such effects? As just stated, pityriasis maculata et circinata is a rare disease, and we have no data collected to explain its occurrence. I do not know that its association with arsenic in any way has been hitherto observed. It may be that this case furnishes a clue to the ætiology of others which have been reported, could the circumstances attending them be recalled. It certainly should be remembered in connection with those which shall be observed hereafter. With regard to the eczema in the child, it did present some very unusual peculiarities. Intertrigo in the summer months is very common as the only manifestation or in connection with other phases of eczema, but I have never met with a case in which it was so marked in every possible locality for its existence, or so little influenced by treatment in all. This feature in the winter is still more exceptional. Moreover its very rapid disappearance on the removal from the arsenical chamber was a most significant sequence.

WHAT IS REFRIGERATED BEEF?

BY H. LASSING, M. D.

Articles of food are very complex in their chemical constitution, and are exceedingly prone to return to the simpler and more stable compounds called inorganic. The principal promoters of such decomposition are moisture, oxygen, and certain minute organisms. The art of preserving food in a manner to retain its flavor and natural qualities is chiefly modern, as the ancients only understood rude methods, the principal of which were drying and salting.

Animal food may be preserved by several methods, of which the following are the chief: (1.) By immersion in a solution of common salt, to which a small portion of saltpetre is often added, called brine. This acts by abstracting the juices from the meat, and also by preventing the development of organic germs and lessening the tendency to molecular change. (2.) By packing the meat in salt, whereby the juices are abstracted, then removing it and allowing it to dry, and packing in boxes or barrels. (3.) By rubbing with common salt, and drying in the sun, or in a current of dry air. (4.) By salting and smoking, by which means, in addition to the abstraction of moisture by the salt, pyroligneous acid and creosote act upon the flesh, causing it to contract and harden, and also preventing the development of mould. (5.) By drying in a current of warm air at about 140° F., or in the open air at even a lower temperature, when the air is comparatively free from ferment germs. The latter method has long been practiced, especially for "jerked beef," throughout Spanish America and in the warmer parts of the United States. This dried meat may be reduced to powder, packed in air-tight cans, and preserved for a long time. When mixed with fat it forms the pemmican used in Arctic voyages. Spices and dried berries are sometimes added to it. (6.) By cooking to coagulate the albumen, and then inclosing in air-tight cans with exclusion of air, after the manner of canning fruits. (7.) By cooking and pickling in vinegar, a common method of preserving oysters, lobster, and fish. Cooking and seasoning and covering with melted lard or oil is a common method of preserving small fish, like sardines. (8.) By refrigerating and freezing, a process now extensively practiced in all civilized countries, fresh beef being carried from South America to all parts of the world, and in the United States from the Pacific to the Atlantic coast.

There are several special methods which might be classified under one of these heads. Appert's method, introduced in France about 1810, for which he received a prize of 12,000 francs, and which was afterwards patented in England and improved by Donkin, Hall, and Gamble, consists principally in cooking the meats at a temperature of about 240° F., and sealing in air-tight jars. The process has been improved on by McCall & Co., who add a small quantity of sulphite of soda (twelve grains to every pound of meat) to absorb traces of oxygen which may have been left. Still another improvement is the exhaustion of air from the cans by an air pump, and subsequently the passing through the can of nitrogen gas to remove all oxygen, and

then of a small quantity of sulphurous acid, and after this of nitrogen, after which the can is hermetically sealed. The merit claimed for this process is that the meat may be preserved without cooking. The process of Professor Morgan, of Dublin, consists in forcing into the aorta of the recently slaughtered animal, and thence throughout the capillary and venous system, a strong brine containing a small portion of saltpetre, by which means the blood is forced out of the system at the same time that the meat is salted. It may then be cut into pieces, and dried and smoked or preserved in brine. One objection to this process is that it washes out nutritive material. By Dr. Endemann's process the meat is cut into thin slices, and dried in a current of warm air not exceeding 140° F. It may then be ground into powder, kept in air-tight cans, and used for making soup. Mr. Laujorrois has lately communicated to the French Academy a method of preserving food by the use of fuchsine (aniline red), but this is absolutely dangerous.

After all it was reserved for Yankee ingenuity to discover a method of preserving meat in its natural state, without the addition or use of any preservative agent, and by simply shrewd observation of the requirements of the natural laws governing the slaughtering, dressing, and keeping of beef.

To explain this matter intelligently it is necessary first to consider what are the characteristics of good beef, what should be avoided, and what required in its production.

Good beef, then, should be bright red in appearance, the muscular parts firm and elastic, the fat hard and light yellow or white; it should be free from all substances calculated to expedite putrefaction, such as exuded blood, bruises, or extraneous dirt. To produce such beef it follows that the animal from which it is taken must be in a perfectly healthy condition and of the proper age when slaughtered, and that the process of slaughtering and preparing for market must be conducted in such a way as to obviate anything tending to vary from the conditions just enumerated.

Certain conditions may be enumerated which invariably tend to produce poor, unhealthy, as well as unsavory beef, while others just as surely will result in good, healthy, and appetizing meat. No one can deny that long driving and exhausting railroad journeys in crowded cattle cars, with insufficient food and water, the animals goaded, beaten, and bruised by brutal drivers, frightened by unusual noises, will cause inflammatory, congested condition of the meat, and can never result in good, wholesome beef. Again, the careless handling of the dressed meat, filth and dirt allowed to accumulate about the meat in the slaughter-house, insufficient emptying of the blood from the carcass, all injure the quality of the beef.

The blood in its normal condition almost invariably contains noxious elements. From the very nature of the double office of the circulatory system this must be so, for while, on the one hand, the blood serves to renew the various parts of the system after their ordinary wear and tear, on the other it has to carry off the natural waste of the tissues. This waste or refuse is ultimately eliminated by means of the kidneys, the sudiparous glands, etc., and then appears in its avowed character of excrementitious matter; but it must always be, to a certain extent, present in the blood, and in the event of any derangement of the action of the kidneys accumulates in considerable and highly poisonous qualities. It must, therefore, be evident that the blood is always an undesirable article of food, especially as it is impossible when an animal is slaughtered to separate the arterial from the venous blood, which would be the only means of overcoming the difficulty. "We contend," says one writer, "that to use the blood as food approximates very closely to drinking urine, and is not merely loathsome, but, *pro tanto*, unsafe. That, like liquid and solid excrement, it is valuable for plant food, and that it serves as pabulum for certain classes of animals, is no proof that it is fit for human consumption."

The old Jewish rabbins well knew the importance of this, some 1700 years ago, when they recommended that in slaughtering animals, in addition to severing the trachea and œsophagus, the blood should be poured out from the vessels of the neck, and this at a time when it was believed that arteries contained only air.

And yet another consideration, which is that beef should be long enough killed before it is cooked to have allowed of complete relaxation of the muscular contraction of the fibre without permitting even the slightest decomposition to take place. We must not for a moment lose sight of the fact that any process of decomposition may be arrested by antiseptics, yet can never be undone, or, in other words, the destructive work can never be so remedied as if it had not taken place.

It is clear, then, that healthy animals of a proper age, well rested, fed, and watered, killed in such a manner as to produce the least fright and congestion, dressed in the cleanest possible manner, completely deprived of the excessive blood and animal heat, and so kept as to prevent even the slightest decomposition, will furnish the best, most wholesome, and appetizing beef.

The last consideration is the availability of such good beef to the largest number of people. The nearer to the point of production and the more direct a product is bought from the producer the cheaper it must be.

Having thus spoken of the characteristic requisites and cost of wholesome, well-tasting beef, we will now briefly consider if such can be so found within our reach.

In Chicago, one thousand miles nearer the vast cattle-producing pastures of the Far West, are the largest stock yards in the world. Connected with the entire Union by the most extensive system of railways centering here, cattle are brought here from all directions, but more largely from the vast ranches of Montana, Colorado, Nebraska, and Texas, and after being fully rested, fed, and watered, are picked out and bought by a vast army of buyers for local use as well as for reshipment. The principal grades of cattle here represented may be divided, for our purpose, into home-raised and range cattle, and it may be stated that the quality of these latter has been vastly improved during the last few years, not only by more careful breeding, but principally from the fact that so many railroads are now operated through the country that it no longer pays to drive these range cattle on foot save for the shortest distances to the nearest railway station.

The cattle, having thus been carefully selected and purchased, are driven to the cattle-pens of the different slaughter and packing houses which surround the stock yards and form a very large suburb of Chicago.

To give a correct idea of what seems the best method

of slaughtering and dressing animals for the supply of wholesome, good beef for the Eastern markets we will now enter one of these establishments, and follow a steer from the pen to the market in Boston, New York, Liverpool, or London.

One of the largest of these beef-dressing places is located on the edge of the stock yards. These firms are known as Chicago beef dressers. It may be added here that beef dressing simply means the preparation of beef after killing by cleansing it of all uneatable débris and offal, and not, as some intelligent people even have imagined, the application to the meat of any preservative mixture or wash.

The bullock to be killed is driven from the inclosure wherein he is confined to a separate pen, and thence into a narrow stall, where he is alone by himself. Here he is stunned by one or two blows upon the head, which has a double object, — one to disable him, but the more important object is to drive all the blood possible to the brain and forward parts. After this a chain is fastened to him, and through a sliding door he is hauled upon what is called the bed of the slaughter-house. Overhead, throughout the entire buildings, are a system of iron tracks, intersecting and connected by switches, to which are attached sheaves and blocks with hooks, and these, being connected with powerful steam machinery, may be run in any direction. After the steer is thus placed upon the bed his fore feet are so placed as to open as wide as possible the opening which is to be made in his arteries, and thus make sure of the perfect and entire exit of blood. He is again knocked in the forehead until his muscles relax, when a man opens with a sharp knife one of the largest arteries in the body at the lower throat; his head is then entirely severed from the body, and by means of a chain on the hind legs he is hoisted up clear of the floor, and he is shoved into another place to make room for a fresh victim; he is again lowered on the floor, where he is placed on his back, his feet taken off, the skin taken off the belly and sides, the breast and crotch sawed open, and the caul taken off. This caul surrounding the stomach contains the purest fat in the steer, and is washed and cleansed to be converted into the finest and most valuable suet oil. At this stage the examination of the lungs is made, and if any evidence of disease is found the carcass is prepared for other uses than refrigerating, as it has already been shown that such meat will not keep. Thus in the self-interest of these Chicago beef dressers lies the greatest safety of the consumers of this kind of beef. The carcass is then wiped all over, washed free from all blood stains and other impurities; he is then hooked and hoisted up part way, the tail is cut out, furnishing ample material for the celebrated ox-tail soup, the rump is skinned, and, after being hoisted clear of the floor, two men beat down the fell on the hind legs, another takes the hide off the back, the entrails are removed, and the animal is sawn down the spine from the tail, the back is thoroughly washed off and wiped, and split down the middle; he is then hoisted further, and run on a track to more throughly drain out the blood; the hide is entirely cut off from fore legs, neck, the last attachment, and this is done in such a neat, careful way, with clean knives and hands, that the hides from this establishment bring an extra price in the market. The neck is split, and the carcass is trimmed, carefully cutting off all ragged pieces of fat or meat, all blood stains, or bruises. It is again thoroughly washed in two waters and wiped dry, when it is allowed to hang at the back of the beds near the cooler, where, after being allowed to thoroughly drip some fifteen minutes or more, it is again wiped and trimmed, and shoved in the cooler to be entirely deprived of its remaining animal heat. It will thus be seen that the carcass is not only kept very clean, thoroughly emptied of blood, being about one hour or more in transit from the pen to the cooler, but none of the meat is ever under any circumstances allowed to touch the floor. The number of men actually handling the animal from the pen to the cooler is forty-two. In addition to these there are large numbers carrying away offal, washing floors and posts, wiping the hooks and implements, so that at the close of each day's killing there is not any filthy débris or even blood left on the floor. While it is unavoidable for those who do the bloodiest work to keep from soiling their hands and clothing, they are, by the strictest discipline compelled constantly to wash their bodies, and the clothing is changed and washed at every resting spell. All débris is instantly removed and worked up to some useful purpose, so that there can be nothing remaining to cause any foul smell or decomposition; and in the various buildings on the grounds, though every process of manufacture of the débris is carried on, no smell of an objectionable nature is perceptible, and cleanliness is carried to such an extent that a lady with kid gloves could fearlessly handle the wood-work of the coolers and the meat therein contained without soil or stain. The floors of these coolers are covered with clean, dry sawdust, which is changed every other day. These coolers or refrigerators are very simple in construction, with hollow walls, having an ice chamber overhead, the cold air from which is conducted downward, and thus is kept up a constant circulation of pure air at an even temperature of about 40° F. These refrigerators have ample room to hold about 7000 cattle. The cars in which this beef is transported are built on a similar principle, and will each contain from twenty-five to thirty-four cattle. The meat is usually kept forty-three hours before shipment, by which time all animal heat is surely expelled from the meat. It is from three to four days on the way to New York, Boston, Philadelphia, or Baltimore, and on the way the ice is resupplied four times; thus beef sent from this place is at least seven days old when it reaches the New York market. In the winter time the same temperature is maintained, but the ice needs only to be replenished twice.

Beef which has been thus refrigerated will keep out of the refrigerators perfectly sweet and wholesome two days, even in the hottest weather. It is unnecessary to state that ordinary beef not so well cleansed, and not having the animal heat so thoroughly removed, will not keep nearly so long.

By actual experiment made this past summer, with the thermometer varying from 56° F. to 94° F., with two pieces of rib-roast bought in the open market, one being Chicago dressed, the other New York meat fresh killed, but both being from similar cattle as regards quality and weight, the New York killed beef decomposed the third day, while the Chicago beef was perfectly fresh and sweet on the twenty-second day, and was then cooked and eaten. Both were exposed together in the open air away from any ice box.

This concern uses about thirty-three car loads of fresh ice per day. As each car averages fourteen tons, this makes about 500 tons of ice per day.

Ice is very cheap in Chicago, so much so that it does

not even pay to manufacture artificial ice, much less to use any chemical or other artificial means of cooling.

One notable fact connected with this process of slaughtering cattle is that the hearts of animals so killed are always empty of blood, whereas those killed by other processes are generally full. Beef thus prepared is sent by rail to the coast, shipped in similar refrigerators on steamers to Liverpool and London, where it is taken out of the coolers, carted and sent by ordinary rail car to Smithfield and other markets in England, and has always been in good condition and superior to English beef. In one instance meat was thus kept forty-three days on a disabled steamer, and yet was in fair condition on arrival in England.

There has been considerable prejudice created against this so-called Chicago dressed beef by ignorant and malignant misrepresentation, sometimes willfully confounding inferior canned beef, which, because it is also packed in Chicago, has been called "Chicago beef," and again, the writer has frequently seen butchers selling Chicago dressed beef as home dressed beef, while they were vigorously declaiming against this Chicago stuff, and pointing out inferior home beef as being Chicago meat. It has got to be quite customary now with careless reporters whenever, justly or unjustly, meat has to be spoken of as the cause of sickness, glibly to describe it as Chicago beef, thus creating an unfounded prejudice against what is really a wholesome, palatable, and cheap article of diet. Many districts of country which have heretofore suffered for the want of tender, toothsome beef are now well supplied from this source. (About four thousand head of cattle are daily slaughtered in these establishments.)

Some of the prejudice against this beef has been created by the ignorance of the so-called leaders of working men, who led them to believe that by using Chicago meat they were injuring their fellow workmen along the various railroads between Chicago and the Atlantic board, as well as those in the Eastern slaughter-houses. The fallacy of this belief is too evident to require argument.

RAPID COCAINIZATION.

BY HENRY W. BRADFORD, M. D.,
Assistant Surgeon Massachusetts Charitable Eye and Ear Infirmary, Boston.
REPORTED BY WM. DUDLEY HALL, M. D.,
Second Ophthalmic and Aural Interne.

THE anæsthesia of the cornea and conjunctiva produced by the instillation of solutions of cocaine of varying strengths into the lower palpebral sac will undoubtedly be of value in ocular surgery and therapeutics, but to what extent it will replace the anæsthesia of ether remains for a longer use of the alkaloid to determine. The results thus far are very gratifying, and it is to be hoped that there will be no cause for disappointment on the part of the gentlemen who favor its introduction. Cocaine, an alkaloid obtained from the Erythroxylon coca, has been known since 1855, but its application to diseases and injuries of the eye is due to the investigations of a brilliant young German physician, Dr. Koller, of the Vienna General Hospital.

The following are cases occurring in the service of Dr. Henry W. Bradford at the Massachusetts Charitable Eye and Ear Infirmary, in which he has used cocaine from T. Metcalf & Co. for local anæsthesia.

CASE I. Male, aged twenty-five. Incised wound of the ciliary region with prolapse of the iris; right eye. Cocaine, two per cent. solution, the alkaloid having been rendered soluble by the addition of dilute hydrochloric acid. First instillation, one drop; end of third minute, cornea and conjunctiva somewhat anæsthetic, the sensibility being tested with the finger, a quill tooth-pick, blunt probes, and twisted linen cloth; end of fourth minute, one drop; end of sixth minute, cornea entirely insensible to pain, the patient being unable to indicate the precise moment of contact; end of ninth minute, third drop; twelfth minute, operation; prolapsed portion of iris seized with forceps and snipped with scissors, the patient, according to his own statement, not feeling the slightest pain.

CASE II. Male, aged fifty-five. Traumatic ulcer of cornea with hypopion; right eye. Cocaine, two per cent. solution. Both corneæ found to possess the usual amount of sensitiveness when the tests enumerated under Case I. were applied. First instillation, one drop; end of second minute, anæsthesia commencing; end of fourth minute, one drop; end of ninth minute, complete anæsthesia of cornea; conjunctiva incomplete but considerable; twelfth minute, operation; paracentesis of the cornea with a Graefe knife. Upon the introduction of the iris-forceps to dilate the opening into the anterior chamber slight pain was complained of which was not experienced after placing a drop along the line of the incision. The usual pain due to evacuation of the aqueous was not noticed.

CASE III. Male, aged forty-three. Iridectomy for lamellar cataract; left eye. Cocaine, eight per cent. solution. First instillation, one drop; end of first minute, one drop; end of second minute, one drop; no pain upon applying the usual tests; end of fourth minute, patient did not know when the finger of the operator touched the cornea unless considerable pressure was made; end of fifth minute, stop speculum was inserted, and the ordinary operation of iridectomy performed without the patient being conscious of any pain. The hæmorrhage into the anterior chamber was hardly perceptible. This patient was considerably terrified at the prospect of an operation without ether, but appeared very much surprised that it had been completed so quickly, not realizing that anything had been done beyond making an examination.

CASE IV. Male, aged sixty. Needle operation for secondary cataract; left eye. Cocaine, eight per cent. solution. First instillation, one drop; end of first minute, one drop; end of second minute, cornea anæsthetic to the before-mentioned tests; end of fourth minute, operation; cornea perforated by the needles, and the capsule ruptured. The patient, after the operation was completed, said that the discomfort he experienced was no greater than if some one had gently pulled a fold of skin on the back of his hand, and was surprised that an operation had been performed.

CASE V. Female, aged forty. Division of the internal rectus muscle for strabismus; right eye. Cocaine, eight per cent. solution. First instillation, one drop; end of first minute, one drop; end of second minute, cornea and conjunctiva anæsthetic to the usual tests; end of fourth minute, operation; stop speculum introduced; conjunctiva seized and divided. When the hook was placed under the tendon the patient resisted, and complained of pain. The hook was immediately

removed, and a drop was placed near the muscle, after which the tendon was again drawn forward, and the muscle divided without much complaint. The resistance and complaint of the patient from her description of the sensations she had experienced during the operation seemed to be induced by the unaccustomed sensation caused by the speculum stretching the lids, and the traction on the muscle by the hook rather than by the acute pain usually felt by those who submit without an anæsthetic.

Case VI. Male, aged thirty-four. Division of internal rectus muscle; left eye. Cocaine, eight per cent. solution. First instillation, one drop; end of first minute, one drop; end of second minute, conjunctiva seized with forceps, cut, and dissected up and one drop placed near the site of the muscle, which was then divided. The patient said the operation was in no wise painful; the stop speculum was used.

Case VII. Female, aged forty-seven. Modified Graefe operation for cataract; right eye; cataract hypermature, duration seven years, projection and perception normal. Cocaine eight per cent. solution, one drop instilled; at end of first minute, one drop; end of second minute, one drop, cornea anæsthetic to usual tests; end of third minute, the speculum introduced without the slightest resistance on the part of the patient, care, however, being taken not to stretch the canthi; at three and a half minutes after the first instillation the conjunctiva was seized and the cut made; at the end of fourth minute, one drop was placed upon the incision, and half a minute later the iris was seized, drawn out, and divided, the patient complaining of only a slight twinge of pain; the cystotome was used at the end of the fifth and the expulsion was completed by the end of the sixth minute, without loss of vitreous; rubbing on the cornea with the curette for the expression of the cortical substance was not felt; the speculum was removed before the end of the seventh minute. There was but little cortical, the nucleus being very large and firm; the delivery of the lens was delayed somewhat, owing to a wax-like rigidity of the surrounding tissues. The hæmorrhage from the iridectomy was very slight and transient, being in marked contrast to an iridectomy under ether. On examination with the oblique light a thickened and opaque capsule was seen. The patient wished to take ether, but was persuaded to submit to cocaine anæsthesia, and like the others expressed surprise at the absence of pain which marked the various steps of the operation.

Case VIII. Male, aged twenty-three. Foreign body, cornea right eye. Cocaine, eight per cent. solution; three instillations and removal before the end of the third minute; no pain, though considerable force was used to dislodge the piece.

Case IX. Male, aged thirty-nine. Transplantation of pterygium; right eye. Cocaine, eight per cent. solution; one drop instilled; at end of first minute cornea anæsthetic, but patient flinched when conjunctiva was seized with forceps; second drop was instilled, and the operation completed during the third minute without pain.

Case X. Male, aged thirty. Foreign body in cornea of left eye. Cocaine, eight per cent. solution; one drop instilled; removal during the second minute without pain.

Case XI. Male, aged thirty-three. Foreign body in cornea of right eye. Cocaine, eight per cent. solution; one drop instilled, and removal effected during the third minute without pain. The time of operating in this case, as in several others, was delayed somewhat in order to give those who were present at the clinic an opportunity to test the completeness of the anæsthesia, which in foreign body cases is sufficient to permit the removal during the second minute, even though only one instillation has been made.

There have been thus far in this line of cases no bad results noticed; the patient mentioned in Case I., and who was operated upon October 25th, at nine P.M., passed a comfortable night, and his eye is none the worse for this anæsthetic. The patient mentioned under Case II. who underwent operation the same evening had some pain during the night, but the pus has not reappeared in the anterior chamber; Cases III. and IV. are presumably in as good a condition as they would have been if ether had been used; Cases V. and VI. were seen two days after the operation; there was no chemosis, and subconjunctival extravasation was absent; the wound had healed kindly, the only signs of operative interference being perhaps slight displacement of the edges of the incision, and a moderate injection of the blood-vessels.

Dr. Bradford's experience with the alkaloid, when placed in his own eye in the form of an eight per cent. solution, was as follows: First instillation of one drop; at end of the first minute considerable anæsthesia of the cornea; second instillation of one drop; at end of second minute complete anæsthesia of the cornea, and at end of fourth minute conjunctiva anæsthetic; end of seventh minute slight diminution of anæsthesia of the cornea; end of eleventh minute anæsthesia of cornea and conjunctiva nearly gone; end of fifteenth minute anæsthesia totally abolished, and mydriasis commencing; there was no change in the accommodation noticed from this application.

On another occasion he instilled one drop of an eight per cent. solution at intervals of one minute, till eight drops had been used; end of first minute beginning anæsthesia of the cornea; end of second minute anæsthesia of cornea and conjunctiva; sensation of pain and contact with any of the objects used in testing abolished; a sense of pressure if considerable force was applied still noticed; up to the end of the tenth minute the sensation of pressure demanded a constant increase in force in order to be recognized; at this point the pressure sense was abolished; the medium for transmitting the force was a finger or a pen-holder; this state continued till the end of the sixteenth minute, when the pupil commenced to dilate, and there was a feeling of dryness about the eye. Anæsthesia of the conjunctiva commenced to pass away at the end of the twenty-first minute, and sensibility returned to the cornea with the thirty-third minute. The mydriasis was about two thirds and lasted over five hours. Accommodation was affected to the extent of + 1.5 D. On this as on other occasions the cornea was affected first and recovered its sensibility last. The pressure, if considerable, caused a peculiar feeling of nausea.

The motive which impelled Dr. Bradford to have these cases collected, and to prepare this paper, was the hope that there might be a method of rapid cocainization, provided a sufficiently strong solution was used and the intervals between the successive instillations sufficiently short. By the experiments upon his own eyes he found that he could obtain a complete anæsthesia of his cornea by the end of the second minute

when tested by the methods enumerated under Case I. The conjunctiva of the globe offered a greater resistance than the cornea, not becoming anæsthetic till the end of the fourth minute. By referring to Cases III.–XI. inclusive, it will be noticed that the instillations are at intervals of one minute, with almost immediate anæsthesia as a result; the reason for selecting this interval was because in his own eye there was considerable anæsthesia by the end of a minute, showing that absorption was rapid, and by continuing the instillations frequently he hoped to increase the existing anæsthesia of the first drop by each additional instillation, thus reaching the point of saturation sooner. The time for operating was when the cornea and conjunctiva lost their sensibility, excepting in certain instances, when the operation was delayed in order to give the gentlemen who were present an opportunity to examine the condition of the eye.

Case III. Iridectomy, performed during the sixth minute.

Case IV. Secondary cataract, operation during fifth minute.

Case V. Strabismus, operation during fifth and sixth minutes.

Case VI. Strabismus, operation during third minute.

Case VII. Cataract, operation during fourth, fifth, and sixth minutes.

Case VIII. Foreign body removed during third minute.

Case IX. Pterygium, operation during third minute.

Case X. Foreign body removed during second minute.

Case XI. Foreign body removed during third minute.

From the foregoing it will be seen that it is possible to perform these operations within seven minutes from the time the first instillation is made, which is a matter of considerable importance at a large clinic, where time is of value, and this celerity contrasts favorably with the delays incident upon etherization, and it is of not less importance that we have at our command an anæsthetic which permits of the utilization of artificial light without danger to the patient, the electric light being inconvenient outside of an office or hospital.

The sort of cases for which cocaine seems to be especially adapted are operations about the cornea or conjunctiva; in the removal of foreign bodies imbedded in the cornea it will probably have its widest application. Bowman's operation can be performed without pain, and the passage of probes probably facilitated by the injection of a solution into the canal or by lubricating them with the alkaloid incorporated with a proper vehicle. For a thorough examination when blepharospasm is present it is certainly of practical value.

The operations for pterygium and strabismus can be performed with ease, but a local application beneath the conjunctiva is advisable in the latter. In the operation for cataract and iridectomy it is preferable to ether, because the hyperæmic condition which exists during ordinary etherization is avoided, and there is no danger of straining, coughing, and vomiting on the part of the patient, which so tends to increase the vascularity of the part, and to favor free hæmorrhage into the anterior chamber. The mydriasis, unaccompanied by any prolonged disturbance of the accommodation, is of course an advantage over that produced by the present mydriatics when used to aid in diagnosis with ophthalmoscope. In the treatment of iritis it will probably not supersede atropine, though in combination it would perhaps be of value in relieving the nocturnal pain. In cases requiring long operative interference cocaine has a practical application from the fact that Dr. Bradford found it possible to maintain a continued anæsthesia for several hours.

OCULAR ANÆSTHESIA PRODUCED BY COCAINE.

BY CHARLES H. WILLIAMS, M. D.

In the *Medical Record* of October 11th, Dr. H. D. Noyes published a letter calling attention to the discovery of Dr. Koller, that cocaine when applied to the conjunctiva caused a local anæsthesia. Since then several cases have been published in which it has been used, and the following cases will serve as additional evidence of the great advantages which may be expected to result from its use in ophthalmic surgery.

A four per cent. aqueous solution of cocaine was obtained from Messrs. Theodore Metcalf & Co., and its effect was first tried upon my own eye with the following result: In three minutes after the instillation of one drop of this solution into the conjunctival sac of the right eye a perceptible diminution of the sensitiveness of the cornea was noticed; in five minutes this was more marked; the cornea when touched with the point of a bit of note paper felt the touch, but there was no acute pain or involuntary flinching. This effect lasted about ten minutes, when the sensitiveness of the cornea slowly returned, and was completely re-established in about twenty minutes from the time of the application. About twenty minutes after the instillation of the cocaine the pupil was seen to enlarge, and this slowly increased until it was about one and a half times the diameter of the unaffected pupil. This change continued for some three quarters of an hour, when it began to subside, and after an hour and a half only a trace of enlargement was noticeable. The range of accommodation remained nearly the same as before, but the near point was removed slightly from the affected eye. There was no change in the vision for far or near, nor any difference in the tension of the globe.

In the second experiment a drop of the same four per cent. aqueous solution was dropped into the conjunctival sac of the left eye, and this was repeated after an interval of one minute. Here, as in the other case, anæsthesia of the cornea began to be noticed in three minutes, and became quite marked in five, so that the conjunctiva could be seized with fixation forceps or the cornea rubbed with the point of note paper without producing pain, although here, as before, the touch was felt. In this case the anæsthesia of the cornea lasted nearly twenty minutes, though gradually diminishing during the last five. Enlargement of the pupil came on in about seventeen minutes, and lasted for about an hour. At one time the shape of the pupil was slightly irregular, but its reaction to light was always good. In this eye the same receding of the near point was noticed during the dilatation of the pupil, but the vision, tension, and range of accommodation remained nearly as in the other eye. Encouraged by these results I used the same solution in a

case of extraction of cataract by the modified Graefe operation.

CASE I. Mrs. C., sixty-four years old, rather stout and nervous, had double cataract. Three applications of a four per cent. solution of cocaine were made to the conjunctiva of the right eye at intervals of five minutes, and fifteen minutes after the first instillation the operation was performed. The ocular conjunctiva was seized by the fixation forceps, and the patient not being warned the corneal cut was made without her knowing it. The operation was completed without difficulty, and the patient was surprised to find that everything was finished.

CASE II. Mr. E., traumatic cataract, with piece of metal lodged in the lens. August 8th, while using a hammer and chisel, a piece of metal flew into the right eye. Examination showed a penetrating wound of the cornea about one millimetre long at the upper and inner side of the pupil; also a slight wound of the capsule of the lens nearly in the centre, and imbedded in the lens at the outer and lower side of the pupil was a small, glistening fragment of metal. The fundus was normal. He was kept under observation for some days, but no opacity of the lens appearing, nor any irritability of the eye, he was allowed to go back to work. September 22d, nearly a month and a half after the original injury, he was again seen. The corneal and capsular scars remained unchanged; there was no opacity visible in the lens, and the bright metal could still be seen imbedded in the lenticular substance. Vision normal in the left eye and nearly normal in the injured eye. October 29th he presented himself suffering with much pain in the injured eye; there was a considerable circumcorneal injection; the lens was entirely opaque and swollen; the iris was pushed forward, and the pupil somewhat enlarged; given atropine one per cent. October 30th two drops of a four per cent. solution of cocaine were dropped into the conjunctival sac, and this was repeated in five minutes. After an interval of five minutes the foreign body and lens were removed by suction, without causing any discomfort to the patient. A spring speculum being placed between the lids, an opening was made through the upper part of the cornea with a bent, broad needle, large enough to admit easily a hollow suction tube measuring three millimetres across. Gentle suction being now made by the mouth, by means of a rubber tube and mouthpiece attached to the instrument, a portion of the lens was removed. It was then found that the tube had become clogged, and on withdrawing it the piece of steel, shaped like an arrow head, about one millimetre across, was found plugging the opening in the metal suction tube. This being removed, the rest of the lens was extracted by suction, and before the bandage was applied the patient could count fingers at one meter. There was no complaint of pain during the operation, nor any involuntary motion of the eye.

CASE III. Stricture of the lower part of the lachrymal canal. On probing, after two applications of a four per cent. solution of cocaine, there was less pain than before without it, but even with the cocaine the pain was appreciable.

CASE IV. Granular conjunctivitis with pannus. One application of the same solution of cocaine was made to the conjunctiva, and ten minutes later, when the lids were touched with the crayon of sulphate of copper, very little pain was felt, although in the other eye the pain was quite severe.

A DISCUSSION OF SOME OF THE QUESTIONS OF MEDICAL EDUCATION AND MEDICAL ETHICS.[1]

BY HENRY LEFFMANN, M. D., D. D. S.

FROM the valuable volume on medical education published by the State Board of Health of Illinois we learn that the United States contains 123 medical colleges, of which ninety-one are classed as regular. The Illinois Board has been an active one, has adopted a list of minimum requirements for admission and graduation, and in conjunction with other State Boards has accomplished much for medical reform, as the following figures will show: Prior to its present organization thirty of the regular colleges required an admission examination, now fifty-nine require it, and this number will doubtless be largely increased next year. Ten colleges formerly required three courses of lectures, sixteen now require them. The course of instruction has in many institutions been improved by the addition of chairs of hygiene and medical jurisprudence. A part of these improvements has been brought about by the natural progress of educational methods, and by the desire on the part of teachers to add to the attractions of their institutions, but a portion is also in deference to the demands of the State Boards.

A perusal of the volume referred to, in which the requirements and facilities of the colleges are set forth, shows us how very unequal is the character of the education given in different parts of the country. With some of these institutions the course of study must be a mere pretense.

It has been apparent for many years that active measures must be taken for securing reform in medical education. In considering the topic we must bear in mind the responsible position which the medical man holds in society. He is no longer called upon merely "to give the potions and the motions." Education and legislation, the control of which has for centuries been in the hands of clergymen and lawyers, is becoming largely a medical problem, and the well-informed physician becomes a factor of no mean importance in social progress. At the same time the requirements of a thorough medical education, in the narrowest sense of the term, — that is, a knowledge of disease and its treatment — has become a problem of far greater difficulty than it was a generation ago. A correct and sufficient knowledge of the instruments of precision requires an acquaintance with various accessory sciences. The laryngoscope and ophthalmoscope involve optical principles, the elaborate electrical machinery employed calls for a more than rudimentary acquaintance with mathematics and physics, and the many chemical tests which are required for diagnosis involve a need for some practice in the chemical laboratory. On the other hand, the importance of classical training has been overrated, and in the preliminaries to a medical education it may receive scarcely any attention, but its place is supplied by two of the modern languages in which so much of the important scientific literature is found.

In offering a synopsis of the directions which medical reform should take I may conveniently present the topic under four heads: first, the preliminary examination; second, the course of study; third, the method of graduation; fourth, the ethical relations.

[1] Read before the Philadelphia County Medical Society, September 24, 1884.

The preliminary training presents great difficulties. It is nearly impossible to say what amount of actual information would be the minimum which should qualify a young man or woman to enter the study of medicine, and the opponents of the admission-examination system have urged this as an objection, and have spoken about "natural aptitude" in those comparatively uneducated, "rough diamonds," etc., which are likely to be unjustly excluded on account of technical deficiencies. Yet it must be noted that all colleges and high schools conferring degrees other than those of medicine have always had such conditions of admission, and no one has ever thought the obligation burdensome. I do not think that the requirements for admission to medical schools should include a knowledge of the dead languages, except, possibly, an acquaintance with the regular declensions of Latin nouns — a degree of information which could be acquired in a few hours; the value of the knowledge is only its bearing on correct prescription-writing. I take issue, therefore, with such conditions as those imposed by Harvard College, which requires the translation of easy Latin prose, and also the schedule of the Medical Society of this State, which imposes a knowledge of this tongue. On the other hand, an elementary knowledge of algebra and geometry is essential to a correct understanding of the teachings of chemistry, electro-therapeutics, and ophthalmology, and from practical experience I know that insufficient preparation in these matters has cost many a student a vast amount of labor and study. It is not at all improbable that as the standard rises some of the essentials of anatomy and chemistry will be entered among the preliminary requirements.

I must also object to the following requirements in the Pennsylvania schedule: botany, logic, drawing, Greek, political economy, and algebra, except to simple equations. Botany, as generally studied, is a mere accomplishment, and its practical value in medical science is very small. Political economy is, in my opinion, a department of science in which the danger of a little learning is very serious; it has no elements.

We must by all means regard the preliminary examination as a protection to the pupil. It is said that one of the head masters of Eton would not infrequently say to the scholar about to be thrashed, "Sir, this is the office of a true friendship." Pupils do not take kindly to admission examinations, and it will be more difficult to enforce them in medical colleges because every one has become accustomed to the unrestricted acceptance of students.

An effort will have to be made to secure for this examination an approach to uniformity among the different colleges. It will not amount to much if each institution is allowed to set up the standard for itself, and to determine privately how far each pupil attains it. It is hinted that in some institutions which have made great claims on account of their admission requirements, and the diplomas of which have received special privileges abroad, the examination is a mere form. The attitude which the Medical Society of Pennsylvania holds in reference to this topic is very unsatisfactory. For years it has been adopting resolutions and threatening punishment, but it seems never to get its courage up to the point of insisting on reform. These standing resolutions appear to be remarkable for little else than their hollowness and insincerity.

Opportunities for great improvement are to be found in the course of study. It would be curious to know under what circumstances originated the extraordinary method of medical instruction according to which the student is not to know anything, however easy, if he has heard it once, and to know everything, however difficult, when he has heard it twice. I cannot see that this state of affairs is materially improved by extending the term over three years. It relieves, perhaps, the pressure of study, but it only nominally lengthens the course. It is now generally thought that the science and art of medicine cannot be acquired in two years, and most of the American colleges state in their announcements that the candidate for graduation must have studied three years. The usual plan is, however, to allow these three years to be two courses of lectures, and one year under a preceptor, whose certificate to that effect is generally taken. When it is remembered how easy it is to secure such certificates, and how irregular and uncertain is the instruction often given by preceptors, it will be seen that this preliminary year may be a fiction. If a year outside of college is to be counted at all it should be upon a record dated at the beginning of the year; that is, the pupil should produce evidence of having declared his intention to pursue his studies for a year in a physician's office. I do not think, however, that this matter will require much attention, for the pre-college year will soon be abandoned. Another method by which the study is cut down to short periods and insufficient work is the practice of giving credit at one college for the time spent at another. As a general rule the evidence of the prior study is merely the statement of the pupil and the exhibition of a full set of tickets. Neither of these is sufficient proof of actual attendance, and even if they were there would still be no proof of the student's fitness to proceed with the second course. The proper test of the student's fitness to proceed with his studies is an examination. This is the test that non-medical colleges would apply.

The most radical improvement that I have to suggest is that to which I have already referred in a paper before the Medical Society of Pennsylvania, namely, that the full college course should include a recognition of each specialty, and offer the option of pursuing the study of one or more of them, not as side studies or post-graduate courses under junior teachers, but as part of the requirements of graduation. I have compared this plan to that under which the universities give courses of instruction in mechanical, mining, or civil engineering, the option of one or the other being left to the student. The whole tendency of medical practice is towards specialism, and one of the difficulties of maintaining the ethical standard is the constant struggle of specialists to draw attention of the community at large to their lines of practice. Forbidden to advertise directly, they seek methods that are illegitimate. I think it will be admitted that the best interests of the profession and the public are subserved when the patient is directed to the proper physician with the least inconvenience, delay, or confusion. Those who object to specialism forget that the degree of M. D. is itself a special degree, and limits the service of those who bear it. No one objects to the degree of D. D. S., and no one can deny that the value of dentistry has been vastly improved by the establishment of colleges and the creation of the degree. Why should we not multiply these degrees, and so arrange the college courses that each

might be conferred on those who prepare for it? Doctor of ophthalmology, otology, or dermatology may seem strange to our ears, but they are as reasonable as the titles bachelor of science, of mining, or of music now conferred by the universities. *The Journal of the American Medical Association* has declared it allowable for a physician to put on his card "practice limited to such and such diseases," but I do not think that this view has been generally accepted. The proper method to secure recognition is by degrees, which indicate that studies have been pursued which fit the practitioner for the work undertaken. "John Smith, M. D., D. D. S.," is the legitimate manner of showing that the said person has pursued a course of study in general medicine, and then in a special department. I cannot see why "John Smith, M. D. O." should not indicate the same with regard to ophthalmology. I wish to present the idea that these special degrees should all be in the compass of a regular medical school; the studies for the first year would be the same for every degree, but in the second and third years they should be directed to the end in view. I consider this preferable to forcing all into the same studies and then resorting to post-graduate instruction as a preparation for practice. Instead of a faculty of seven chairs it would be more satisfactory to have fourteen. There is no good reason why the instructors of diseases of the eye, ear, or mind, and nervous system should not stand on an equal footing with the professor of gynæcology or obstetrics, instead of being, as they now are, mere appendages to some chair, or recognized only as subsidiary summer lectureships. That some of these departments cannot be satisfactorily included within the original chairs is because they are, for the most part, developments of late years. Sanitary science, psychiatry, and inebriety have become distinct sciences. The first has acquired so much importance that in some States of the Union a knowledge of it is necessary to the validity of a medical degree.

It is not possible to present here all the details of college instruction, but I think that a few words should be said about the thesis. As a rule, it is of little value. Under the system of preliminary and term examination it will have less value, for it is now looked upon mainly as an index of general proficiency in orthography and grammar. It would be unreasonable to expect students to produce anything of scientific value. There are, however, some exceptions, and it is not unwise to extend direct encouragement to those who seem to possess the means and desire for original work, and to reward the effort in proportion to its merit. I would, therefore, say that no theses should be exacted, except those that are to compete for prizes, and that, after the award is made, all that are deemed worthy of mention should be published.

In this connection I wish to allude to a department of instruction for which there is special need in this country, that is, medical jurisprudence. It is a common opinion that the mere fact of a man being a doctor fits him for expert service, whereas there is very little attention given to the topic in medical schools. The recent suggestion of Dr. Bronadel, made before the French Society of Legal Medicine, seems most admirable. It is that a regular college, or at least a regular course of instruction, should be instituted in medical jurisprudence, the evidence of proficiency being in the conferring of such a title as Doctor of Medical Jurisprudence. Only persons bearing such title would be competent experts, and undoubtedly in such an arrangement some of the objectionable features of expert testimony would disappear.

I think it cannot be denied that a feeling is gaining ground in the community that the right to practice medicine is one that should be more completely under State regulation than at present. The objects to be sought are that all practitioners shall be able, and as nearly as possible equally able, and the latter cannot be attained as long as the graduation is made to depend on the standard set up by individual institutions. The transfer of the work of examination to a State Board, and the conversion of the colleges to centres of instruction only, would solve several of the troublesome problems of college management. The faculties would surely not regret the loss of the labor of either the oral or written examination. It would place competent and efficient teachers on a much higher plane than they now are, while it would go far towards crowding out inefficient ones, for each examination would be a record of the manner in which the candidate was prepared. These State Boards should accept any one who could bring certificates of good moral character, proper age, sufficient preliminary training, three years' study under instructors recognized by the Board. Under the present arrangement a student attending any given college is obliged to take all his instruction from the Faculty thereof. If one or more of the professors are inefficient he must take extra time and spend extra money to get proper preparation. Under the system here advocated he could select his instructors from the dierent faculties accessible to him. Such a weeding process would very soon throw out the weak teachers, and form faculties strong at all points, and this surely would be to the advantage of the profession and its education.

A vital question that arises in reference to State Boards is their relation to the different schools of practice into which the medical profession is unfortunately broken. It is the fear of the homœopathic portion that has in part prevented the establishment of these boards. They are afraid that they will be used for the purpose of preventing any but regulars from getting into practice. They have insisted on, and I believe obtained in most cases, recognition and representation. I desire not to be narrow or bigoted, but I cannot divest myself of the impression that it is thoroughly absurd to suppose that there can be two systems of therapeutics; but, however this may be, the course to be pursued by the State is plain. The majority must rule, and the system which is most comprehensive must be insisted upon. There can be no question that the majority of both learned and unlearned persons in such a community as ours favors what is known as the regular system. On this ground, therefore, a knowledge of that system should be required for practice. Those who desire to pursue any special system might, in addition, be required to pass an examination in the special features of that system.

The adoption of the system of official supervision will be slow, but the profession, especially of the larger commonwealths, has it in its power to anticipate the system in a tolerably satisfactory manner; that is, by means of examinations before committees of the State or County Medical Society, these examinations being in addition to those given by the Faculty. One of the New England colleges already has this plan, and an analogous method has been in use in the College of

Pharmacy of this city, a committee of the Alumni Association giving a set of questions covering the principal branches of study.

The vexed question of medical ethics is not a suitable one for general discussion, but I cannot close this paper without expressing my agreement with the views advanced by Dr. Gihon, at the Cleveland (1883) meeting of the American Medical Association. Times have changed, and medical education has much changed, since the section of the Code was written which proscribes as irregular any one "whose practice is based on an exclusive dogma, to the rejection of the accumulated experience of the profession and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry." Under State Boards, all students would be obliged to pursue these studies, even if the different colleges did not have them of their own accord. I am not disposed to advocate consultation with non-regulars, but I think that the ethical error at the present time is, that while many are excluded who are only nominally at variance with the requirements of the Code, many are admitted who are only nominally in agreement with it. The standard for admission of a physician to professional relations ought to be his moral character and educational attainments. Failing in these, it seems to me he is unfit, though he proclaim ever so loudly his faith in the letter of the law, and sign ever so often a printed promise to abide by it. In the words of Dr. Gihon, "Medical education is the true standard of medical ethics."

I have brought this paper forward with a view of eliciting discussion on all the points, but particularly on those that seem new. To me the fallacies, if any exist, in the arguments are not observable; but those who approach the question from a different point of view may discern them, and I trust any such weak spots will be pointed out. I expect that it will be urged in objection to some of the schemes that they would involve too complicated arrangements, but I think this is most in apprehension, not a reality. I presented views somewhat similar in a paper read before the Medical Society of Pennsylvania, but of course no opportunity was there presented to discuss it. The question of advance in medical education appears to be attracting more attention in the West than in the East, and we may infer that the reforms which the colleges will not of themselves make will be forced upon them by the official requirements. The Illinois State Board of Health has adopted the following as the minimum requirements to constitute a college in good standing, and the Nebraska State Medical Society has adopted them as conditions of eligibility to membership: —

Conditions of Admission. — Credible certificates of good moral character. Diplomas of Literary College or Preliminary Examination in English, Mathematics, and Elementary Physics.

Branches to be Taught. — Anatomy, Physiology, Chemistry, Materia Medica and Therapeutics, Theory and Practice of Medicine, Pathology, Surgery, Obstetrics and Gynæcology, Hygiene, Medical Jurisprudence.

Length of Courses of Lectures. — Two of not less than twenty weeks, and not more than one course in same year.

Attendance. — Regular attendance, absence by sickness only allowed, and not to exceed twenty per cent. of the course. Examinations by quiz twice a week. Final examination to be conducted when practicable by other than professors.

Dissections and Hospital Work. — Two courses of each.

Duration of Study. — Not less than three years.

The college must show that it has a sufficient corps of instructors and facilities for hospital work.

The points presented for discussion to-night are: —

What should be the extent of the preliminary requirements, and how should they be ascertained?

How far should specialization of the course be carried, and would it be feasible to confer special degrees?

Could such a special degree, as Doctor of Medical Jurisprudence, be conferred, and would it be of advantage?

Would the profession and the community be benefited by a State Board of Examiners, who alone should have power to grant licenses?

If a State Board should be established, do the interests of the higher education require that any but regular practitioners should be represented on it?

In case a student transfers himself from one college to another of equal standing, should he be subjected to an examination with a view to determine his fitness to pursue his studies?

Reports of Societies.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

SEPTEMBER 24, 1884. DR. LEFFMANN read a paper on

MEDICAL EDUCATION.[1]

DR. OSCAR H. ALLIS, in opening the discussion by request of the Chair, said: The whole matter of medical education, as it confronts us to-day, is, not what we would desire, but what is the best course to pursue under existing circumstances.

Were I to map out a plan that I should feel would advance the student of medicine most rapidly, and prove of the highest permanent good, I would insist upon a judicious and adequate preliminary course of study.

But viewing matters as they are, such a standard is impractical, and this the lecturer knows too well. I would, then, take the student just as he is, presuming, of course, he has made sufficient advancement in the rudiments of an English education, and at the very outset of his medical education put him with instructors in the practical branches of his course, thus bringing teacher and pupil into daily and hourly contact, rather than have them meet but once, and that at the end of a short two years' course of study.

We all have our ideals. Were I to found a medical college, some such preparatory course would be adopted, and no one would be permitted to attend upon the lectures of the professors until he had mastered the elementary branches, such as anatomy, chemistry, materia medica, and the like, under competent teachers, and with all the advantages of laboratory and class instruction. For my own part I know of nothing more unsatisfactory, more distracting, than for a surgeon to attempt to explain the nature, importance, or difficulties of an operation to a class half of whom have never entered a dissecting room. He must either ignore the freshman or descend to his level, and in either case doing new-comers, the advance pupil, and himself, great injustice.

If I understand the lecturer correctly, he would dispense with the preliminary examination, such as now demanded by the Medical Society of the State of Pennsylvania and in many of the medical colleges throughout the land. With this I cannot agree. I know of no

[1] See page 440 of this number of the JOURNAL.

better time or place to ascertain the fitness of the student for his work than at home and at the outset of his studies. Preliminary examinations are meant to deter only those whose elementary studies have been grossly neglected.

Dr. William Pepper: Mr. President, when I received your special invitation, I determined to be present this evening in order to benefit from the views of others. I will, however, make a few brief remarks upon some of the points touched upon by Dr. Leffmann; and first, as to preliminary examination: I think it is a great thing to have one, and even though it be not adequate nor properly enforced, still the mere statement that there will be an examination deters lazy and badly-prepared students from even applying; and if a mere shadow of one be thus useful, we may imagine how valuable uniform and properly enforced examinations will be. Unfortunately, there are but few colleges which exact them, and it is a question for the profession at large to decide whether all colleges shall or shall not establish this essential requisite of good education.

So long as students are sent to colleges which have no such preliminary examination, and which have a comparatively low standard of requirements, so long will such colleges continue in their course. In regard to the character of the preliminary examinations, I consider a good knowledge of mathematics and of physics, together with the elements of a good English education, of much more consequence than the classics, and I would willingly accept proficiency in modern English as a substitute for the latter.

I do not believe in differentiation of medical studies at an early period. It is true that modern practice leads to more and more specialization, but unless we insist that the specialist shall have the broadest general education his value as a specialist is greatly endangered, and I cannot help feeling that if students were to be encouraged at an early period of their course, as being engaged for fitting themselves for this or that specialty, the tendency to concentrate their attention upon it to the serious neglect of the necessary elementary branches would be insuperable. Equally strenuously must I object to any increase in the number of degrees. Already the variety of degrees bestowed by American colleges is ridiculous, and if we were to enter upon the practice of giving different special degrees for attainments in different specialties no one could foretell the chaos of titles which would result. The truly reliable specialist readily becomes sufficiently distinguished in the esteem and confidence of the community.

I cordially agree with Dr. Leffmann with reference to a State Board of Examiners, but until that becomes possible our final examination should be made more practical. The candidate for graduation should be compelled to show his knowledge in actual diagnosis and the direction of treatment, and it will be easy to invite several disinterested physicians to attend such examinations, which would thus acquire almost the success of those conducted by a State Board. In colleges where a suitable preliminary examination is held, the thesis seems to me to no longer possess much value, and I would suggest substituting for it the preparation in each term of one or more clinical records by every student, which would certainly serve not only as a test of literary qualifications, but as evidence of their close attention to practical teaching. I would further offer prizes of special grade of merit for voluntary theses, based upon original investigations.

With reference to the time of beginning clinical studies: I realize the difficulty of lecturing to an audience a considerable portion of which are still ignorant of the very rudiments. There is, however, a kind of practical instruction which is really clinical, which should begin at the very outset of the student's course, and for which I am happy to say provision has now been made in the University of Pennsylvania. I refer to the demonstration before small sections, with careful training of each individual student in the perception of the normal physical signs. This will afford most valuable training for the first-year students, while it will enable the student in his last year to receive true clinical teaching in the wards, instead of being compelled, as is now too often the case, to spend his last year in elementary practical work, which could be mastered by the veriest tyro.

Dr. Charles K. Mills: I do not agree with the views presented by Dr. Leffmann on the granting of degrees for attainments in specialties, but rather with those of Dr. Pepper. It would be unfortunate to multiply the number of degrees. It is highly important, however, to have instruction and examinations more specialized. As it is now the examinations are only on seven or eight branches. Nothing so stimulates the student as the knowledge that he will be examined on his work. The thing to do, as long as examinations are still held by the colleges, is to specialize them as much as possible. There is no danger of this making specialists, though the giving of the degrees mentioned might have the tendency to check pseudo-specialists. It is well known that the University of Pennsylvania has recently added a fourth year for special instruction to under-graduates and graduates. An examination is held on each branch. Those who took this course last year went before the Examining Board of one of our large hospitals for examination for the position of internes. More than half were successful, though no specialists were on the Board; an excellent showing for the method of instruction and examination pursued in their cases.

Every institution should have at least a full and regular course on medical jurisprudence, but it is a mistake to suppose that a general course of this kind will of itself make medico-legal experts. It will further and more fully equip those who are already medical experts in special departments. The physician of the specialty concerned becomes the true expert in the case under trial, and as these are diverse there cannot be a general professional expert. The question involved may be one of insanity, nerve injury, ophthalmology, poisoning, etc., requiring a physician who has especially devoted himself to a certain line of work for many years.

Dr. J. E. Garretson: I compliment the man who, in this dollar-and-cent age, directs attention to the flaws in American medical education at the expense of his pocket. A full half of the young men that come to Philadelphia to study medicine should be turned face about and sent to a village school. Examinations are against big classes, while little classes are against the exchequer. It is a pity that the medical schools are not endowed; otherwise, it is a pity that American professors are not, like the Germans, able to subsist on lager beer and pretzels. Personally I favor preliminary examinations, or, if this be not democratic, be not

what people call "giving a fair chance," why then let a student, even though he be dull as a clod, be allowed to enter the freshman class, but let him be kept in this class until he helps himself out of and over it. Going to school is synonymous with growing a medical junior. If a freshman fall short of an *m* in inflammation, or if he insist on spelling college with a *d*, it hardly seems unfair that time be allowed him to turn to a dictionary which shall be neither Dunglison's nor Thomas's. Perhaps, when all is said, time, and not examination, is the thing. Two years for the making of a doctor! Is it not farcical? This paper, by the essayist of the evening, should receive every attention; it has the ring of science, and not of silver. If it be not for a good to ourselves, why then for the benefit of the world, let not the doctorate be cheapened. Already the degree is not what it once was. The matter of standing is now in personality, not in a degree. No diploma seems safe in the hands of the democratic American. To-day boys are found full-grown doctors of philosophy.

DR. JOHN B. ROBERTS: Mr. President, I fully recognize the importance of a preliminary examination to the intending student himself, for I believe he had better prepare for the preliminary examination of the succeeding college year than to enter college a year earlier with a deficient knowledge of fundamental educational branches. The argument that a poor student, deficient in education, cannot afford to wait a year before beginning medical studies is specious. Let him work at the plow or desk that year, buy a few second-hand books, devote two hours a day to study, and he will not only be making money, but will, at the year's end, be able to pass a preliminary examination. Thereafter medical studies will be intelligible to him, the final examination more easy, and a higher professional income assured. A year will not be lost, but gained.

While I believe the preliminary examination advantageous to the pupil, and therefore indorse it, I deem it unnecessary if the medical colleges could be compelled to adopt a high-grade final examination. The examination then should be partially written. As the United States Naval and Army Boards need no preliminary examination, so would medical colleges need none. I know that in the Naval Board, and probably in the Army Board also, many candidates, though graduates of noted schools, are rejected because of inefficient general education before they come to the professional examination. A man who cannot write a simple record of his own life, in his mother tongue, is not apt to reach the professional examination before the Examining Boards, composed, as they are, of men whose duty is simply to find out what the candidate knows. This shows the advantage of examining boards whose income does not depend on the number of candidates passed.

My former experience as a quiz master gives me some right to speak of the defective knowledge often found in advanced medical students. I have also read some graduation theses. Perhaps some other members of this Society have enjoyed that high privilege. If any such are present they will remember the circumstance because of the ludicrousness of the high-sounding name "thesis." The Paris theses are printed, and often referred to as sources of medical information. A collection of all the theses presented to the American medical colleges during the last five years would be more entertaining than that book of books, English as She is Spoke, and no Mark Twain's preface would be needed.

Does it not seem strange that the profession of Pennsylvania should take no radical step to elevate medical education, when Illinois, Virginia, and even the youthful Nebraska have struck terror into the heart of the half-educated graduate. The State Board of Health of Illinois will not recognize a diploma as entitling the holder to a certificate for permission to practice in Illinois if the college granting it falls below the minimum schedule. This schedule requires a preliminary examination or equivalent documentary evidence and teaching in hygiene and medical jurisprudence in addition to the ordinary branches. It also demands three full years of professional study, quizzes at least twice a week, and the final examinations to be conducted, when practicable, by examiners other than the professors.[1] How rigidly this standard is enforced I am unable to say, but I know that a graduate of last year in this city, who intended settling in Chicago, showed me a few months ago his papers telling him to appear for examination in hygiene before the Board. What a slur upon Pennsylvania medical teaching! A Philadelphia doctor who graduates with honors cannot practice on the western prairie until he is examined as to his professional knowledge. In other words, he is a good enough physician for old Philadelphia but not for the young West. Humiliating, truly! but not to Illinois.

Virginia has done even better, for she has established a State Board of Medical Examiners, before which every applicant for practice, after January 1, 1885, must pass a satisfactory examination before receiving a license to practice medicine or surgery. Two examiners-at-large are to be elected by the Society, three from each of the ten electoral districts of the State. A fine of $500 is to be imposed upon those who do not comply with the terms of the law.[2]

The Nebraska State Medical Society also is on the alert, and will accept as member no physician who is a graduate of a college falling below the requirements of the Illinois State Board of Health.[3] Those requirements I have already indicated. Philadelphia doctors will scarcely be welcomed in any part of the United States if this epidemic demand for educated physicians extends much farther. As we cannot control the epidemic, had we not better take the quickest possible steps to elevate ourselves to the level of the profession of the prairie and the plain.

New York, or at least the Erie County Society of New York, has endeavored to have a legislative enactment passed, providing for a State Board of Medical Examiners. Soon our graduates may be debarred from practice in New York also. The time has evidently come for conservative Pennsylvania to fall into line and act.

The Medical Society of the State of Pennsylvania has for many years been passing resolutions bearing on this question; but to resolve is not to act. I myself was one of those appointed by the State Society to prepare a schedule for preliminary examination of intending office students. The schedule was adopted

[1] Medical Education and the Regulation of the Practice of Medicine in the United States and Canada. Issued by the Illinois State Board of Health, 1883, p. 4.

by the Society, and the law became operative in some of the counties, but in Philadelphia it has been entirely unheeded up the present time.

The correct remedy for defective education and examination in this State is, as Dr. Leffmann has said, the establishment of a non-teaching board, who shall examine all those proposing to practice in this Commonwealth. Let the colleges teach and grant degrees if they choose, but let no man practice in Pennsylvania who shall not have been examined by the State Board.

Dr. Benjamin Lee: It is sometimes charged, Mr. President, that bachelor uncles and maiden aunts know, or think they know, more about the education of children than their married brothers and sisters. In relation to the subject under discussion, I confess that I occupy the position of the bachelor uncle. I am not a practical educator; having been compelled, however, to give this question a great deal of serious consideration, my outside stand-point may, perhaps, have had its advantages. But in what little I have to contribute I shall not hesitate to avail myself of the published testimony of those who have had a practical experience in the education of medical and scientific students. A man recently apologized to me, on a street car, for the hilarious conduct of a companion by saying that he had just completed his six years' apprenticeship at the trade of blacksmithing. It made me blush for my profession. I said to myself, it takes but two years to teach a man to perform the manifold and arduous duties of a physician, yet, in the judgment of practical men, six years are required to learn to shoe a horse. It has been truly said by one of the speakers this evening that the medical profession does not now possess the high standing in the eyes of the community of former years. This is evidently owing to the fact that its literary status has deteriorated. But three colleges now demand the requirements held one hundred years ago in this city and country in order to enter upon the study of medicine.

In support of this assertion, allow me to quote for a moment from an introductory address of our distinguished fellow-member, Professor Pepper: —

"The first medical school was founded in 1767, though it is stated by Dr. J. B. Beck[1] that the State of New York is 'entitled to the honor of adopting the first effectual measures for regulating the practice of medicine.' This was in 1760, 'when the General Assembly of the Province ordered that no person shall practice as physician or surgeon in the City of New York before he shall have been examined in physic and surgery, and approved by one of His Majesty's Council, the judges of the Supreme Court, the mayor of the city, or by any three or more of them, taking to their assistance for such examination such proper person or persons as they in their discretion shall think fit.' A fine was attached to infraction of this law. In 1772 a similar law was passed in New Jersey. Those eminent men who formed the University of Pennsylvania boasted — and it was no idle boast — that their scheme of medical education was to have as extensive and liberal a plan as in the most respectable European seminaries, and that the utmost provision was made for rendering a degree a real mark of honor, the reward only of distinguished learning and abilities. This plan was, 'that all such students as have not taken a degree in any college shall, before admission to a degree in physic, satisfy the trustees and professors of the college concerning their knowledge of the Latin tongue, and in such branches of mathematics and natural and experimental philosophy as shall be judged requisite for a medical education.'"

[1] Address before the State Medical Society of New York.

From this it will be seen that not only at that early day was the preliminary examination, which has been so properly insisted on by the lecturer of the evening, demanded, but that it was an examination of an advanced character, including the Latin language, and that high dignitaries of the city were required to be present, and take part in it.

With the multiplication of medical schools, however, the conditions of entrance began to be debased, and the process of deterioration steadily continued until within a very few years, in spite of the earnest and repeated protests of many, both individuals and societies, who had the welfare of the profession at heart. And, in this connection, I confess, Mr. President, that I cannot sympathize with the lecturer in his criticism of the action of the Medical Society of this State in passing "empty" resolutions from year to year, urging a reform in this matter. The American Medical Association, from the first year of its inception, has made this one of the leading subjects of discussion. No State Medical Society has more persistently and vigorously seconded it than that of Pennsylvania. And so far from its efforts having been fruitless, I believe that it is just the agitation, agitation, agitation, of the question, which it has kept up from year to year, which has made such a paper as we have listened to, and such a discussion as we are now participating in, possible this evening. Another result of constant presentation of the subject has been the formation of a society in this county, having for its principal object the elevation of the literary and social status of our profession, by the introduction of a higher standard of education — a society already very respectable in numbers, as it has always been in character. I say, then, all honor to the men who have thus persistently, in the face of discouragement, and often of opposition from the leaders of the profession, year after year, devoted their energies to calling the attention of the profession, of the public, and especially of educators, to this crying evil. Allow me now, very briefly, to quote the opinions of some practical educators on the subjects introduced to our notice. And, first, in reference to the preliminary education: our late venerated fellow-member, Prof. S. D. Gross, than whom no one was better qualified to give an opinion on the subject of education, wrote in 1867: "A sound preliminary education cannot be too strongly insisted upon or too highly prized. It is a boon of inestimable value." Professor Gross enumerates in the preliminary studies English, Latin, Greek, logic, mathematics, history, and geography, such an education as every well-trained scholar should possess, and commends a knowledge of French and German.

Professor Gross took a very gloomy view of the situation.

Dr. Yarnall says: "My distinguished and honored master, Professor Gross, declares: 'The future holds out no promise of amendment. We shall go from bad to worse until the people can stand it no longer, and then we may hope to be able to effect some reform.'"

I cannot share in this pessimistic view. I believe that the reform has already commenced and feel confident that it will go on with increasing impetus.

In regard to the study of Latin: it does not seem to

me that its true value as a factor in education has yet been sufficiently emphasized by previous speakers. It is not for the immense aid which it gives in the ready understanding of technical medical language and nomenclature that it is chiefly useful, but as a mental training, in developing habits of strict thought and application, in teaching the student how to study, how to arrange and utilize the great mass of facts which the strictly technical education will later furnish him, how to sift the numberless theories which will confront him, in short, how to use his mind. This view is amply confirmed by the results of an experiment made upon a grand scale in Germany and lasting over a period of ten years. From 1870 to 1880 students were admitted to the University of Berlin as well from the Real-Schule or scientific schools as from the Gymnasia or classic schools (colleges). The following are the opinions of several of the professors as to the comparative capacities for study and acquirement of those who had enjoyed the advantages of a classical education, and those who had been deprived of them, but had, instead, been trained in certain branches of modern education supposed to be an equivalent: —

The professor of chemistry says, "That students from the scientific schools cannot, in this branch of study, be placed upon the same plane with the students of the gymnasia."

Professor Hoffman observes, "That the matriculates from the non-classical schools often show, at the beginning of their chemical studies in the University, a more rapid progress in acquiring a knowledge of the elementary principles of the science, as well as a greater dexterity in the early practice of chemical manipulation; but that before their studies have advanced very far these relations are reversed, and the non-classical students are left behind."

Professor Rammelsberg gives similar testimony in regard to students in the school of technology. He remarks, "That of those who take his lectures on chemistry during the first semester, the students trained in the gymnasia, though without any previous knowledge of the subject, take a far greater interest in the instruction than that shown by the students from the non-classical schools. At the final examinations the work of the non-classical students is generally inferior to what in advance would be expected, while the work of the classical students is almost invariably better."

Zupitza, the professor of English, says, "That the attainment of the non-classical student is greatly inferior; and what is of still greater importance, they almost invariably show a want of keenness of apprehension and independence of judgment that prevents them from taking any other than a prescribed method." He also testifies, "That, as a member of the Examining Committee of the Government, he has noticed that, although the students prepared in the scientific schools begin their studies of English before they go to the University, their knowledge of the language at the completion of their University course is generally much inferior to the knowledge shown by the classical students."

Herr Mühlenhoff, one of the professors of the German language and literature, uses these expressive words: "According to my experience, it is hopelessly impossible for a student prepared in a scientific school to acquire what may be called a thoroughly satisfactory development. No one ever acquires it through the study of the modern languages; no one ever will, without the solid foundation of a training in a gymnasium."

I submit, sir, that such testimony from those so well qualified to judge, and based upon so extended an experiment, is entitled to profound respect. This verdict was, I may add, concurred in by the scientific as well the classical professors.

DR. JOHN J. REESE: It is late in the day to find it necessary to advocate medical jurisprudence as an integral part of a medical man's education; yet of the ninety colleges in this country but few make it a necessity. Among the majority of these it is an appendage to various chairs, and, in point of fact, is not taught at all. In neither of the two schools here is it held to be a necessary part of education.

DR. JAMES TYSON: Much of the discussion, as well as action, in the matter of higher medical education during the next ten years, will circle about the subject of the admission examination. In my own experience the best and most successful students, who make the most successful physicians, are those who have had the broadest preliminary education. Such an education should include the ancient and modern languages and the natural sciences, as well as physics, and all the branches of a thorough English education. But since it is impossible, at the present day, to insist upon such requirements, we should agree upon a reasonable and practicable preliminary education, which the colleges, through professional opinion, should be required to adopt. It is not to be expected that the average college professor who has reached middle life will initiate a change which at first may effect a reduction in his income.

I hope the influence of the Society will be exerted to change the existing registration law, which requires the medical colleges of the State to indorse, after examination, the diplomas of the extra State graduates desiring to practice in Pennsylvania. This duty should be placed in the hands of a Board of Examiners, independent of the colleges; Indeed, I see no reason why the graduates of our own colleges should be exempt from examination by such a Board. All should be put upon a common plane.

DR. ULRICH, of Chester: Dr. Leffmann objects to the demands made by the State Society; as I happen to be a member of the committee to arrange the subjects for this preliminary examination, it seems proper that I should make some explanation as to the views of that committee. In doing so, I would say that I represented the minimum demand, and Dr. Finley, of Altoona, the maximum. We were in existence for at least two years, making at each meeting a majority and a minority report. Dr. Finley, whose demands were very high, making the minority report. I think the differences in our views were entirely due to the differences in our early educations. I did not think then, nor do I think now, that worthy students should be shut out, though I desire to advance the interest of the profession as much as possible.

At the time this report or programme was under discussion, the late Professor Gross suggested that it would have kept him out if it had then been enforced. No such man could have been shut out; he would have turned back and mastered the requirements. I often, very often, have regretted that my own preceptor had not advised me to a preparatory course; it would have saved me so much labor.

I take issue on the views in favor of specialists, pre-

sented by this lecture, and would object to any special teaching during the general or college course. I have always held that specialists should be well grounded in general medical knowledge, and it would lower my opinion of them to think otherwise. I hold that all specialists should be most thorough physicians. What signifies the ability of a man to diagnosticate an abnormal condition of the eye, ear, uterus, or skin, if he cannot estimate the constitutional relation to either? Mere local treatment is not all that is required in such troubles. There is no question in my mind but that those schools which have adopted the graded course will, in the very near future, command the best pupilage, and the greatest respect for their diplomas.

Dr. Jackson, of West Chester: While I would not be understood as holding that study of the classics was valueless, as a means of mental training, I certainly think that for such purpose it has been relatively too highly valued. Though the experiment of the last decade in Germany was held by the Faculty of the University of Berlin to show that such study best prepared the mind, even for the study of science, it must be remembered that this Faculty undertook the experiment with a strongly expressed prejudice in that direction, and that an opposite conclusion was reached by the Faculties of most other German Universities watching the same experiment. Then, too, the Gymnasia doubtless attracted the better class of students, because their diploma had, for generations, been necessary for admission to the Universities.

It is said that the requirements for the medical degree are not now as high as they have been in the past. This naturally results from the "downward competition" of the schools. A State Board of Examiners, by showing which schools do good work, would establish competition upward, and so raise the standard of medical education.

Dr. Keyser: From the remarks of Dr. Jackson, there would possibly be a misconception in the minds of those present as to the position of the German Real-Schule in the teaching of the classics. Greek, it is true, is not in the curriculum, but Latin is carefully and as thoroughly taught as in a Gymnasium. We have heard much, this evening, in relation to the necessity of a preliminary education before matriculation in a medical school; but another question is, "How are we to change the ever-continual quantity into the more proper quality of graduates of the medical schools.

We should so agitate this question as to cause students to go to the best and highest educational institutions; colleges which admit none but those well fitted by education and proper mental training as their matriculants, and where the teaching is in graded courses, and not the constant repeating of lectures year after year. It is also necessary to look to the final examinations for the medical degree. Let it be stringent, open to public, and in full faculty, instead of the accustomed way of going alone and quietly to the professor's office. No slipping quietly into the profession, as I have several times been informed by some of the graduates of our schools. To raise the standard as it should be we must have the preliminary requirements for matriculation and final examinations for the degree — both high, open and above board at all times.

Dr. Henry Leffmann: In reference to the attitude of the Medical Society of Pennsylvania, my objection is that it has been too tender in dealing with the matter. If it wishes to enforce the schedule of preliminary examination, let it resolve, that after a definite time — say, five years — no person shall be received as a member who is graduate of a college not respecting that schedule or its equivalent.

Recent Literature.

On the Use and Abuse of Pessaries. By George Granville Bantock, M. D., F. R. C. S., Edin. Second Edition. Entirely Rewritten. London. 1884.

This book is an amplification of a paper which first appeared in the *Lancet*, and afterwards was published in pamphlet form. It gives the author's views on the subject of pessaries together with a résumé of the opinions held by the principal gynæcologists. To illustrate the different points discussed in the book illustrative cases are added from the writer's experience.

On the whole the book strikes us as a very fair and intelligent exposition of this much-vexed subject. His position might be thus briefly stated: That a majority of the displacements of the uterus, uncomplicated by adhesions, may, after replacement, be kept in position by a pessary properly fitted to the individual case; that such replacement and adjustment of a pessary will definitely relieve very many symptoms, and that in a large proportion of cases a permanent cure is effected, and the pessary may be dispensed with.

For the author's special views on the relative frequency of the different displacements, on the way in which pessaries act, on the value of the stem pessary, and on a good many other kindred subjects, we would refer to the book itself, which will well pay perusal. The author is a man of large experience, and his cases illustrate the conscientious care which has doubtless contributed so largely to his success in this special line of treatment. His book can be recommended to the profession as a very safe guide.

Manual of Physiology, a Text-Book for Students of Medicine. By Gerald F. Yeo, M. D., F. R. C. S., Professor of Physiology in King's College, London, etc. Philadelphia: P. Blakiston, Son & Co. 1884. Pages xxiv., 749.

The modern publisher does not believe with the ancient Preacher that "much study [reading] is a weariness of flesh," and so Dr. Yeo has been persuaded, he informs us in his preface, to prepare this volume. He has no new tale to tell, no new point of view to develop, no "epoch making" presentation of any portion of the subject to give us; his only object has been to prepare a book which the first year's student shall find profitable reading. Once admitting the necessity of such a book it must be acknowledged that Dr. Yeo has excellently carried out his plan. The plan itself is such as to render any detailed criticism of the book unnecessary; in fact the most serious objection to be made to the book is that its goodness and size, with the expense and apparent completeness which that involves, will hinder many students from buying larger and better books after they shall have read this. It is but fair to say here, what we have had occasion to say before, that the kind of medical student Dr. Yeo seems to write for has great need to learn practical logic somewhere, and it will be much better if he do so in his physiology rather than to wait for the more laborious and dangerous experiences of his private practice.

This is one reason why all *large* books on physiology which profess to be but elementary are objectionable. This said, we have nothing but commendation for what Dr. Yeo has done in carrying out his plan. He has avoided theory with success — sometimes perhaps too completely. The book is liberally illustrated, many plates having been taken from the other sources, but are most commendably repeated as required. The plates in the American reproduction are not all of them very successfully printed. The text is much better printed, the only error which has attracted our attention is "*nitrate* of amyl" (p. 403). The index and the glossary are pretty full; the latter would be more acceptable to many students if it were liberally accented.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 6, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number: $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

HYDROCHLORATE OF COCAINE AS A LOCAL ANÆSTHETIC.

AT the Ophthalmological Congress held in Heidelberg in September last Dr. Koller demonstrated the properties of cocaine, the alkaloid of coca, in temporarily abolishing the sensibility of the eye. Naturally the demonstration excited great interest, and the study of the alkaloid has been pushed with vigor. As yet the enthusiasm among ophthalmologists over the new anæsthetic has received no check, and seems rather on the increase, as proofs accumulate of its successful action. If the place which it promises to fill in ophthalmic therapeutics becomes assured, the introduction of the drug will mark an era in the surgery of this branch hardly less important than that ushered in by the discovery of anæsthesia by ether.

The drawbacks to the use of general anæsthesia are peculiarly prominent in operations on the eye, and in this of all surgical branches a reliable local anæsthetic possessing no injurious qualities is a desideratum. Up to this time no drawbacks to the use of cocaine have been reported, and it has been used in a variety of operations with results so uniform as to justify the statement that it is an unqualified success, producing local anæsthesia so complete that no form of contact is perceived, the mind and muscular power being left unimpaired. When we remember that in all cases reported up to the time of writing this result has been attained without unpleasant or detrimental after-effect, and with no element of danger, we can fully appreciate the enthusiasm of those members of the profession who have occasion to make use of this valuable discovery.

But there is no reason to suppose that the field of usefulness of cocaine as an anæsthetic will be limited to ophthalmology. Already for some time in use in laryngology, it has been of late tested to a certain degree on the nasal, buccal, urethral, and rectal mucous membranes, as well as in the ear, with results pointing towards its use in almost unlimited directions. It would seem to merit a thorough trial at the hands of the dental profession, for example, in the way of application during excavation, for there is every reason to believe that success may be attained in this direction, especially with exposed nerves.

The American profession has reason to congratulate itself on the alacrity with which the discovery has been assimilated and put on a practical basis in this country.

One needs but a short experience in medicine to learn to receive the first accounts of a new remedy or of a new application of an old one with some hesitation. A thing powerful for good is quite sure to have some limitation to its use, and with powerful remedial agents we are obliged to learn to secure the therapeutic and avoid the toxic effects. What drawbacks to the use of cocaine the future will develop cannot be foreseen; that none should be found is too much to expect.

ONE FEATURE OF THE RHINELANDER CASE.

AN important decision has just been rendered in New York in regard to the matter of insanity under the present Penal Code, by Recorder Smyth, in the case of William C. Rhinelander, who shot the lawyer, John Drake, last summer. A commission of three, including one physician, Dr. Detmold, recently decided by a majority vote that the prisoner was insane; but in this decision one of the commissioners did not concur. The District Attorney claimed that the determination of the Commissioners was conclusive, and that the only duty of the court was to grant an order committing him to the State Lunatic Asylum; but the Recorder, after a careful review of the case, now decides that Rhinelander is sane and must stand trial for the shooting. In his opinion, founded on a study of the statutes relating to commissions of lunacy in the cases of criminals, and the construing together of sections 658 and 659 of the Code of Criminal Procedure in the light of the common law (as they are apparently contradictory in terms), he declares that the determination of a commission is not final, and that the court has full power to review it and the proceedings on which it is based, and to adopt or reject it, as the evidence and the law may require.

In the course of his opinion Recorder Smyth thus expresses himself in regard to the expert medical testimony submitted in the case: —

"I agree with the learned commissioner (the dissenting one) that the expert evidence is of no value in this investigation. While the physicians called by the people to sustain the allegation of insanity say that the defendant is insane, they differ radically among themselves as to the classification of that al-

leged insanity. Two say that he has general paresis, one says that he is an imbecile, and another that he suffers from melancholia. . . . But whatever may be the views of the learned experts I have searched in vain through all their evidence to find any convincing proof of any one act of the defendant during the period embraced in the examination which itself proved insanity. Particular instances of foolish and impetuous acts, committed at long intervals, some of which being such as any self-willed or impulsive person might under certain circumstances do, cannot prove actual unsoundness of mind, and a general judgment passed to-day upon the quality of an isolated act, committed years ago, is of but little value in determining a question of present sanity."

We draw attention to this decision not only for its bearings upon the medico-legal questions of insanity, but also because it has so marked a bearing on the character of expert witnesses. Testimony subject to such a revision must be in reality worthy of respect to receive any consideration. Incompetent witnesses will hardly be in favor or care to appear. It seems to bid fair to help establish the distinction between expert and pseudo-expert witnesses.

PREVENTIVE MEDICINE FOR THE AUTUMN.

THE transition seasons of our American climate, corresponding in a general way with the periods of the year which the world has agreed to call spring and autumn, but more exactly with the early months of April and May, and the later ones of September and October, are characterized by sudden and violent oscillations of temperature. A change of twenty or thirty, and even more degrees, of Fahrenheit in the twenty-four or forty-eight hours is by no means phenomenal. These months bring with them a certain malaise exhibiting itself in general lassitude, and a certain class of maladies marked by local congestions — such as sore throats, nasal, bronchial, and intestinal catarrhs — which are familiar and expected, if not welcome visitors.

The extreme changes of temperature are, of course, peculiarly dangerous to the very old and the very young, that is, to those whose vitality and power of adaptability and resistance are especially limited. But in so far as the active and vigorous are less careful or less cared for than this former class, they, too, are liable to the penalties exacted by exposure to these climatic freaks.

To a certain extent an unremitting attention to the daily bulletins of the weather-bureau and a constant eye upon the barometer and thermometer give us an advantage over a preceding generation. But the leisure and ability to observe and profit by these warnings are not given to all, and even of those who are fortunate enough to possess a varied wardrobe and to live in a well ordered house, many prefer to run the risks of a chill or a sweat to numberless changes of outer and inner clothing and almost hourly directions about house heating and ventilation.

It must be confessed that practically American flesh must still consider itself, notwithstanding modern improvements, inevitably heir to a certain number of these afflictions. There are, however, a fair proportion which, without undue self-solicitude, may be escaped, and we desire to call attention, in the interest of preventive medicine, to one fertile source of headaches, sore throats, and diarrhœas peculiar to the months of September and October, which a very moderate degree of forethought might easily eliminate altogether. We refer to the reoccupation, without proper preparation, in the autumn, of houses and apartments which have been shut and vacant during the summer.

The custom of leaving the cities for the country or sea-shore during a certain number of summer weeks or months is becoming every year more general among a larger class of our city populations, and not only that but every year the length of the period of absence is increasing. Now the return to town from the country, the exchange of the open air for the house, of the fields, or the beach, or the piazza for the pavements and the streets, of an active life for a sedentary one is of itself a sufficient shock to the sensibilities of any one's system, however accommodating. But when, in addition to this inevitable shock, the individual or family neglects to secure such mitigations of the conditions as are easily within every one's reach, a cry of distress from the overtaxed constitution is, it must be allowed, indeed justifiable.

It is too common to return to a town house which has been closed and uninhabited without taking the simple precautions of thoroughly ventilating the rooms and passages, and flushing the drains. This ought always to be done, and physicians should remind clients who are too careless to think of these things for themselves.

November would be a less solemn month than it now is were these simple precautions taken in September and October, and many a case of febricula, or typhoid fever even, for which the country is now held responsible, would be averted altogether.

MEDICAL NOTES.

— We learn with regret that Professor Huxley has become so worn by his multitudinous labors that he has been ordered by his medical attendant to leave England for some months of perfect quiet and freedom from work.

— The prescription ℞ Aerismaris, which was formerly supposed to necessitate a pilgrimage to the shore, can, it seems, be filled by any inland apothecary. Dr. B. W. Richardson, who nearly a score of years ago called attention to the possibility of getting a sea atmosphere without going near the ocean, has recently revived his suggestion in the *Asclepiad*. The pharmacy of the prescription is as follows: The solution to be used and diffused as spray consists of peroxide of hydrogen (ten volumes strength), containing one per cent. of ozonic ether, iodine to satura-

tion, and 2.50 per cent. of sea-salt. The solution, placed in a steam or hand-spray diffuser, can be distributed in the finest spray in the sick room at the rate of two fluid ounces in a quarter of an hour. It communicates a pleasant sea odor, and is the best purifier of the air. It is also a powerful disinfectant. A large spray-producer has been recently invented which will diffuse the artificial sea air through a hospital ward.

— The proposition has been made in the general medical council of Great Britain to raise the limit of age at which legal qualification to practice medicine shall be obtainable. A definite motion to fix the age at twenty-three years was, however, rejected.

— Broad streets are not, it seems, the unmixed blessing that might be *a priori* supposed. For instance, in the State of Illinois the excessive width of the streets is reported as having of itself become a source of nuisance and of danger to health. Sixty feet and more are ordinarily given to new streets even in the smaller towns. Eight feet on either side are paved and devoted to pedestrians, and the remaining space, varying usually from forty-four to fifty-four feet, is devoted to carriage traffic. The result is that this wide carriage road, so often in excess of the requirements of the vehicles that have to travel over it, becomes a source of such expense as to forbid its being properly paved, cleansed, and channeled. The street consequently is soon turned into a vast surface of dirt mixed with filth, horse droppings, and other refuse, and when the weather is so dry that dust is formed the air which is inhaled as the dust flies about is calculated to cause disease as well as discomfort instead of promoting the health of pedestrians. Dr. Gregory in bringing forward this subject fully concurs in the great importance of providing wide thoroughfares, and of keeping the number of inhabitants to each acre down to a proper maximum, and hence he declares that he would not on any consideration diminish by a single foot the width of the streets, but he would curtail the actual roadway so that it shall only suffice for the proper demands of the carriage traffic, and between that limited space, which could then be properly kept at a reasonable cost, and the foot-paths he would plant trees and lay down grass, so as really to provide in towns and cities such freshness and greenness as would go far to induce people to take that form of exercise which is most conducive to health.

— A case was reported to the *Société des Sciences Médicales de Lyon* (*Lyon Medical*, 5th October), in which *lavage* was applied to the removal of a foreign body from the stomach. A pin had been swallowed by a dressmaker, and emetics, cathartics, etc., freely used for a week, had failed to dislodge it. The point could be felt by the patient giving a pricking feeling at the epigastrium, and it was believed by the physician that the pin had become caught in a fold of the mucous membrane. He accordingly washed out the stomach by means of a large tube (fifteen millimetres external diameter), using fifteen litres of water. The washing did not bring away the pin, though after it the patient felt relieved of the pricking sensation, and soon after vomited it. It was twenty-five millimetres long. It was believed by the operator that the washing dislodged the pin from its resting place and enabled it to be ejected by the act of vomiting.

— An interesting case having an important bearing on the question of the marriage of syphilitic subjects is reported by Mr. Cooper Forster, in the *Lancet*, August, 1884: A man, aged thirty, had a hard chancre in 1862; he was treated for four months with mercury and iodide of potassium, and from 1863 until the spring of 1882 he had no symptoms of syphilis. In 1865 he married a strong, healthy girl, who aborted four months afterwards, after having had sores on the vulva, sore throat, and a copper scaly rash. In May, 1866, a seven months' child was born, with marked symptoms of syphilis; this died in ten weeks. In May, 1868, the wife was again pregnant, when she was suddenly seized with difficulty of breathing, and died before medical aid was obtained. In 1872 the patient married again, his second wife miscarried at the sixth month, but did not again become pregnant for some years. In 1876 the patient and his wife were put under a course of mercury and iodide of potassium for over two months. In 1878 a healthy eight months' child was born, and in March, 1880, a healthy child was born at full time. In January, 1881, the husband had a fall, the effects of which he felt for a time, and then they passed off. In the spring he showed signs of locomotor ataxy, and in the autumn of 1882 he died, in spite of treatment with mercury and iodide of potassium.

— An unusual case of congenital hypertrophy of one foot is recorded by Dr. Blakader, of Montreal, in the *Archives of Pediatrics* (October 15th) with figure. The relative size of the two feet may be seen from the following table: —

	Normal foot. January.	Hypertrophied foot. January.
Length (inches)	4	5¼
Circumference around ball of foot	4¼	7½
Circumference around heel and ankle	6	6⅝
Circumference around calf	7	7¼
Circumference around thigh	9	9¾

As the hypertrophy was increasing an operation was resorted to, and the second and third toes, with the anterior two thirds of the metatarsal bones, were removed. The tumor proved to be a diffuse lipoma, with hypertrophy of cartilages and tendons.

NEW YORK.

— The members of a medical commission which has recently visited the cow stables at Blissville, Long Island, where pleuro-pneumonia has prevailed at intervals for quite a long time, are of the opinion that the only way to effectually suppress the disease is to burn the old buildings now used for stables.

— At the recent annual meeting of the Society of St. Luke's Hospital the report of the Board of Managers showed that during the year ending Saturday, October 18th, there were treated in the institution 1497 patients, of whom 129 died, and 601 were discharged cured. Of the whole number 1190 were charity patients. The average daily number of patients was 155,

and the total number of days of hospital care was 56,691 — an average of more than thirty-seven days to each patient — of which 47,090 days were gratuitous. The average daily cost of treatment per capita was 1.21\frac{1}{10}$. During the year legacies amounting to $32,560, and donations for the endowment of free beds to the amount of over $13,000, were received. In addition, Mrs. James Morris endowed the hospital with a special fund, the income of which is to be used in providing vocal and instrumental music for the chapel and wards. The total income from endowments was $28,645.53, which, added to the sum received from paying patients, amounted to about half the sum required for the support of the institution.

— The Montefiore Home for Chronic Invalids, at the corner of Eighty-fourth Street and the Eastern Boulevard, was formally opened on the 26th of October. Sir Moses Montefiore was the first contributor to the institution, and the Jewish residents of New York furnished the remainder of the fund for its support.

— At the annual meeting of the County Medical Society (New Code), held October 27th, Dr. Daniel Lewis was elected President; Dr. Lawrence Johnson, Vice-President; Dr. W. M. Carpenter, Secretary, and Dr. O. B. Douglas, Treasurer. Two *homœopaths* who had applied for membership in the Society were *unanimously* elected.

— At the competitive examination for the positions of first and third assistant physicians at the State Hospital for the Insane at Poughkeepsie, held October 22d at the building of the New York Academy of Medicine, thirteen candidates presented themselves. The Examining Board consisted of Mr. Silas W. Burt, Chairman of the Civil Service Commission, Dr. Stephen Smith, State Commissioner in Lunacy, Prof. Henry Drisler, of Columbia College, and Drs. James R. Leaming, E. Darwin Hudson, J. A. McLean Hamilton, Theodore H. Kellogg, A. N. Bell, and A. E. MacDonald. On the day following the candidates were tested in regard to their practical knowledge of insanity in the wards of the City Insane Asylum on Ward's Island, by Dr. MacDonald, the Superintendent. The names of the successful competitors have not yet been announced.

— At the Academy of Medicine, on the 22d ult., non-competitive examinations for Superintendent of the Asylum for Idiots at Syracuse, at a yearly salary of $3,000, and for the position of assistant physician at the Willard Insane Asylum, at a salary of $1800, were also held.

— The wife of a citizen of Waterford, New York, has presented her husband with four children at a birth. They are all girls, and are said to have weighed seven pounds apiece when born.

— The Board of Health asks an appropriation of $437,408 for its expenses during the year 1885; but the Board of Estimate and Apportionment has reduced this amount by $17,126.

— Dr. James Faulkner, who died at Dansville, Livingston County, on the 19th of October, would have been ninety-five years old had he lived to January 21, 1885. He was born at Cambridgetown, Washington County, and served through the war of 1812 as a surgeon in General McClure's command. After the war he gave up the practice of medicine and engaged in business. He also entered public life, holding many positions of trust and honor, and at the time of his death was the oldest bank president in the United States.

— Dr. Allen S. Church, a well-known and highly respected New York physician, and Treasurer of the County Medical Association, died October 24th.

Correspondence.

"WEIGHT AS AN INDICATION OF THE CHARACTER OF RISKS FOR LIFE INSURANCE."

Augusta, Me., *October* 25, 1884.

Mr. Editor, — The article in this week's Journal on "Weight as an Indication of the Character of Risks for Life Insurance" is interesting and suggestive, and its conclusions may be and probably are correct, but it seems to me to furnish an additional example, where we had enough already, of the fallacy of statistics and of reasoning from insufficient premises. If the conclusions are correct they are so independently of the data furnished in the paper. In order to acquire any value they must be supplemented by tables showing the number of members of the Society who are *at*, *below*, and *above* the normal weight, and what proportion of these vary fifteen per cent., twenty per cent., etc., from the standard. As the paper now stands it does not show that the death-rate is any higher among those whose weight varies from the standard than among those of standard weight.

As medical examiner of three of the largest life companies and a large beneficiary organization I am greatly interested in this subject, and wish that Dr. Seaverns, from the material at his command, would furnish us some statistics of real value.

Yours truly, J. O. Webster, M. D.

Roxbury, Mass., *October* 28, 1884.

Mr. Editor, — I cheerfully concede the imperfections of my article as referred to by Dr. Webster, for it was prepared in haste at a time when I was much fatigued.

It would, no doubt, be interesting and valuable to collect, as he suggests, tables of the members of our Society who are at, below, and above the normal standard of weight, but on the 1st of March last there were 48,912 of such members, and life is short.

I do not claim that my statistics *prove* anything *conclusively*, and it is very seldom that any statistics in medicine do more than establish a probability; and if (as I think my data show) among the 900 or more deaths it appears that a large proportion of those light in weight die of consumption and other wasting diseases, and if among the heavy weights many of them die of diseases of the circulatory system, there is, *probably*, a special tendency of the one class to the one form of disease, and of the other class to the other form of disease. And since phthisis is confessedly one of the most fatal diseases encountered in life insurance, I think I am justified in inferring that the examiner should be especially on his guard against those whose

light weights show that they have a special proclivity thereto.

I am obliged to Dr. Webster for his courteous criticism.

Yours very truly,

JOEL SEAVERNS.

Miscellany.

LOCAL TEMPERATURE IN BILIARY COLIC.

DR. JULES CYR calls attention to the diagnostic value of local thermometry during the attack, in a monograph that has recently appeared (*Traité sur l'Affection calculeuse*, Paris, 1884).[1] If, during the paroxysm, the thermometer be applied to the area of greatest pain there is observed a local rise of a quarter, half, or even one degree centigrade above the normal temperature of the region. This local rise may, indeed, reach the level of the axillary temperature, which, under normal circumstances, is a degree and a half higher than that of the epigastrium or the right hypochondrium. This fact was first brought to the notice of the profession by Professor Peter, at La Charité, in whose service the author had, in March, 1883, the opportunity of observing an interesting case, of which the following particulars are stated: A young woman, confined for two or three years to bed by disease of the spine, was seized during her sojourn in the hospital, and at the end of the second year of decubitus, with a paroxysm of biliary colic, which was speedily followed by others of a like kind, one of which was attended by jaundice. The trace which displayed the axillary temperature, that of the left hypochondrium, and that of the right hypochondrium, during a period of three months, demonstrated (1) a constant parallelism between the elevation of the axillary temperature and the elevation of that of the right hypochondrium; (2) in the periods in which the attacks of biliary colic were absent the tendency to a uniform temperature in the two hypochondriac regions, sometimes without appreciable difference, sometimes with a variation of a quarter or a half degree C.; (3) during the paroxysms the temperature of the right hypochondrium was higher than that of the left to the extent of 1° C. to 1.3° C. It sometimes attained, and on one occasion even exceeded, that of the axilla. In a second case, where the focus of pain was in the epigastrium, the temperature at this point, which had been 36.1° C., rose to 37.8° C. and 37.9° C., while the axillary temperature varied between 36.6° C. and 37.5° C. In a third case, characterized by violent and frequent almost quotidian paroxysms, the temperature of the right hypochondrium almost always exceeded that of the axilla of the same side. This element of symptomatology, heretofore overlooked, M. Cyr has, on several occasions, studied, with the result of fully confirming the observations of Professor Peter. He has, further, found the difficulties attending the application of the surface thermometer, under the circumstances, less serious than he was at first led to expect that they would prove. Pain constitutes the essential element of the paroxysm of biliary colic. Other phenomena accompanying it are accessory, and may all be absent in particular cases, for their presence is dependent upon circumstances not at all necessary to the paroxysm. To this general statement, however, it appears that an exception may now be made in favor of the local elevation of temperature. This, in the absence of any cause beyond the paroxysm adequate to explain it, constitutes an important element of diagnosis, especially when we consider that in gastralgia and intercostal neuralgia — maladies in many respects closely resembling the attack of hepatic colic — local elevation of temperature does not occur.

STRICTURES.

WE find in a small volume entitled Medical Rhymes, recently compiled by Dr. Hugo Erichsen from various sources, the following stanzas, published originally in the *Western Lancet* in 1857. As they are probably unfamiliar to our readers we reproduce them. They purport to have been "left on a doctor's table by a patient who was about to start for Niagara Falls, where the water runs down hill with nothing on earth to hinder it."

"When sorrow's cloud is cast athwart
The sunshine of my mind,
When I with gloomy care distraught
No recreation find;
When sighing o'er my hapless lot
And what I used to be,
I 'll seek some quiet, tranquil spot,
And pass a small bougie.

"Let strictures on my conduct pass,
Unnoticed let them be;
A stricture somewhere else, alas!
Is more deplored by me.
In hope this blight on manhood's bloom
I yet effaced may see,
I 'll hie me to my quiet room,
And pass a small bougie."

AN UNUSUALLY PROTRACTED CASE OF DIPHTHERIA.

THE *Archives of Pediatrics* (October 15th) quotes from the *Revue Mensuelle des Maladies de l'Enfance* (July, 1884), a remarkable case, by Wins, in which diphtheria lasted seventy days.

"The author refers to the fact that Cadet de Gassicourt, Empis, Barthez, and Isambert have already recorded cases of diphtheria which lasted much longer than its usual duration, and adds in his paper a similar case which occurred under his observation. The case occurred in a child six years of age. A general eruption was present for nine days, at the end of which period there was pain in the throat, with elevation of the body temperature. Two days later a false membrane appeared upon the left tonsil, then the right one, and the pillars of the pharynx became involved, and the cervical glands enlarged. After twelve days the false membrane disappeared, but an abscess formed in the right cervical region. This was opened and soon healed. The urine contained a small quantity of albumen, but this disappeared with the disappearance of the false membrane from the pharynx. During the course of the angina a diphtheritic patch two centimetres in diameter appeared upon the left side of the lower lip. Three days later two new patches appeared upon the right side of the lip. These remained for a short time and were then replaced by others, the process continuing until the seventieth day from the beginning of the disease, when they disappeared entirely, without recurrence. These membranes upon the lip were thin, grayish in color, developed upon a red base without consequent ulceration, and were not attended with pain or

with difficulty of mastication. After the general disease had disappeared, these secondary phenomena appeared to be entirely local, being unattended by elevation of temperature, or by albuminous urine. The child did not recover his accustomed health and spirits, however, until the final disappearance of the patches upon the lip. The author agrees with Cadet de Gassicourt in his opinion that the danger in these protracted cases of diphtheria depends exclusively upon the location of the diphtheritic phenomena."

REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 25, 1884.

Deaths reported 2550 (no reports from Buffalo, Pittsburg, and Milwaukee): under five years of age, 1019; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 664, consumption 367, diphtheria and croup 223, diarrhœal diseases 201, lung diseases 197, typhoid fever 93, malarial fevers 60, scarlet fever 39, whooping-cough 24, cerebro-spinal meningitis nine, measles eight, erysipelas three, puerperal fever three, typhus fever one. From *malarial fevers*, New York 14, New Orleans 13, Brooklyn eight, St. Louis seven, District of Columbia nine, Philadelphia and Baltimore two each, Chicago, New Haven, Nashville, and Charleston one each. From *whooping-cough*, New York 12, Brooklyn six, Boston three, Baltimore, District of Columbia, and Somerville one each. From *cerebro-spinal meningitis*, New York six, Philadelphia, Charleston, and Fall River one each. From *measles*, New York four, Cincinnati two, Brooklyn and Gloucester one each. From *puerperal fever*, Chicago, Boston, and St. Louis one each. From *erysipelas*, Brooklyn, Chicago, and Boston one each. From *typhus fever*, Chicago one.

Cases reported in Boston: scarlatina 45, typhoid fever 44, diphtheria 24, and measles eight.

In 105 cities and towns of Massachusetts, with an estimated population of 1,332,401 (estimated population of the State 1,955,104), the total death-rate for the week was 17.70 against 17.62 and 17.84 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending October 18th, the death-rate was 21.1. Deaths reported 3545: infants under one year of age 946; acute diseases of the respiratory organs (London) 286, diarrhœal diseases 167, scarlet fever 74, fever 68, whooping-cough 56, measles 39, diphtheria 33, small-pox (London 10, Sunderland two, Birkenhead and Liverpool one each) 14. The death-rates ranged from 13.6 in Halifax to 30.2 in Bolton; Birmingham 17.0; Bradford 20.7; Leeds 23.9; Leicester 21.6; Liverpool 28.2; London 19.7; Manchester 23.6; Nottingham 23.9; Sheffield 24.3; Sunderland 23.3. In Edinburgh 18.2; Glasgow 23.1; Dublin 30.2.

For the week ending October 11th, in the Swiss cities, there were 20 deaths from consumption; diarrhœal diseases 14, lung diseases five, diphtheria and croup two, erysipelas two, puerperal fever two, small-pox one, scarlet fever one, typhoid fever one. The death-rates were, at Geneva 5.1; Zurich 3.9; Basle 15.5; Berne 15.5.

The meteorological record for the week ending October 25th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY FROM OCTOBER 25, 1884, TO OCTOBER 31, 1884.

ALDEN, CHARLES H., major and surgeon. Relieved from duty at Fort Yates, D. T., and ordered for duty at Fort Snelling, Minn. S. O. 125, Department of Dakota, October 20, 1884.

ALDEN, C. H., major and surgeon. In addition to his duties at Fort Snelling, Minn., to perform the duty of attending surgeon at department headquarters. S. O. 127, headquarters Department of Dakota, October 23, 1884.

WILSON, W. J., captain and assistant surgeon. Assigned to temporary duty at Fort Trumbull, Conn. S. O. 220, Department of the East, October 27, 1884.

CORBUSIER, W. H., captain and assistant surgeon. Assigned to duty at Fort Bowie, A. T., S. O. 99, Department of Arizona, October 22, 1884.

LAGARDE, L. A., captain and assistant surgeon. Assigned to duty at Fort Ellis, M. T., relieving First Lieutenant G. E. Bushnell, assistant surgeon U. S. A., who, upon being relieved, will report for duty at Fort Snelling, Minn. S. O. 126, Department of Dakota, October 22, 1884.

EVERTS, EDWARD, first lieutenant and assistant surgeon. Leave of absence extended one month. S. O. 107, headquarters Division of the Pacific, October 21, 1884.

MCCAW, WALTER D., first lieutenant and assistant surgeon. Ordered from Fort Craig, N. M., to Fort Wingate, N. M., for duty. S. O. 92, headquarters District of New Mexico, October 21, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING NOVEMBER 1, 1884.

BEARDSLEY, GROVE S., surgeon. To Washington, D. C., for examination preliminary to promotion and as to qualifications for sea duty. October 31, 1884.

CRAIG, THOMAS C., passed assistant surgeon. To the Alliance for temporary duty. October 31, 1884.

GARDNER, JAMES E., passed assistant surgeon. To the Naval Hospital, Norfolk, Va. October 28, 1884.

HALL, JOHN H., passed assistant surgeon. From the Naval Hospital, New York, to the Navy Yard, Mare Island, Cal. October 29, 1884.

HORD, WILLIAM T., medical director. To continue duty as member of the Retiring Board until January 1, 1884. October 27, 1884.

LOVERING, P. A., passed assistant surgeon. To the Naval Dispensary, Washington, D. C., for temporary duty. October 27, 1884.

TURNER, THOMAS J., medical director. To continue duty as member of the Retiring Board until January 1, 1884. October 27, 1884.

STEELE, JOHN M., passed assistant surgeon. To the Naval Hospital, New York. October 29, 1884.

MASSACHUSETTS MEDICAL BENEVOLENT SOCIETY. — By invitation of the Faculty the annual meeting of the Society will be held at the Harvard Medical College, Boylston Street, on Thursday, November 6th, at 3.30 P. M. Members will have an opportunity to inspect the new building.

HENRY W. WILLIAMS, *President.*

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The next regular meeting will be held on the second Thursday of November, at the Medical Library Rooms, No. 19 Boylston Place, at four o'clock, P. M. A paper on Treatment of Uterine Flexions will be read by Dr. A. P. Clarke. Discussion will be opened by Dr. L. F. Warner.

H. J. HARRIMAN, M. D., *Assistant Secretary.*

DEATHS.

DIED, — At Dorchester (Boston), Mass., October 31, 1884, Edward Jarvis, M. D., M. M. S. S., aged eighty-one years.

At Marlborough, Mass., October 31, 1884, Nathan Savery Chamberlain, M. D., M. M. S. S., aged thirty-nine years.

BOOKS AND PAMPHLETS RECEIVED. — The Science and Art of Surgery. A Treatise on Surgical Injuries, Diseases, and Operations. By John Eric Ericksen, F. R. S., LL. D., F. R. C. S., Eighth Edition. Revised and Edited by Marcus Beck, M. S. and M. B. London, F. R. C. S. With 984 Engravings on Wood. Vol. I. Philadelphia: Henry C. Lea's Son & Co. 1884.

A Practical Treatise on Fractures and Dislocations. By Frank Hastings Hamilton, A. B., A. M., M. D., LL. D. Seventh American Edition Revised and Improved. Illustrated with 379 Wood-Cuts. Philadelphia: Henry C. Lea's Son & Co. 1884.

The Brain and the Nerves: Their Ailments and their Exhaustion. By Thomas Stretch Dowse, M. D., F. R. C. P. E., etc. New York: G. P. Putnam's Sons. 1884.

Diphtheria Spread by Adults. By A. Jacobi, M. D. (Reprint from New York Medical Journal.) 1884.

Address in Ophthalmology. Delivered before the Medical Society of the State of Pennsylvania by W. S. Little, A. M., M. D., of Philadelphia, at its Annual Meeting, held at Philadelphia, May, 1884. (Reprint from its Transactions.)

Annual Report of the Secretary of the Navy for the Year 1883. In Two Volumes. Vol. II. Washington, D. C. 1883.

Lectures.

ÆTIOLOGY AND PROPAGATION OF CHOLERA.

LECTURE DELIVERED BEFORE THE SOCIETY OF ARTS, OCTOBER 23, 1884.

BY GEORGE B. SHATTUCK, M. D.,
Visiting Physician Boston City Hospital.

GENTLEMEN, — The subject to which your attention is asked this evening is the origin or cause and the mode of propagation or progression of cholera. Under the first head I shall touch upon the history of the disease, and under the second upon the measures adopted for its control, hitherto known under the generic name of quarantine. I shall try to condense what I have to say intelligibly within the limits of your patience, and at the same time take a broad, philosophical view of this great epidemic disease, avoiding as far as possible the details peculiar to local outbreaks.

Great epidemic diseases like the plague, like yellow fever, like cholera, have their rise, their culmination, their decline, just as great races, great social movements, or great religions have; and there is being gradually evolved a philosophical epidemiology, as there is a philosophy of ethnology, of sociology, of history. An individual outbreak of an epidemic bears the same relations to this as does a great battle to the fortunes of a race or form of civilization. Its signification lies in the causes which led up to it, and in the lessons it leaves, not in the number of killed and wounded or the names of the victors and vanquished.

In epidemiology, as in other departments, there are some matters of fact upon which authorities are agreed, some upon which they differ, and some matters of opinion and observation which are being now actively prosecuted, and I shall try to keep them separate.

Cholera has its myths and mythology, which need not detain us. It is thought by some to be one of the most ancient diseases of which distinct descriptions exist, and in support of this passages are cited from Hippocrates, from writers in Sanskrit, from Celsus, Aretæus, Galen, and plenty of other ancients; but the same thing is said with the same uncertainty of interpretation in regard to syphilis and other comparatively modern maladies. There is but little doubt, however, that cholera, as it presents itself to-day, has prevailed in India, in the province of Bengal, in the delta formed by the mouths of the Ganges and Brahmapootra Rivers for an indefinite period — perhaps as long as the human race itself. There, as is now generally agreed, is its home, there it is indigenous, there it is endemic, as the plague still is in Asia Minor or yellow fever in Havana, and from thence it starts out periodically to invade the civilized countries of the Western Hemisphere as did the plague from its home in the Middle Ages.

The reliable history of cholera, with which alone we will concern ourselves, dates back scarcely farther than the middle of the last century, when the English began to occupy India, and it is only since the beginning of this century that any really accurate records of its movements are to be found.

The first world-famous epidemic extending beyond the limits of Bengal was that of 1817. This was a year for one of the great twelfth yearly festivals or pilgrimages which are held every year in all parts of India, but increase in sanctity every third, sixth, and ninth year, and still more every twelfth and sixtieth year. It was also a year of marked climatological peculiarities. This epidemic traveled slowly, in conformity with the means of communication in India at that time, but in the course of six years it covered nearly the whole of Asia and a large part of India, moving especially toward the northwest, and reaching the borders of Persia and Arabia in 1822–1823. From this time there was a period of comparative quiescence for two or three years, but in 1825–1826 it was again on the march, and in August, 1829, the first fatal case of cholera occurred in Europe at Orenboorg, a town in the Russian Ural, on the borders of Tartary, and on the line of the caravans trading with China, Persia, and the East. The disease had now reached virgin soil and comparatively rapid modes of transit, and soon availed itself of its privileges.

In September of 1830 Moscow was attacked, and St. Petersburg in June of 1831, by which time it had already spread through Poland, and presented itself at Prussian towns on the Baltic. England was reached from Hamburg in October of this year, London being attacked in January, Edinburgh in February, and Dublin in March of 1832, in which month — crossing from England to France — it showed itself at Calais and at Paris, pursuing this same course in the epidemics of 1849 and 1853. It crossed the Atlantic with emigrants, and presented itself in the St. Lawrence River at the end of April, though not heard of as spreading in Montreal and Quebec until early in June. New York is suspected of having received the disease about the same time, but if so it was unacknowledged, and quarantine records for the months of April, May, and June of that year are, strange to say, not to be found.

This epidemic was especially severe in Canada, from whence it crept down the valley of Lake Champlain and the Hudson River, and attacked towns on our northern frontier by July, among the earliest Detroit. Some of the earliest cases of the disease in this first invasion of our country are said to have followed the stranding of a brig on the coast of South Carolina. Eventually all the cities of the Atlantic sea-board were invaded, but Boston and Massachusetts practically escaped.

New Orleans was reached in November, and Mexico invaded in the summer of 1833. In the mean time having remained quiescent in Europe it again broke out in epidemic form in June, 1833, this time in Portugal, and prevailed in one country or another until toward the end of 1837. Having prevailed in India and Persia during the interval, it again broke out in Europe in 1847, the first case occurring at Constantinople. During 1848 cholera traveled nearly all over Europe, entering England as before from Hamburg, and reaching Paris in March of 1849. It reached the United States this time almost simultaneously at New York and New Orleans early in December, 1848, the disease at each place being introduced by German emigrants, sailing themselves in good health from an unaffected port — Havre — but bringing infected clothing, which, on account of changes in the weather, was unpacked on the voyage. The first cases occurred when the vessels had been sixteen and twenty-seven days at sea respectively. Quarantine and cold weather checked the cholera at Staten Island, but it spread from New Orleans up the Mississippi Valley, and New York was invaded later. The fatal cases, 611 in number, during this epidemic in Boston were

proved to be remarkably confined to the crowded dirty parts of the city. The cholera hospital was at Fort Hill.

Toward the end of 1852 cholera again invaded Europe from the East, pursuing a very similar course to its previous one. It was during this outbreak in London in 1854 that Dr. Snow performed his now famous experiment of removing a pump handle, thereby depriving the inhabitants of Broad Street and its neighborhood at once of contaminated drinking water and of further disease. In 1853 and 1854 the United States and the West Indies were visited. The next general epidemic in Europe and this country was in 1865–1866, during the Austro-Prussian war. In this year cholera was particularly severe in London at the East End, a portion of the city supplied by a water company whose reservoir was little better than a sewage receptacle.

In the autumn of 1865 cholera arrived in New York but did not spread, and in the spring of 1866 it was brought both to Halifax and New York. During this epidemic St. Louis was an especial sufferer, having 3500 deaths in a population of 200,000. Boston again escaped with a very light visitation. In the last epidemic of 1873–1874 cholera visited this country before it appeared in Paris. It was first brought to New Orleans by an infected Bremen barque; many cases, however, were early imported directly through New York on non-infected vessels, the disease being subsequently developed at various points from the infected personal effects of emigrants when unpacked at their final destination.

The outbreak in Egypt last year was preliminary to that in France this year, and its details are sufficiently recent to be remembered by you.

The exact origin of the present outbreak is, but ought not to be, a mystery. The medical commissioners sent by the government from Paris to investigate it declare themselves unable to discover the origin of the first case reported to have occurred, June 14th, on board the Montebello of the French navy, a vessel which had been lying in port fifteen months. They exculpate the Sarthe, a transport from Cochin China, which had been peculiarly incriminated. It is most probable, whether unacknowledged or really not known, that this or some other transport returning from the East brought the poison in clothing, if not otherwise. The port of Toulon is one of the dirtiest places in Europe, famous for typhoid fever. The weather was hot, the nature of the malady was not distinctly acknowledged for at least ten days, and the epidemic was started, Marseilles, another very dirty city, being presently attacked.

The subsequent occurrences in Spain and Italy, the most quarantined countries in Europe, are still fresh in the minds of all of you, and I need not recapitulate them. In the three countries at least sixteen thousand victims have fallen this summer since June, of whom nearly two thirds were Italians and about six thousand five hundred Neapolitans.

All past experience leads to the belief that the present epidemic will sooner or later visit a much wider extent of the commercial world. Such countries as Germany, England, and our own, it may be said, were never so little favorable to its reception, but there is still in all of them food enough for the poison to feed upon, and on the other hand the more rapid the methods of travel and interchange of commodities the quicker the progress of such pests. A low temperature, though inimical to is by no means preventive of cholera, as shown at Orenboorg and Moscow, where, other conditions being favorable, it progressed under temperatures of −22° F. and −4° F. respectively. We may be invaded from Canada as in 1832, from New Orleans or some other Southern port as in 1848 and 1873, from New York as in 1866 and 1873. The federal authorities of the State and Treasury Departments, the State Boards of Health and city boards — at least at ports on the Northern Atlantic sea-coast — are awake to the possibilities of the situation. Public authorities, however, must be seconded by individual effort.

From this brief review of the history of cholera since the existence of accurate records, and of its course in the Western Hemisphere since its first appearance in Europe in 1829–1830, one learns two facts upon which epidemiologists are pretty well agreed: (1.) That cholera is constantly present in some part of India, where it has its periods of recrudescence, which precede the European outbreaks. (2.) That Europe is, as a rule, invaded along the lines of travel; the first epidemic followed the course of the caravans to Orenboorg in Central Russia, the last the line of the steamers up the Red Sea to Alexandria and the Mediterranean ports in Southern France.

Being agreed upon these points, the question naturally presenting itself is, Why India and the province of Bengal in India should be the home and breeding ground of cholera. And the answer is to be found in the very character of the Ganges Delta, in its climate, soil, water-courses, and consequent habits of immense neighboring populations. This is as fair an explanation as one gives for the existence of the Negro in Africa, the Mongolian in Asia, the Caucasian in Europe. In neither case need we be required to account for the appearance of the primordial representative.

The characteristics of the Ganges Delta have been often described, but I will give them to you in the words of the now famous Dr. Koch,[1] who has been a recent visitor and went to study cholera: —

"On the map of the province of Bengal you will see the Delta of the Ganges, which is bordered on the west by the river Hooghly, an arm of the Ganges, and on the east by the Brahmapootra.

"The cholera prevails continuously in the whole of this region, and on the banks of the Ganges as far up as Benares. The upper part of the Delta is not thickly set with villages, whilst the base of the triangle seems entirely uninhabited. This uninhabited district, called Sunderbunds, comprises an area of 7500 English square miles, and is separated from the thickly populated northern portion of the Delta by an extremely sharp line. Here the large rivers, Ganges and Brahmapootra, break up into a net-work of streams, in which, at the tides, the sea-water, mixing with the river-water, flows backwards and forwards, completely flooding wide tracts of the Sunderbunds at high tide.

"A luxuriant vegetation and an abundant variety of animal life have developed in this uninhabited district, a district which is not only unapproachable for man owing to the inundations and numerous tigers to be found here, but is chiefly avoided owing to the pernicious fevers which attack anybody who stops there for only a very short time. One can easily imagine what quantities of vegetable and animal matter are exposed to putrefaction in the boggy district of the Sunderbunds, and that an opportunity, scarcely to be found in any

[1] Extract from an Address before the Imperial Board of Health, Berlin. Translation in Brit. Med. Journal, September 6, 1884.

other place in the world, is offered here for the development of micro-organisms. In this respect the boundary between the inhabited and uninhabited part of the Delta is especially favorable, where the refuse from an exceptionally thickly populated country is floated down by the small streams, and mixes with the brackish water of the Sunderbunds that flows backwards and forwards, and is already saturated with putrefied matter. Under peculiar circumstances a thoroughly special fauna and flora of micro-organisms must develop here, to which in all probability the comma bacillus belongs. For everything points to the supposition that cholera derives its origin from this frontier territory. All the greater epidemics commence with an increase of cholera in the south of Bengal. Jessore, from which place the first news about the epidemic of 1817 came, lies on the borders of the Sunderbunds, and Calcutta, which is now the constant habitat of cholera, is connected with the neighboring Sunderbunds by a boggy and scantily inhabited tract of land.

"But further, the comma bacillus finds, in the districts adjoining the supposed habitat, the most favorable conditions that can be imagined for obtaining a footing and transferring itself from one man to another. For lower Bengal is a perfectly flat country, only very slightly raised above the level of the sea, and during the tropical rains almost the whole extent of it is under water. Hence everybody who settles there must, in order to protect himself from these annual inundations, build his hut on raised ground. This kind of building is seen in all the villages of the Delta, even in Calcutta itself, especially in the immediate neighborhood and in the suburbs of Calcutta, which more or less bear the character of villages. Every house or group of houses stands on a flat, rising ground, which has been made by taking the earth from a spot near where the hut is built in order to raise the ground on which the house stands. The excavation thus made becomes filled with water and forms a so-called tank.

"Every hut or group of huts must, therefore, have a tank, more or less large, and the number of these tanks is accordingly very great. The town of Calcutta alone had, till a short time ago, about eight hundred tanks, although a large number of them had been filled up for sanitary reasons. In the suburbs of Calcutta there are, besides, more than a thousand tanks still existing. I have already mentioned the part that the tanks play in the household of the Indian population, and how adapted they are for spreading the cholera. . . .

"In the interior of the town of Calcutta, amongst massive houses and villas looking like palaces, groups of huts, crowded together and resembling villages, are to be found, exclusively inhabited by natives. These villages in the interior of the town are called bustees. The huts of a bustee possess no drains, sewerage, or anything of this kind. All the dirt is collected between the houses, and, owing to the narrow mode of building, can only be removed in a very incomplete manner; and, finally, reaches the tanks directly, or is brought thither by the rain; so that the tanks become the natural places of collection for all liquid filth. . . .

"In India, also, the spread of cholera depends upon the intercourse of human beings, and is chiefly caused by the pilgrimages, which have developed in quite an unusual manner in India. We can scarcely form an idea how widely diffused these pilgrimages are in India. In order to give you an example I will only cite the two chief places of pilgrimage, Hurdwar and Puri. These are places to which hundreds of thousands of people, sometimes more than a million, flock annually from all parts of India. The pilgrims remain there for several weeks; they are penned together in a confined space, and live in a most miserable manner. Tanks are to be found everywhere in these places also, in which thousands of people bathe; they also drink the water from these tanks. It is by no means astonishing if, under these conditions, the disease, when it does break out amongst the flocks of pilgrims, is speedily scattered over the whole of India and reaches every place."

As far as anything is known of the subject cholera epidemics have never broken out "spontaneously," as it were, outside of India, and they depend upon the intercourse of human beings for their propagation. Moreover, outside of India and Cochin China their tendency is always to die out after a comparatively short space of time. These points are to-day fixed and settled, and constitute a great gain in knowledge over a very recent time when the partisans of many hypotheses, or notions rather, as to the cause and progress of cholera were in constant collision with each other and with facts. According to one of the earlier suppostions "the disease advanced as a great morbific wave rolling slowly and steadily westward, enveloping place after place, and country after country, with a certain steady progress at nearly regular intervals; next it was supposed, as it often seemed to come with ships, and the commerce of the world was then carried on by sailing vessels, that it was blown about by the same winds which brought the ships; but as land-travelers brought the pestilence in spite of and in the teeth of winds it was found necessary to suppose that ships brought it in their holds and well travelers in their soiled clothes, especially in those which had been boxed up." [1]

The present position of the best authorities, which meets facts as observed, and may be accepted as correct, may be briefly stated thus: That cholera is conveyed by individuals, and its poison is contained in and is propagated by the discharges from the bowels of those infected, which finding access to drinking water, or resting upon food or upon the hands, gain entrance to the digestive tract of others. It is not certain that in a heavily charged atmosphere the poison may not be swallowed with the air, but the infection must always take place through the alimentary canal, and in this very limited sense alone can cholera be spoken of as "contagious," thus probably resembling typhoid fever. In other words, an individual who could avoid swallowing the poison might safely associate with cholera patients, and the digestive functions being quite healthy he would probably escape even if swallowing a moderate dose.

I purposely abstain from going into the minute pathology of cholera, from calling the poison a germ, much less a microbe, and still less a bacillus or spirillum. This whole department of minute pathology is, it seems to me, too technical and still too unsettled for our purposes this evening. Its introduction would, moreover, make a long story much longer.

We will now turn to the second part of the subject of the evening, the progress and propagation of cholera, which leads us to the measures to be adopted for its

[1] Congressional Report, 1874.

prevention — so long and unfortunately known as quarantine. A review of the history of cholera and a statement of its ætiology and mode of propagation suggest immediately its mode of progress and the means of prevention. The flux of the bowel contains the poison, moist filth nourishes and breeds it, the deranged alimentary canal invites and entertains it anew.

Hence to prevent the entrance of the disease to a place or country we require cleanliness of person and purlieus, a plentiful and pure water supply, perfect drainage, and wholesome living. To oppose its spread, once being in, we demand occasional isolation of the sick, and constant destruction or disinfection of contaminated discharges and effects.

Just in proportion as communities are conscious of shortcomings in sanitation, in water supplies, in drainage, and are too poor or too lazy to reform such, they may and will call for a quarantine whose rigidity shall be in direct ratio to these deficiencies. They may thus deceive but will not protect themselves. The worthlessness of a perfunctory quarantine of a fixed number of days — whether of five or of forty — for every vessel if on the sea-board, or for every individual if in the interior, has been proved over and over again, and never more forcibly than in the late invasions of Italy and Spain. If declared only against infected ports or localities it is insufficient, if against every outside place it is impossible. The enormous and intimate commerce of the day abhors such obstructions, and ingenious human nature evades them. A French sanitarian well expressed this in his reply when asked why the inhabitants of Toulon were permitted to infect the outside country: "If we had built a wall around the city the people would have burrowed under it." A *cordon sanitaire* is always foolish and often wicked. There are also especial difficulties in excluding and controlling such a disease at a town like Toulon, with its population. What might be comparatively simple in Boston, or even in New York, would be impossible there. The French Minister of the Interior gave expression to these perplexities in saying, that it would be easier to revise the Constitution than to renovate Toulon.

The period of incubation of cholera is believed to be over twelve hours and under five days. On an average two to three days. The life of the poison outside the bowel, even when favored by moisture, is believed to be rather short — probably under thirty days. Based on these observations the best aid to sanitary supervision at home for the exclusion of cholera is notification from foreign ports or places by competent authorities of the departure of infected vessels or individuals, and inspection upon arrival by trained sanitary officers with a certain latitude of action. More reliance being placed upon the judgment of the individual official than upon the rigid phraseology of a State or national proclamation.

A conference of State Boards of Health met at St. Louis last week and adopted a series of recommendations for "practical work required for the prevention of cholera in this country," to be urged upon the government at Washington, upon State authorities, and upon individual citizens, a copy of which I hold in my hand.

The representatives of interior countries and of those on the sea-board necessarily take somewhat different views of the value of quarantine and of the relative reliance to be placed upon external and internal quarantine. There appears in the recommendations adopted a desire to harmonize conflicting views, and to secure the coöperation of all concerned.

There will always be the inclination to place the responsibility for the introduction of a disastrous epidemic at some remote point, and upon some one else's shortcomings. In our own country States situated in the Mississippi Valley feel that New Orleans should protect them from and not furnish them with yellow fever. Illinois is, naturally, aggrieved if New York and Boston send unvaccinated immigrants, with smallpox contagion among them, by through trains into her borders. In some degree in these matters there is cause for complaint, in some degree fear and feeling and an unwillingness to put things to rights at home have at times usurped the place of reason and judgment.

If I have been in any way obscure or unsatisfactory in what I have said let me hope that you will in some degree at least attribute it to the want of proportion between the subject and the time of the Society which I felt at liberty to allow myself.

And in conclusion let me again remind you that a good water supply, good drainage, wholesome living, a tranquil spirit, these are the true safeguards against cholera preëminently, as against sundry other epidemic disorders in a lesser degree. These are the agents dreaded by epidemic poisons even if really residing in microbes with pathological tendencies, and whether presenting themselves in the bacillar or the spirillar forms, or as hybrids with comma-like extremities.

Original Articles.

THE PREPARATION OF LIEBIG'S FOOD.[1]

BY E. T. WILLIAMS, M. D.

THE earliest announcement of Liebig's method of preparing infants' food was received with the warmest enthusiasm by the profession and the public. The idea of using malt as an artificial digestive for starch was certainly a brilliant one, and seemed to promise an infallible cure for every form of starchy dyspepsia both in children and adults. It must be confessed, however, that time and experience have not fully borne out these expectations. The results obtained from its use were found to vary. Many gave it up in disappointment. Others altered and tried to improve it. In fact it has never been generally adopted. Notwithstanding all this its benefits in many cases are decided, so that we shall find, I think, that the trouble lies not in the thing itself, or the principle on which it rests, but in a faulty method of preparing it.

The commonest objection to Liebig's original formula is that it is too complicated. I consider this objection entirely frivolous. It is no more complicated than making bread or pastry, or any other of the common operations of cookery. I give here in substance Liebig's own directions, though I shall take the liberty of simplifying a little both the language and the process: —

Mix half an ounce of wheat flour with five ounces of milk in a saucepan, taking care not to lump it. Heat it to boiling, stirring carefully; let it boil from three to four minutes, and remove from the fire. Now mix half an ounce of malt flour, one ounce of water,

[1] Read before the Norfolk District Medical Society, October 28, 1884.

and seven and a quarter grains of bicarbonate of potash, and add it to the milk porridge, stirring steadily. This has the effect of thinning it out and making it sweet. Now cover up the vessel and let it stand half an hour where it will keep warm but not boil. Finally set it back on the fire, let it boil up once, and strain it through a fine hair sieve to remove the bran.

The temperature at which the mixture should be kept after the addition of the malt should be about 150° F. Be sure that the porridge has entirely ceased boiling before the malt is added. The food when done should be quite thin and sweet.

It will be seen that there is nothing difficult about this process. No one can say so who has tried it, however hard it may look on paper. Every physician ought to be able to teach the mother, nurse, or cook how to make it.

It may be remembered, as Liebig remarks, to save the trouble of weighing, that a heaping tablespoonful of wheat flour weighs just about half an ounce. One half of a heaping tablespoonful of malt flour weighs the same. The liquids may be measured in a tablespoon or wine-glass. The former contains one half ounce, the latter two ounces of liquid. The potash should be put up in powders by the apothecary. Most cooks could "pinch" it up pretty accurately with the thumb and finger.

On the subject of malt, Liebig's directions are as follows: —

"Barley malt can be readily bought of any brewer. . . . A common coffee-mill answers for the preparation of the malt flour. It must be separated from the bran by passing it through a coarse hair sieve."

Such is the original formula, simplified a little, from Liebig. In many cases it answers every purpose perfectly well. There is, however, one serious objection to it. The food sometimes loosens the bowels. Such is my own experience; such is the general testimony of those who have used it. The trouble seems to be this: the coffee-mill grinds up too much bran, which gives a laxative quality to the food. I do not know what sort of a mill Liebig used, or what kind is most common in Germany, but the American mill (and I have tried this experiment many times) grinds husk and grain together, so that it is impossible to purify it effectually by sifting, thus rendering the food quite unfit for dyspeptic children, or those subject to a loose or washy state of the bowels. Whoever will try the experiment of grinding malt in this way and examine the flour (no matter how carefully sifted) under the microscope will find it quite full of angular pieces of husk, fully sufficient to explain its irritating action on the intestinal lining. I believe this to be the radical defect of the Liebig process, and the grand reason why the food has never come into more extended use.

It was long since discovered by practical men that the food was uncertain in its action, and apt to disagree. This led many to look for a better way of making it.

One of the best plans is to use a prepared malt extract in place of the malt flour. A liquid malt extract is now officinal in the United States, and is prepared by dissolving out the soluble part of the malt in water, and evaporating down to a syrupy consistence. This, of course, eliminates completely the insoluble husks. There are several brands of malt extract in the market, of which Trommer's is perhaps the best known. It makes excellent Liebig's food, and, as far as my experience goes, is entirely devoid of laxative properties. Keasby and Mattison's extract, and Reed and Carnrick's "Maltine" (in spite of its objectionable name), seem to answer equally well.

I have tried several forms of "dry" extract of malt, Horlick's, Thayer's, and Tilden's. The samples tested were purchased in the open market and were apparently fresh. I am sorry to say that their diastatic action was extremely slight. Not one of them could turn its own weight of starch into sugar. This is readily tested by boiling a little flour or starch with water in a test tube or saucepan till it thickens up, then removing from the fire till it stops boiling, then stirring in the malt or malt extract previously wetted. If diastase in proper amount is present the starch paste soon thins out and becomes quite fluid, from the change of the starch into gum (dextrine) and sugar. The same change takes place in making Liebig's food. It is then sweet to the taste, and continues to grow more so the longer it is heated, until all the dextrine is changed into glucose. When tested with iodine it shows an entire absence of starch. Under these tests the dry malt extracts which I examined showed themselves to be of little value. The action of the liquid extracts was good, though not so good as fresh malt. I attribute this superiority of the liquid extracts to the syrup, which, as I fancy, acts as a preservative to the diastase.

I ought here to mention that the experiments above quoted were made during the last season at the Sea-Shore Home with the assistance of the house physician, Mr. Charles W. Townsend, of the Harvard Medical School. We tried most of them separately and together, so that I feel able to state the results with confidence.

It is evident, therefore, that a liquid malt extract like that of the Pharmacopœia may be satisfactorily substituted for malt flour in the preparation of Liebig's food. Being free from insoluble matter it may be relied on not to scour or purge. The only objection is the high cost of the extracts now in the market. The Trommer extract sells for one dollar a pint; Keasby and Mattison's the same; the "Maltine" bottle is larger, containing about a pint and a half; the price is the same. Malt itself is worth from five to ten cents a pound.

The notion of a manufactured Liebig's food prepared to hand and ready for use was a natural conception, and has much in its favor. This does away with the trouble of cooking, and secures a perfectly uniform product. One of Liebig's sons, with the "help and approval" of his father, as he states,[1] is or was concerned in the manufacture of such an article under the name of an extract of Liebig's food. Similar preparations under less honest names have been sold in England and America. They are made or should be made by digesting malt and water in the form of a "mash," as brewers do, till the starch changes to glucose, and then evaporating to dryness in a vacuum. They are nothing more than Liebig's food ready made and evaporated down for convenience of keeping and dispensing. The popular Mellin's and Horlick's foods are supposed to be articles of this sort. They consist mainly of grape sugar with the nitrogenous and mineral elements of grain. The objections to their use are the misleading names under which they are sold, and their high

[1] Vide J. v. Liebig, Suppe für Säuglinge, dritte Auflage, Seite 37. Braunschweig. Vieweg und Sohn. 1877.

price. A half-pound bottle of Mellin's food costs seventy-five cents. A one-pound can of Horlick's food sells for the same price. It is not easy to understand why these articles should cost much more than common sugar. Malt and other grains cost but a few cents a pound. The mashing process is the same as in making beer. The evaporation *in vacuo*, the only expensive part of the operation, is similarly employed in making sugar. Making all allowance for the outlay on machinery, the expenses of selling and advertising, and for loss by spoiling, it is clear that the profits on these foods must be enormously large. On the other hand, it is fair to say that they are good foods as far as nutritive purposes go, and suit children extremely well. It is to be hoped that greater competition and a more enlightened public opinion may bring the prices within reasonable limits. The same hope may be expressed with regard to the malt extracts. At present prices these preparations are entirely beyond the means of the poor people, who form the bulk of our patients.

This drives us back again to a closer consideration of the original formula. Its cheapness and ready availability make it by all means the most desirable method if we can only find a way to remedy its one serious defect, the presence of the indigestible husks.

I believe I have hit on a way to do this in an improved method of preparing the malt flour. Instead of grinding the malt in a coffee-mill I have adopted the plan of crushing or braying it with a mortar and pestle. This breaks up the kernel but does not, unless carried too far, grind and tear the husk. It is highly important to use the pestle lightly, not to put but a small quantity in the mortar at once, and not to pound or grind too long, as this breaks up the husk too much. The meal should then be "bolted" or sifted through a fine wire or hair sieve. This makes a fairly good imitation of the miller's way of grinding. The fine malt flour thus obtained should not exceed in bulk more than half the mass of separated husks and bran. Examined under the microscope the proportion of seed coats and hairs is found to be far less than in that made by the coffee-mill process. This fact was carefully verified by Mr. Townsend, who was good enough to make the examination for me, and who showed me the slides which he had prepared. I am sorry I have not yet had the opportunity of testing the flour as fully as I should like upon sick children, as the season was nearly closed when the idea first suggested itself to my mind. Another year I intend to give it a thorough trial.

It will be objected, of course, that this is a troublesome plan. Few housewives make it much of a task to pound up sugar and spices for the making of indigestible cake and pastry. Few mothers would think it a hardship to do as much for a beloved child provided they understood exactly how to do it. It should be the duty of the physician to go down into the kitchen and instruct the household in every detail of the operation.

A few minor considerations before I close the subject.

Liebig directs the food to be made of nearly clear milk. For children within the month it ought to be at least two thirds water; from one to three months, half and half; at four and five months, two thirds milk; at six months, the full strength.

Liebig alkalizes the food with bicarbonate of potash to prevent its curdling on the stomach. In cases of diarrhœa lime-water should be substituted in the proportion of a tablespoonful, or more if necessary, to six ounces of the food.

Liebig recommends the food as a nutritious drink for adults as well as children. Its suitability for invalids and convalescents, for nursing mothers, and starchy dyspeptics goes without saying. Liebig recommends it in coffee in the place of cream. I have found it very good in chocolate. With coffee especially, in the style of *café au lait*, I have found it a capital breakfast drink. I think that both coffee and chocolate *à la Liebig*, if they could be made fashionable, would make a most useful addition to our dietary.

I should say, in conclusion, that malt may be purchased of any grain dealer. As it spoils very quickly it should be bought only in the smallest quantities, and closely kept in a glass-stoppered bottle or tin canister. Only enough for a few days' use should be ground at a time.

UNILATERAL ATROPHY.

BY H. L. BURRELL, M. D.

A DECIDED inequality in the two halves of the body is extremely rare; slight inequalities are the rule rather than the exception.

A decided inequality in the halves of the body is considered a deformity, and the cases which are presented in this paper are looked upon in the light of deformity, passing as they do the boundary line of normal asymmetry into the interesting field of pathology. On looking at these photographs it is at once recognized that we have before us a strange condition. A female child of nine years, each half of its body perfectly developed, but the left two or three years behind the right half in its stage of development. The face is not shown, at the mother's request, it being practically symmetrical; the whole left half of the trunk, however, is markedly diminished in size; this is especially marked in comparing the clavicles and the halves of the pelvis. The circumference and length of the arm, fore-arm, thigh, leg, and foot of the left side are less than the right, and one is particularly struck with the posture the child assumes, it being very suggestive of hip trouble; a glance, however, at the posterior view of the child shows neither flattening of the nates or obliteration of the normal sulci, but shows in a very clear manner the compensatory obliquity that takes place in the pelvis and the resulting spinal curve.

Of much interest in connection with these deformities is a consideration of the fallacies surrounding measurements of the lower limbs and the normal asymmetry of the human form.

Sculptors, artists, hatters, tailors and shoemakers have always been familiar with this fact, and it is surprising that surgeons should not have more generally appreciated this source of fallacy in their measurements of the extremities. Hunt,[2] of Philadelphia, claims to be the first to have suggested that "bilateral symmetry as to length is exceptional," a fact of great importance in suits of malpractice.

W. C. Cox called attention[3] "to the difference in

[1] Read before the Surgical Section of the Suffolk District Medical Society, March 7, 1884.
[2] Am. Jour. Med. Sc., January, 1879.
[3] Am. Jour. Med. Sc., 1875, vol. lxix., p. 438.

measurements of the opposite sides of persons never diseased or injured." Out of sixty-two persons examined only six were found with extremities of the same length.

Dr. Wight[1] gives the measurements of sixty persons, and concludes that one person in every five has limbs of the same length. Dr. Morton in the Pennsylvania Hospital Reports[2] states that he has examined the length of the lower limbs in 513 boys from eight to eighteen years old. In 272 there was inequality.

Then come statistics which seem to settle the question. Roberts[3] found asymmetry the rule in femora and tibiæ of eight skeletons. Dr. Thomas Dwight[4] reports the measurements in eleven skeletons, and found only five in which the femora were equal; and J. G. Garson reports[5] the measurements of seventy

skeletons, and found asymmetry in ninety per cent. During the last year three cases of unilateral atrophy have presented themselves at the Children's Hospital Out-patient's Department, and in looking up the literature of the subject it is found that only a few cases are recorded.

Paul Broca[6] reports a boy aged eleven as appearing "as if the two halves of the body were different sized persons joined together."

In 1863 Mons. L. Ollier recorded[7] a number of experiments in animals by tying the various arteries and by section of the nerves supplying the different extremities. No satisfactory conclusion can be drawn from these experiments, and one can only surmise that some disturbance of the trophic centres exists as a factor in the causation of the atrophy.

A. Stadfeldt[8] and Jacobi[9] consider the causation anterior to the sixth month of fœtal life, and Jacobi has a theory that the condition is of pre-placental origin.

Mr. Howden gives a case[10] of an insane woman, aged thirty, who had atrophy of the right hemisphere of the cerebrum and left side of the cerebellum, with atrophy of the left side of the body.

A case of unilateral atrophy was exhibited before the Clinical Society of London of left-sided atrophy with athetosis, in a woman aged twenty-two, by Dr. T. Taylor.[11] Another case of marked left-sided atrophy was shown to the Société Anatomique by Henry C. Beyer.[12]

Two other cases are recorded: one of congenital unilateral atrophy by Sumner Pixley,[13] the other a case of semi-facial atrophy by Schiek.[14]

The first case observed was that of a bright girl, M. B., aged nine, born in Canada, and living in South Boston. The child had always been rather delicate, but no difference was noticed in the development of the halves of the body until the child began to walk. She applies at the out-patient's department on account of limping. On removing the clothing one notices that the whole of the upper and lower extremity of the left side are smaller than the right. The left arm is one inch shorter than the right; the left thigh one and a half inches shorter; the left leg and left foot are each one half inch shorter than their fellow.

No difference in the development of the halves of the face is apparent.

The left fore-arm is a quarter inch smaller than the right; the left thigh a half inch, and the left leg a quarter inch less than the right.

Second case. J. R. M., aged four, born in Boston. He is a ruddy, sturdy little boy, who "has always been well." The mother noticed a slight limp when he began to walk. The right thigh and leg together are a half inch shorter than the left; the thigh is a half inch, the leg a quarter inch, smaller than the left. The child is left handed, and left arm and fore-arm are perhaps slightly larger than the right. The right foot measures a quarter of an inch in length.

Each lower extremity is perfectly developed up to its standard, but on comparison one notices that the right is decidedly the smaller of the two. The head and upper extremity are apparently nearly equally developed.

The last case is a female child, S. M., aged two years and three months, who lives in Waltham. The mother states that the child has always been strong and healthy, but when eighteen months old began to walk,

and from the first with a limp. There has never been any loss of power in the limb. The child is very bright and well nourished, but walks with a decided limp of left leg. When the child stands erect, resting both feet upon the ground, the right knee is bent slightly forward. When the right leg is perfectly straight and pelvis horizontal the left leg does not fully reach the ground. Measurements give three quarters of an inch shortening in left leg, three eighths of an inch of the shortening being in the thigh. There is half an inch of atrophy of the left thigh, and a quarter of an inch of the leg. The left foot is decidedly smaller than the right (seemingly more marked than the tracing would show). By measurement in its longest diameter the left foot is a quarter of an inch less than its fellow. There is beginning valgus of the right foot. The face and upper extremities were closely examined, and were found to be slightly smaller than the unaffected side.

The treatment in all these cases has been an extra sole on the shoe to horizontallize the pelvis.

The writer has not considered measurements under a quarter of an inch, believing that the finding of bony prominences covered with soft parts as a point of departure in making any given measurement allows a latitude of at least an eighth of an inch in the hands of the most accurate observers; and pertinent to this question is an apt remark made by the late Dr. T. B. Curtis, who believed "that to find the anterior superior spinous process of the ilium in a living subject was as difficult as to precisely determine the top of a hill."

As far as the parents' observations go the atrophy is not progressive, and although these cases are not termed congenital there can be but little doubt that this is not an acquired deformity.[1] Whether the disproportion has been caused by an excessive growth on the one side or a retarded growth on the other is not easy to decide. Beyond this I cannot venture into the region of speculation as to cause.

In considering these cases as a class one finds that the mother's labors have been perfectly normal; that there is no difference in the pulse, temperature, consistency, tendon reflex or ankle clonus of the affected side; that the children are in good health; that they have never received any injury; that they simply apply for relief to the lameness; that the mother first noticed the trouble when the child began to walk; and that there has never been any loss of power in the affected limbs. The practical importance of these cases rests upon a recognition of the deformity, its differential diagnosis from various diseases having as a symptom lameness and atrophy of one of the limbs, and the general influence it will have in causing deviations in the spinal column, by obliquity of the pelvis. The important bearing which inequality in the length of limbs may have in producing lateral curvature is well set forth in a recent paper by Henry Ling Taylor,[2] where he reports thirty-two cases of primary crural asymmetry. The left leg was found to be longer in twenty-eight cases, the right in four. Dr. Taylor's differences in measurements are not in eighths or fourths of an inch; in sixteen cases the difference is over one half an inch, and in six it is an inch or more.

Not only may obliquity of the pelvis result from this lack of symmetry, but it is probable that in female children important changes may take place in the pelvic cavity that may interfere very seriously with parturition. Finally, in one of our cases we have a beginning valgus which is apparently compensatory, and this deformity superadded to the asymmetry would seriously interfere with the locomotion of any child.

[1] In this connection it is well to say that were the writer positive that the deformity is congenital he would prefer the term asymmetry to that of atrophy.

A FATAL CASE OF PUERPERAL CONVULSIONS PRECEDED BY EXCESSIVE EPIGASTRIC PAIN.

BY F. W. GOSS, M. D.

MARCH 1, 1884, I was called to a lady, thirty-two years of age, seven and one half months advanced in her fourth pregnancy, with the following history: —

Two years ago she had a miscarriage. Her confinements in 1876 and 1879 were, she thought, a little premature, but not otherwise abnormal. During the present pregnancy she has been quite comfortable most of the time, and appeared to be in a satisfactory condition when, six weeks ago, she called to engage me for her confinement, since which time I have not seen her until now.

At 12.30 A. M., March 1st, I found her suffering with intense pain in the epigastrium, extending through to the back. She said that for two days past she had had some discomfort in these parts, which she attributed to having taken cold in going into town in the horse cars three days ago. She ate a good dinner at six o'clock last evening, and was quite comfortable till within an hour, when the severe pain above mentioned came on. She has no headache, nor has she suffered from it, excepting occasionally, and no more than for years. No trouble with eyesight. Slight œdema of feet; none elsewhere. Cardiac and pulmonary sounds normal. No signs of labor. She thinks her urine may have been more abundant than usual for a few days past.

As stated above, I found her suffering from agonizing pain in the epigastrium and the opposite part of the back. She was restless, cold, pulse 76. Had a load at stomach, but had not vomited.

At one A. M. she vomited, evidently her dinner undigested. She felt easier for a few minutes, but the pain soon returned. Under the administration of morphia by the mouth and subcutaneously, and the application of chloroform liniment, she gradually became more comfortable, and at 4.30 A. M. I left her sleeping. I requested a specimen of urine as soon as any should be passed.

7.30 A. M. Has slept two hours, and is much refreshed. Has been thirsty, and has drunk a large amount of ice-water, which she is now vomiting. Mind perfectly clear. Has considerable headache, which may be due to opiates. Pulse normal. Skin warm. No urine has yet been passed. I left with the promise to call again at noon.

She vomited twice after this, and with some difficulty passed several ounces of dark-colored urine. At 9.30 A. M. her husband lay down beside her on the bed to sleep. At 10.30 he was awakened by his wife, who said she felt terribly, and believed she was dying. She immediately had a severe convulsion, and never recovered consciousness. The messenger not finding me at home, a professional friend promptly responded to the summons. He found no indication of labor, and at

once proceeded to deliver the patient by manual dilatation of the os uteri. When I reached the scene, soon after eleven o'clock, she had been delivered of a female, still-born child, and was rapidly sinking. She died at 11.30 A. M.

A subsequent examination of the specimen of urine which had been saved showed a specific gravity of 1030. It was dark in color. Under the microscope no blood was found, but there were an immense number of granular casts, and a few fatty and partially hyaline ones.

The object of this report is to call attention to a premonitory symptom of puerperal convulsions not often referred to. In looking through a large number of obstetrical works contained in the Boston Medical Library I fail to find but infrequent mention of the symptom in question. Braun, Ingleby, and Winckel translated by Chadwick, incidentally mention pain in the epigastric region as among the phenomena foreboding convulsions. Thomas Denman, to whom Churchill refers, says: "Convulsions preceded by violent pain or cramp at the stomach are usually more dangerous than those which are preceded by affections of the brain only." But Chaussier, as quoted by Leishman,[1] gives the most distinct reference to the symptom under discussion as follows: "There are three symptoms [of puerperal eclampsia] which, as premonitory indications, deserve special attention: these are cephalalgia, derangements of vision, and epigastric pain. . . . The third of the premonitory symptoms of Chaussier, epigastric pain, is of less frequent occurrence than the other two. The suffering is described as being extremely severe, lasting often for hours; and, when it is of unusual severity, it is said to be an almost certain precursor of a convulsive attack."

In view of these statements, and of the case here reported, ought we not, when called to a pregnant woman suffering from severe epigastric pain not clearly arising from indigestion, to bear in mind the possibility that she is threatened with convulsions of the gravest character?

PROGRESS IN DERMATOLOGY.

BY GEORGE H. TILDEN, M. D.

CUTANEOUS PIGMENT.

In order to arrive at correct conclusions with regard to the formation and distribution of the cutaneous pigment Dr. S. Ehrmann[2] has made study of the skins of frogs and salamanders. From such investigations it is evident that the formation of pigment takes place only in the direct neighborhood of the blood-vessels, and that a necessary factor in the process is cell activity. Pigment is never manufactured in the epidermis, but is transferred to the latter from the corium, where it takes its origin, by means of currents of protoplasm. Demonstration of these facts is best given by the study of frogs. In these animals, namely, there exists under the epidermis, in the upper part of the corium, a continuous layer of movable and pigmented connective-tissue cells. Circumscribed collections of these cells are occasionally met with, however, which do not contain pigment, in which case the region of epidermis situated immediately over these cells, is pigmented to a much greater degree than the surrounding epidermis. It is manifest that the pigment has been transferred from these localized regions of the corium to the overlying epidermis, while the connective-tissue cells of the corium in which the pigment is manufactured, remain in place. The coloring matter of the epidermis is contained in the cells of the deeper layers of the rete Malpighii, which are possessed of amœboid prolongations, and also in peculiarly branched and movable cells from which extend processes between the epidermal cells. Pigment is taken up from the deepest layer of epidermal cells, and is further transmitted, partly by means of the bridges of substance which connect the epidermal cells, and also in part by the above mentioned branched amœboid cells. This transportation of pigment is carried on by currents of protoplasm from one cell to another, and is not due to the currents of fluid in the tissues. The above facts with regard to the pigment in the skins of amphibians, where the conditions are of the simplest, hold true also, with slight modifications, of the movements of pigment in the human skin and hair. With regard to the latter, the cells which form the pigment are situated in the hair papilla, in a structure, namely, which belongs to the corium. In the root of the hair are to be seen branched cells, which send their prolongations between the epidermal cells of the hair, and which are in connection with the latter. These cells take up the pigment from the hair papilla, and transmit the same to the upper portions of the hair, and the common cause of grayness of the hair is the destruction and absence of these cells. Pigment cells are contained not only in the matrix and papilla of the hair, but are also situated between the two, these intermediate cells being connected by their prolongations both with the pigment cells in the hair papilla and with the similar cells in the hair itself. Even in the case of entirely white hairs the hair papillæ always contain pigmented cells, a single exception to this rule being furnished by the condition of senile atrophy of the skin. It may, therefore, happen that in spite of uninterrupted production of pigment in the corium the hair remains white because the cells do not exist, which transfer the pigment from its seat of manufacture to the hair itself. In the case of a man, twenty-eight years of age, who was possessed of numerous white hairs, the author found that the uncolored hairs, although otherwise normal, contained none of these pigment-transferring cells, while in the colored hairs belonging to the same individual these cells were invariably present. In another man, twenty-six years of age, there coexisted with a like condition of things in the hair a well-marked and progressive vitiligo, situated mainly upon the hands and face, a connection which well illustrates the near relationship between the two processes, cavities being merely a vitiligo which is confined to the hair. In pigmented hairs, pigment cells are found in the root of the hair as well as in the hair papilla, but against the assumption that such cells wander from one position to the other is the fact that in the case of gray hairs, although typical pigment cells are present in the hair papilla, none are to be found in the root of the hair, there being at the same time no evident reason why these cells should not wander from the hair papilla into the roots of the hairs, since the tissues are normal in appearance, and in their behavior with respect to artificial coloring matters and chemical reagents the same as in pigmented hairs.

[1] Leishman's System of Midwifery, pages 640-641. Philadelphia, 1873.

[2] Allgemeine Wiener med. Zeitung, No. 29, 1884.

The formation and disappearance of pigment in the skin follows the same general laws as in the hair. Congenital albinism or deficiency of pigment in all the tissues of the body is not to be classed with the above instances of partial want of pigment, inasmuch as it is here not a question of insufficient transfer of pigment, but rather of a total and universal lack of cells, whose function it is to manufacture pigment. The difference between vitiligo and albinism is the same as that between spotted animals and albinos of the same species. In vitiligo, pigment is formed in the corium, but is not transferred to the epidermis because the peculiar pigment transferring cells are, for some reason or other, wanting in the epidermis. In spotted animals the process is analogous, and may be regarded as a physiological vitiligo. The pigment which is formed in the corium in cases of vitiligo does not remain there, but is in a great measure reabsorbed, while a certain portion of it is transferred to the immediate vicinity, and is taken up by the neighboring cells in the epidermis, and it is for this reason that the vicinity of a patch of vitiligo is more strongly pigmented than normal. By reason of the facts that in regions affected by vitiligo the pigment-transferring cells in the epidermal layers of the skin are wanting, and that the epidermal structures of themselves do not form pigment, the hairs which are situated in the diseased portions of skin are also devoid of pigment. If a spot of vitiligo be subjected to the action of a vesicant, there ensues pigmentation, which, however, entirely disappears in a short time. In such case the cells of the corium, being stimulated thereto by the action of the vesicant, form pigment, which is in a short time reabsorbed, since the cells of the corium, although competent to produce pigment, are not capable of retaining it, and since the cells which should transfer it from the corium to the epidermis are wanting. If, on the other hand, a normal region of skin is irritated by means of a blister oftentimes this portion of skin may be recognized long afterwards by its increased amount of pigmentation, for in this instance the cells are present which transfer pigment to the epidermis, where it is preserved for a long time. The cause of the destruction or absence of these peculiar pigment-carrying cells in cases of vitiligo and in canities is entirely unknown.

Dr. Gustav Riehl[1] also publishes a contribution to the study of the pigment in human hair. The numerous variations in the color of human hair are essentially dependent upon the differing amounts of pigment contained in the horny substance of the hair, other conditions, such as the individual color of the epidermal cells of the hair, the quantity of fatty sebaceous matter upon its surface, and the amount of air contained within the hair, being of comparative unimportance in this connection. Cross sections through the hair papilla at its point of greatest circumference show that there are present, in the tissues of the papilla, irregularly-shaped cells containing granular and deeply-pigmented protoplasm, and without well-marked nuclei. Some of these cells are round, others spindle shaped, while many are possessed of exceedingly irregular outline. They also differ from one another in the quantity of coloring matter they contain, and occasionally in the same cell, one end may be seen to be more strongly pigmented than the other. These pigment cells are also situated directly beneath the matrix of the hair, being in contact with the same, and in thin sections it may be demonstrated that filiform, bulbous, or wedge-shaped prolongations of these pigment cells are inserted between the cells which compose the root of the hair. Not unfrequently these processes or branches are as long as the combined diameters of three or four cells, and extend beyond the cells of the matrix of the hair to those situated immediately above. Occasionally pigment cells are met with whose body is of very small size, from which several prolongations of very irregular form and dimension insinuate themselves in the interstices between the epithelial cells. If examination of the hair be made further up, at the region, for example, in which Huxley's layer is undergoing the change into horny substance, only small fragments of these pigment cells or their prolongations, in the shape of short pigmented filaments, are to be detected between the cells of the hair, while at the same time pigment is to be seen in the protoplasm of the epithelial hair cells, the nuclei of the same being entirely wanting in pigment. The coloring matter is in the form of fine granules, which are thickly clustered about the nucleus, and but loosely and irregularly distributed throughout the rest of the cell. In the older cells of the hair the pigment is more diffused, with here and there a clump of pigment granules, the coloring matter being intimately mingled with the horny substance of the cells, which is thereby stained, as it were. The manner in which pigment is transferred from the pigment cells to the epithelial cells is shown by thin sections of hair, in which it may often be seen that the prolongations from such pigment cells are sharply defined until they reach the epithelial cells, at which point their distinctness of outline is lost, and the end which is in contact with an epithelial cell acquires a vagueness of contour which obscures its recognition. The protoplasm of the epithelial cells in the neighborhood of these prolongations of the pigment cells becomes of a uniform yellowish-brown color, and contains collections of pigment granules, which are grouped together in that portion of the cell situated nearest to the end of such prolongations, giving one the impression as if the pigment tissue had become melted and was imbibed by the epithelial cells. The process resembles that by which the lower amœboid organisms take up granules of coloring matter from the water in which they are contained. Whether the protoplasm as well as the pigment of the pigment cells is absorbed by the epithelial cells is not evident, as the author has not yet been able to detect either decolorized pigment cells or free pigment between the epithelial cells of the hair. The author concludes that the pigment of hair is always contained in the cells, being situated in the wandering pigment cells of the papilla and root of the hair, and, in other regions of the hair, in the epithelial cells themselves.

DERMATOSIS DIABETICA.

Kaposi[2] reports a rare case of "gangrena diabetica bullosa serpiginosa" occurring in a woman fifty-one years of age. About one month before she was seen by Kaposi there began to show themselves upon the leg cutaneous lesions of a gangrenous nature. The initial form of the above lesions consisted in one or more blebs, tensely filled with an opaque fluid, and upon removal of the epidermal covering of these blebs it was evident that their base was formed of a yellowish white slough in the corium. Further development

[2] Wiener med. Wochenschrift, Nos. 1, 2, 3, and 4, 1884, and Medecinischer Jahrbücher, Heft 1, 1884.

of the pathological process resulted in the formation of large spots of cutaneous necrosis, in which were manifest three distinct stages of progress. The gangrenous lesions were of rounded, triangular shape, and at their convex side, in which direction the pathological process was advancing, the tissues were in a condition of dry gangrene, the skin being mummified, of a leathery consistence, and sunken somewhat below the general cutaneous level. The edge of this mummified region was not in immediate contact with sound skin, but was separated from it by a narrow and flabby fringe of discolored epidermis which had been raised from its bed by serous exudation. In the centre of the lesion the gangrene was of the moist variety, the cutaneous tissues being reduced to a greenish pulp, and on the concave side of the lesion, bordering upon the moist gangrene, were lively red and profusely suppurating granulations, the edge of which was defined by a sharply-marked line of normal skin, not elevated, and having a narrow, bluish-white border of young and advancing epidermis. The process was, therefore, one of destruction followed by repair. There were three such gangrenous lesions upon the left lower leg, the largest of which was larger than the palm of the hand, the smallest the size of a thaler. They were situated, one just below and outward from the anterior superior spine of the tibia, another at about the middle of the leg on the inner side, and the third at the middle of the leg on the anterior and outer side. Their convex edges were directed away from the anterior middle line of the limb, and upon the region of skin which was inclosed, so to speak, by the three lesions, were situated from ten to fifteen blebs, each one the size of a bean. The general surface of the skin between the blebs and around the gangrenous spots was entirely normal in appearance.

The case in question had nothing in common with the ordinary forms of gangrene of one or both lower extremities. In senile gangrene, in gangrene due to marasmus, and in death of tissue caused by embolism or thrombosis of the blood-vessels, the process begins in the toes and their neighborhood, and is preceded by a gradual or sudden lowering of the temperature of the parts and by inflammatory processes. The cessation of the circulation from some cause or another is in these cases the determining condition, and the arrest of blood supply is generally announced by inflammatory and congestive phenomena, while the necrosis which follows attacks without distinction all the tissues "en masse," the skin, muscles, tendons, and bones. The same is true of the interesting variety of gangrene due to endarteritis obliterans, which has been observed and described by Winiwarter and Billroth. Gangrene as the result of mechanical violence, chemical insult, or extremes of temperature was out of the question. The forms of cutaneous gangrene occasionally seen by the author, in connection with pityriasis rubra, chronic general eczema, severe psoriasis, and pemphigus, were all situated upon a diffusely reddened and thickened skin, whereas in the case described the bridges and islands of skin between the blebs and gangrenous spots were entirely normal, being pale and supple, the necrotic lesions occurring upon previously sound skin. The entire absence of any symptoms, subjective or objective, from the side of the nervous system, excluded from consideration any of the tropho-neurotic varieties of gangrene, and after having convinced himself by physical examination that there was no reason for suspecting atheromatous change in the blood-vessels, the author came to the conclusion, that the cutaneous gangrene in this case was due to the presence in the tissues of some foreign substance, possibly sugar. The patient suffered neither from polyuria nor polydipsia, but an examination of the urine by Professor Ludwig showed the presence of sugar in the quantity of 5.15 per cent.

Under suitable treatment the amount of sugar contained in the urine became very much diminished, and the pathological process in the skin was arrested, so much so, that all the necrosed tissues were cast off and cicatrization began. Relief was only temporary, however, and the patient died six months after the beginning of her malady, cutaneous gangrene reappearing with renewed vigor, about two months before death.

The author discusses the following varieties of cutaneous disease, to which diabetes may bear a causal relation: —

(1.) Anidrosis or asteatosis cutis (Xerosis).
(2.) Pruritus cutaneus.
(3.) Urticaria chronica papulosa.
(4.) Acne cachecticorum.
(5.) Roseola and erythema.
(6.) Eczema (more especially eczema genitalium, balanitis, vulvitis, mycotica, furunculosa, and gangrenosa.)
(7.) Paronychia diabetica.
(8.) Furunculosis and carbuncle.
(9.) Gangræna cutis.
(10.) Papillomatosis diabetica.

All the different varieties of dermatosis diabetica have a common cause, the presence, namely, of sugar in the cutaneous tissues. This is found in all the tissues, exudations, and secretions of diabetic patients, and its presence was demonstrated in pus from the case reported. The irritation set up by the sugar itself or by one of its products of decomposition, affects sometimes the sensory nerves, in this way causing pruritus, in other cases the secretory and vaso-motor nerves are acted upon, thus giving rise to anidrosis, asteatosis or urticaria, and finally, inflammatory changes may be set up by direct irritation of the blood-vessels and cutaneous tissues. As a rule in these cases the tissues manifest only slight tendency to inflammatory proliferation, but on the contrary are prone to undergo necrobiosis.

TREATMENT OF LUPUS.

Doutrelepont[1] is a firm believer in the tuberculous nature of lupus, and is of the opinion that this disease should be ranked with the chronic infectious maladies of the skin. With the idea of killing the bacillus, which he considers to be the cause of the disease, he has treated lupus by the application of corrosive sublimate. Compresses soaked in a solution of corrosive sublimate were applied to the diseased regions of skin, covered with gutta-percha paper, and secured in place by a bandage. Beginning with a solution of bichloride of mercury, of a strength of one part to 20,000, it was soon found that a solution of one tenth of one per cent. was well borne, and followed by no untoward consequences. It was seldom that a dressing of the latter strength caused any pain, and under its application fungous granulations became levelled and disappeared. Suppuration was much diminished, and cicatrization at the borders of ulceration soon became manifest. The

[1] Monatshefte für prak. Derm., No. 1, 1884.

diseased regions which had not ulcerated and were still covered with epidermis became softened and in part cast off, while the tubercles and nodules peculiar to the disease disappeared. Thickened and infiltrated portions of the skin became more flexible and less reddened, while the neighboring and healthy regions of skin were in no way irritated or inflamed, but, on the contrary, the surrounding cutaneous hyperæmia diminished, and the only effect produced upon sound skin was to cause moderate desquamation. The resulting cicatrices were smooth, and under this form of treatment an advance of the pathological process was not observed. In no case did salivation occur. A modification of the above treatment was adopted in some cases by Doutrelepont, in which the application of corrosive sublimate was preceded by scraping with the sharp spoon.

Unna,[1] likewise inspired by the conviction that lupus is cutaneous tuberculosis, strongly recommends the use of corrosive sublimate in the treatment of this disease. The best manner of application he considers to be in the form of a plaster, containing for each part of corrosive sublimate ten portions of sulphoichthyolate of potash. The part played by the sulphoichthyolate of potash in this method of treatment is to counteract the keratolytic (epidermis loosening) action of the corrosive sublimate, and thus insure a more rapid healing. Six cases of lupus have been treated in this way by Unna, each one with good result.

Schulz,[2] also with bactericidal intent, has for the last ten years treated lupus by the application of a saturated solution of permanganate of potash in cold water. Such a solution is painted over the diseased regions of skin daily, or every other day, until a thin, black crust is formed. An ointment containing five per cent. of permanganate of potash or simple ointment, according to the sensitiveness of the skin, is applied upon the days when the solution of permanganate of potash is not employed. After several repeated applications of the latter at one sitting there ensue a moderate amount of pain and some redness of the surrounding skin. The lupus nodules are, so to speak, loosened by this method of treatment, and after each sitting portions of diseased tissue may be wiped out with a bunch of cotton. The above treatment is continued for a long time after the destruction of the nodules peculiar to the disease, and at the same time the sound skin in the vicinity is also subjected to vigorous painting with the same solution. The defects of tissue heal slowly from below, and there ensues a flat, red scar, which, under continued treatment, becomes paler, and finally so resembles the normal skin in color that the formerly diseased region is only to be detected by careful examination. There is no disfiguring loss of substance, and the pathological process is arrested. Relapses are uncommon, and are always easily controlled by renewed treatment. In some instances before the application of the permanganate of potash the lupus nodules were removed with the sharp spoon, the effect of which was to increase the pain, but shorten the duration of treatment. The length of time necessary for the cure of outpatients by this method of treatment is stated by the writer to be from eight to ten weeks.

Schwimmer[3] has treated lupus by the application of an ointment containing from ten to fifteen per cent. of pyrogallic acid followed by ung. hydrarg. Upon the entrance of the patients to the hospital all crusts and scales were removed from the diseased regions of skin by the liberal use of vaseline. There was then applied to the whole of the diseased surface a salve containing ten per cent. of pyrogallic acid. This dressing was retained for from four to six days, being renewed two or three times in every twenty-four hours. At the end of this time the face was again anointed with vaseline for a day, and the diseased surface was then covered with mercurial plaster, which was kept continuously applied, the frequency of its renewal being determined by the amount of suppuration present. Cicatrization was almost complete by the end of from ten days to two weeks, although there usually remained behind several nodules, which were visible in the forming cicatrix. In such cases the application of pyrogallic acid was renewed, to be again followed by mercurial plaster. Occasionally the second application of pyrogallic acid caused much pain, in which case it was replaced immediately by the mercurial plaster. In certain cases in which the skin was indolent and tolerant of treatment as many as three such cycles of treatment were employed, but more than this number was never found to be necessary. The mercurial plaster was always kept applied until cicatrization was complete. Of ten cases of lupus treated in this manner the results in eight were eminently satisfactory, and the average duration of treatment was about eleven weeks.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

OCTOBER 27, 1884. The President, DR. CHARLES D. HOMANS, in the chair.

CYSTIN IN URINE.

In the unavoidable absence of DR. W. C. B. FIFIELD the following notes of his case were read by DR. E. G. CUTLER: —

W. S., aged twenty-two years. Born in Scotland. Came to this country in April, 1884. About five years ago, being then seventeen years old, had an attack of frequent and painful micturition. When the desire to pass water was felt it had to be attended to or the pain became doubly severe. This condition of affairs had soon disappeared, and he had felt perfectly well until September 27th of the present year. Being then away on a vacation, he was seized with a peculiar pain in the left flank, very sudden in its attack. On the following day (Sunday) the pain continued, but water was freely passed until the next (Monday) morning. Then pain beyond endurance was experienced on making water. The pain was felt in the penis during micturition, but when the act was accomplished it vanished for the moment. He was obliged to urinate every hour and a half for six hours. When I saw the patient he described his urine as coming in gusts, as though when passing it was interrupted by blasts of air. Fluid extract of buchu was prescribed, and by the following night all symptoms had passed away.

DR. E. G. CUTLER said that in examining the urine Dr. Fifield met with certain crystals in the sediment,

and not readily determining their nature brought the specimen to him. The crystals were flat, six-sided, colorless plates, which dissolved on the addition of nitric acid, and on heating left a brownish-colored mass, which did not give the murexid reaction of uric acid when treated with ammonia. The rest of the crystals were collected, dissolved, and reprecipitated by acetic acid. The crystals then were determined to be cystin. The remaining portion of the urine was allowed to undergo the acid fermentation, when more cystin crystals were deposited. Cystin is a substance rich in sulphur, and readily splits up, giving rise to sulphuretted hydrogen. It is not known where cystin is produced in the body, but it has been found once in the kidneys and once in the liver; also in the sweat. The only danger arises from the liability to the formation of calculi. The disease appears chiefly in the male, in the proportion of two or three to one, and infants and young adults are the persons chiefly affected; it rarely or never has been seen after the age of fifty.

Through the kindness of Dr. Wood the dried crystals of cystin were shown under the microscope. A specimen of the above urine was obtained a couple of days ago, and found to be free from albumen, pus, or any organic matter except cystin. This urine had, at the time of the meeting, undergone decomposition with the development of sulphuretted hydrogen.

DR. E. S. WOOD spoke as follows: When cystinuria occurs the crystals are almost always found in the sediment, and are easy to distinguish if the following points are remembered, namely: that cystin crystals are colorless, and occur in the form of hexagonal plates, which sometimes show lines radiating from the centre, or in prisms; that these crystals are soluble in hydrochloric acid or other mineral acids, in the fixed alkaline hydrates and carbonates, and in ammonia, but are insoluble in acetic acid, by which cystin may be precipitated from the urine when it exists in solution. It differs, therefore, from hexagonal or prismatic crystals of uric acid in color, the latter being more or less deeply colored, and in solubility, the uric acid being insoluble in hydrochloric acid, while cystin is soluble.

Cystin contains twenty-six per cent. of sulphur, and readily undergoes decomposition in urine which has become ammoniacal, sulphuretted hydrogen being one of the products of the decomposition, hence the strong odor of this gas which this specimen of Dr. Cutler's possesses.

Cystin is also sometimes eliminated by other glands, as the sweat glands, and may then become decomposed and evolve sulphuretted hydrogen, in which case it causes silver coins in the pocket to become black, a fact which should always lead to the examination of the urine for cystin.

He also said that although the fixed alkaline carbonates dissolve cystin, these should never be used as drugs in the treatment, since they may cause a deposit of earthy phosphates to form around the cystin concretion as a nucleus.

DR. E. G. CUTLER reported a case of

DOUBLE PNEUMONIA IN A MAN WITH SLIGHT AORTIC STENOSIS OF LONG STANDING AND POSSIBLE ATHEROMA OF THE CORONARY ARTERIES. RECOVERY.

In October, 1883, I was suddenly called to see Mr. P., seventy-two years of age, a large, stout man who had for many years suffered from some form of heart disease following rheumatism, and had been told ten years before by his attending physician that he might die at any moment. He was found to be suffering great pain in the cardiac region, brought on apparently by a little over-exertion. This was the second very severe attack he had had, though there had been numerous slighter ones for a long time, apparently due to the same cause. At times he had been dizzy, but had never fallen, though frequently obliged on such occasions to sit down. The pain often extended through the back, and was of a sharp, agonizing character. Going up a flight of stairs caused dyspnœa, and was likely to bring on the pain.

Physical examination gave a very feeble cardiac impulse in the fourth intercostal space just outside the nipple. The percussion area of dullness was a little increased. The cardiac sounds were rather feeble, heard loudest at the apex on the fifth rib, just outside the nipple. There was a systolic murmur heard loudest at the apex and not propagated to the left, and an aortic direct murmur followed into the carotids and not succeeded by a distinct second sound. There was accentuation of the pulmonic second sound and slight enlargement of the right side of the heart. The pulse at the wrist was powerful, 60 to 70 in the minute, and regular. The recumbent position was impossible on account of dyspnœa.

Half grain doses of morphia by the mouth were required for a few days to ease the patient. With tincture of chloride of iron and wine of coca the man was as well as usual in two weeks. The pulse remained 64 to 66 in the minute, the physical signs were the same, the mitral murmur was recorded as slight, and there were several attacks of sudden dizziness during the next month, when the patient passed from observation. A diagnosis of slight stenosis of the aortic orifice was made, with possibly atheromatous coronary arteries which was cause of pain. For the next three months the patient was not seen.

On January 20, 1884, I was again called, and found that he had suffered from a bad cold for a week past, attended with cough and expectoration, but no fever. At noon that day he had suddenly been seized with pain in the left side under and below the nipple, which caused the respiration to be suppressed. The face was very red, the skin hot; pulse 120 in the minute, temperature 103.5° F. On physical examination merely general coarse mucous râles and percussion resonance all over the chest were found. The respirations were thirty-two in the minute. There were slight cough and slight expectoration. At night the pulse and temperature were considerably higher, otherwise the condition was the same. Dyspnœa was very marked. Cough troublesome and frequent.

The next day the cough was a little less frequent, expectoration more abundant and extremely sticky. Some sleep had been procured by means of morphia.

The following day rusty sputa were observed. The pulse, temperature, and respiration had all along remained high, and the dyspnœa and cyanosis had increased. The physical examination of the chest gave coarse râles and undiminished resonance till the 23d, when at my first visit I found a pulse of 105, a temperature of 104.5° F., and beginning flatness at the lower angle of the scapula and bronchial respiration. These physical signs increased in area till they occupied the entire lower lobe. The pulse then rapidly fell to 98, temperature to 99° F., and the respiration to 26.

Resolution began thirty-six hours after the consolidation was observed, and went on with intermissions for the next three days, when it was nearly complete, leaving the patient very weak.

During the succeeding night there was a sudden pain in the right side, a great accession of dyspnœa, cough, and temperature, and, on being hastily summoned, I found to my dismay that the same thing was beginning on the right side at the root of the lower lobe. It hardly seemed possible that the patient could survive this new attack. But a relatively small portion of the lower lobe of the right lung became involved, however (certainly not more than half). The process of resolution began at the end of the second day and ended in less than a week. In the mean time the physical signs had increased again in the left so that it was not till the 5th of February that all signs had disappeared in the right and nearly so in the left lung. On the 10th of March he was well enough to be allowed to walk out in the sunlight for a short time in the middle of pleasant days.

The treatment consisted of alcoholic stimulants, morphia, quinine, and ipecacuanha at first. During the great dyspnœa, as ordinary food seemed to increase his distress, he was given peptonized liquids, and poultices of bran mixed with red pepper and mustard were applied.

It was eighteen days before every physical sign of pneumonia disappeared.

DR. CUTLER also reported a case of

PNEUMONIA COMPLICATING CHRONIC ENDOCARDITIS AND ACUTE PERICARDITIS.

In February, 1884, Charles K., aged twelve, came under my charge with severe acute articular rheumatism. A mitral systolic murmur developed, and after an illness of several weeks he was left with a seriously impaired heart. During the past summer he has been unable to do much except slowly walk about at the sea-shore. At this time the cardiac area of flatness extended nearly one inch to the right of the sternum in the third intercostal space. The upper border of flatness began at the second rib and extended below to the fifth interspace, one inch outside the nipple. A loud systolic murmur was heard, most distinct at the apex, propagated towards the left, and audible in the back. Extra exertion was not possible, and the patient appeared quite anæmic. Swelling of the feet occurred several times, but disappeared.

October 19th I was called as the patient had suffered from pain in the legs, and had been feverish for the past three days or more. There was much pain, redness, and swelling of the right knee and wrist, and below left nipple, and some pain in the left shoulder. The temperature was 103.5° F., the pulse 120, respiration 35, and catching. That night, in addition, pain in the præcordia was complained of, the respiration was very labored, and dyspnœa great; patient had to sit erect the whole time. As my attention was attracted to the rheumatism chiefly, and it gave such pain to move him, I had examined the heart alone, and did not attempt to see what was the condition of the lung. The next morning a marked friction sound was found at the base of the heart, which quickly spread all over the cardiac area. Consolidation of the left lower lobe was found, with bronchial breathing and flatness on percussion. The dyspnœa was excessive, and the patient's mother sat holding him up with a pillow all that day and most of the succeeding night. On the 23d the whole lobe was solid, and the patient was found to be decidedly easier. The extent of pericardiac distention must have been great at the height of the disease, but its boundaries could not be accurately determined because of the pain caused by percussion. Until the 26th the pericardial friction sound has masked all cardiac sounds heard in front. The bronchial respiration and flatness of the lower lobe continue, but beginning moist râles are to-day found in the middle of the left back. The patient has a respiration of about 26 to the minute; the temperature is 100.2° F. He feels fairly comfortable, though for the past two nights he has had two rather severe suffocative attacks.

(November 4, 1884. The condition remains essentially the same as at last report. Several very severe attacks of rheumatic pain have occurred in the joints accompanied by high fever. The lung is still solid, and loud bronchial breathing is heard throughout the greater part of the left chest.)

DR. F. C. SHATTUCK expressed his deep interest in Dr. Cutler's paper, which emphasizes so pointedly the fact that a patient with organic disease of the heart may not only live many years in comfort, but also be able to withstand such a serious disease as pneumonia. The two cases of mitral disease are especially noteworthy in this latter respect by reason of the great strain thrown on the already burdened right side of the heart by the pulmonary consolidation. In the case of the old gentleman it would seem that the murmur heard at the base and propagated into the carotid must have been due rather to roughening at or near the aortic orifice than to actual stenosis. The physical signs do not indicate such an increase in the power of the left ventricle as is characteristic of aortic constriction in a state of fair compensation. In this condition the capacity of the ventricle and consequently the size of the heart is apt, other things being equal, to be less increased than in aortic regurgitation, in which the cavity receives supplies of blood from two sources at once while relaxing in diastole; but compensation implies a powerful muscle to overcome the obstruction to the blood current. Physicians generally take a far less hopeless view of valvular heart disease than they formerly did, and patients are reaping the benefits of the change.

DR. S. L. ABBOT remarked that the last speaker had anticipated him in speaking of the importance of using great caution in communicating to a patient any evidence which a physician might detect of cardiac disease, especially where the consciousness of the patient had not excited apprehension of any such trouble. The announcement of any organic trouble of this kind was regarded by most people as a sentence to sudden death. Of course it was not necessary before this Society to say that in a majority of such cases death followed a longer or shorter condition of invalidism, and was not instantaneous. The gentlemen present who had made examinations for life insurance must have had occasion, as he had done in a limited experience of this kind, to detect valvular murmurs which had not been associated with any subjective symptoms whatever. The announcement of such a discovery, unless circumstances made it absolutely necessary, he thought should be avoided if possible, or the nature of the trouble detected communicated in such a way as to avoid the terrible construction which most people put

upon it. Instances are not uncommon, as of course was well known to the gentlemen present, in which such a murmur, even when supposed to be due to organic cause, subsequently disappeared, or, if it continued, was only followed after a long interval, if ever, by serious discomfort to the patient, and which did not terminate in sudden death. He instanced a case of a patient now in perfect health so far as the heart is concerned, who, years ago, was thrown into a state of great alarm, as well as all the members of the family, by the announcement of the existence of heart disease, based on the discovery by the family physician of a slight aortic souffle. The patient was a lady in delicate health, of highly nervous organization. Not a trace of this murmur has existed now for ten or twelve years. In another recent instance similar alarm has been excited by the announcement of valvular disease of the heart to a lady, of his acquaintance, in whom no marked evidence of cardiac disability had shown itself, at least not enough to excite any apprehension of organic disease on the part of the patient or her friends, who all now feel that she may fall dead at any moment. Such an apprehension is hard to remove by any explanation, and he feared that too often physicians in their conscientious desire for accuracy of diagnosis in such cases were led into statements which conveyed a more serious meaning than they appreciated or than the indications justified.

DR. F. W. GOSS reported

A FATAL CASE OF PUERPERAL CONVULSIONS PRECEDED BY EXCESSIVE EPIGASTRIC PAIN.[1]

DR. C. M. GREEN said that since hearing of Dr. Goss's case he had searched for the literature of the subject, but without finding other cases than those mentioned by the reader. The description by Leishman is most vivid. He suggested that elimination of urea by the stomach might give rise to gastralgia.

DR. O. W. DOE said he had listened with great interest to Dr. Goss's paper, as it recalled a similar case occurring in his own practice. The patient, a primipara, thirty-two years of age, had a very easy confinement with twins. There had been no symptoms suggesting renal trouble either before, during, or directly after labor, which took place at about two A. M. At noon she began to complain of severe epigastric pain, which steadily increased, and at five P. M. she had a bad convulsion. Others followed in rapid succession, and she died at about eleven P. M., never having regained her consciousness after the first convulsion. He saw her at noon, when she first began to complain of pain, but considered it as arising from indigestion, and advised simple remedies accordingly.

DR. ABBOT said that the case reported and the supposed significance of gastralgia as a precursor of convulsions, brought to his mind the case of a lady in his practice, who in two successive pregnancies had suffered from this symptom even in a more marked degree than in Dr. Goss's patient, but without convulsions. She was at the eighth month of pregnancy, and in the absence of her physician Dr. Abbot was called. She had been suffering for some weeks from a pain at the epigastrium, which at first had been regarded as due to indigestion, and was treated as such. No relief had been obtained, and of late the symptom had increased in severity and frequency. During five days it had increased so as to amount to agony, causing great dyspnœa from interference with the movements of the diaphragm, coming on in paroxysms of some minutes' duration, and recurring at shorter and shorter intervals, sometimes as short as fifteen minutes. In degree it could only be compared to that of the severest labor pains. The urine was loaded with albumen, but of a specific gravity of 1028. The case had now become very urgent, calling for relief by premature delivery. This it was decided, on consultation with Dr. Storer, to produce. On making examination it was found that the process was already beginning, the os being dilated to the size of a quarter of a dollar. So intense, however, was the gastralgia that these pains had not been noticed by the patient. Active labor set in in a few hours, and the child was born living in about eleven hours after the commencement of the labor was detected. During this time there was no headache, and the gastralgia disappeared as the labor progressed and did not return. Albumen disappeared rapidly from the urine after the birth of the child, and a large amount of uric acid crystals with some fragments of gravel came away. During convalescence the patient suffered much from temporal and facial neuralgia. The child lived but a few hours.

Three years and a half afterward the patient went through a repetition of her experience in a subsequent pregnancy. The symptoms were, if anything, more severe than on the first occasion. The labor was premature, spontaneous, at the seventh month. There had been the same agonizing gastralgia as on the previous occasion, and for five months, as was afterwards learned, the patient had not been able to lie on her back with comfort on account of pain through the kidneys. The labor was short, only one hour and a half. Gastralgia, however, only subsided gradually after the birth of the child, requiring treatment for some days. The urine after the labor was scanty, loaded with uric acid, and contained much albumen and abundant casts; specific gravity 1014. She was nearly blind, being unable to recognize the features of a person by her bed-side until the third day after confinement. There was also much renal pain. For two weeks she suffered much from neuralgia in various places, and sight was fully restored only after some weeks. There was no head ache during labor or the blind period following, nor were there any convulsions at any time. The patient made a good recovery, the kidneys gradually returning to a normal condition. She has since been in perfect health, but she has not been again pregnant.

DR. J. P. REYNOLDS said: It did not seem to him that we need assign a special cause for the epigastric cramp. In the presence of the central nervous disturbance which is impending, severe localized pain is set up. That which is so well recognized on one or the other side of the head is one instance of this; the epigastric agony is another. While listening to the remarks of the last speakers he had recalled a fatal case of eclampsia, in a multipara, in which there were two convulsions separated by an interval of three or four hours; and during that interval the burden of the patient's constant complaint was pain over the uterus, from which a fœtus of six and a half months had been expelled. In this instance a most interesting autopsy showed both kidneys enormously swollen, engorged with blood, as in some specimens of acute scarlatinous nephritis.

The Society is under especial obligations to the reader for reporting these rare and interesting symptoms; and it is still more indebted to him and to Dr.

[1] See page 464 of this number of the JOURNAL.

Green for their careful investigation of the scanty literature of the subject. We shall all be set upon the watch for other similar cases.

OPHTHALMIC SYMPTOMS ACCOMPANYING IMPETIGO HERPETIFORMIS.

DR. F. B. GREENOUGH said that he had seen a case of skin disease on the face and side of the head, of a girl aged seven, that seemed interesting to him on account of the accompanying ophthalmic symptoms. The patient, by the report of her mother, an intelligent woman apparently, showed an impetiginous eruption about forty-eight hours before she was seen. At the time of visit there was a round patch on the right temporal region, just above the zygomatic process, nearly the size of a silver quarter of a dollar, covered with a yellowish honeylike crust, not surrounded by an areola of inflammation; another irregularly shaped and larger one above and behind the right ear, not extending outside of the hair, and a third one, oval in contour, about the size of a pigeon's egg, on the dorsum of the right hand. The pupil of the right eye was dilated so that the amount of the iris seen was not more than a line in thickness. The conjunctiva was not injected, and the other pupil was normal, reacting to light perfectly. The child was unable to give any intelligent account of her feelings as to the existence of pain, etc., nor could anything be decided as to vision.

The mother insisted that the only thing that had been applied to the eruption was some fresh lard, and denied the possibility of any atropine or belladonna having got into the eye.

The case was evidently not one of zoster, the character of the efflorescence being entirely different. It was, however, different from an ordinary case of impetigo, and was one of several that Dr. Greenough had seen in children recently, which he thought had been described as impetigo herpetiformis. Even if, however, the eruption had been a typical zoster, he thought the simple dilatation of the pupil without any symptoms of congestion, as shown by the perfectly normal conjunctiva, would be extraordinary, as in all the cases of zoster which he had seen in the region of the superior branch of the fifth pair, the affection of the vaso-motor filaments was manifested by decided ophthalmic inflammation, that is to say, where any ophthalmic symptoms existed. The mother stated that when she first saw the child, on the morning of visit, the right pupil was very much contracted.

DR. H. W. WILLIAMS said, in reply to a question by Dr. Greenough, that more or less of conjunctivitis, with disposition to corneal ulceration, is a common accompaniment of herpes zoster frontalis; as is also dilatation of the pupil; and when these conditions precede the appearance of the herpetic eruption they may give rise to the supposition that atropia or belladonna has been applied to the eye.

— An epic poem by Dr. F. W. Weber, a medical practitioner resident at Lippespringe, a health resort of N. W. Germany, entitled *Dreizehn Linden*, is spoken of by the English *Spectator* as the most important contribution made to the poetical literature of Germany since the days of Heine. Its scene is laid among the Saxons and Franks in the period following the death of Charlemagne.

Recent Literature.

A Treatise on Physiology and Hygiene. By JOSEPH C. HUTCHISON, M. D., LL. D. New York: Clark & Maynard. 1884. 319 pages.

This book, "for educational institutions and general readers," has reached the stage of being a "revised edition," and the circular of the publishers assures us that the youth of many cities are busily engaged in learning from it important hygienic lessons. If they are fortunate in having teachers well enough versed in physiological knowledge to bring in the not infrequently necessary corrections such lessons may be profitable, for the book contains much that is commendable in matter and in arrangement. The treatment of alcohol and tobacco is rather didactic, leaving the student to explain to himself why the older male members of the family have not become driveling idiots or afflicted with various complicated and wasting diseases. There is a chapter on the use of the microscope, but of the briefest and most meagre description. A longish appendix treats of poisons and emergency matters in a way to require much supplementary explanation and qualification from the competent teacher.

The illustrations of the Treatise are generally good and well printed; we have been unable, however, to decide whether the young woman, whose tight lacing furnished Fig. 5 (page 20), had only eleven ribs in the right half of her thorax.

A Practical Treatise on Surgical Diagnosis. By AMBROSE L. RANNEY, A. M., M. D. Third Edition. Wm. R. Wood, Publisher. 1884.

The appearance of a third edition of Ranney's Surgical Diagnosis within five years of the original work attests the popularity which it has acquired.

It is especially useful as a text-book and guide for students or beginners who are endeavoring to acquire a systematic habit in the investigation of disease. The present volume contains 137 more pages than the previous edition; the additional space being devoted to two new chapters upon diseases of the brain and spinal cord, in which the author treats at some length the localization of cerebral and spinal diseases.

The whole work has undergone careful revision, and is further enriched by numerous illustrations which do much to facilitate an understanding of the text.

Lectures on the Principles of Surgery. By W. H. VAN BUREN, M. D. Edited by LEWIS A. STIMSON, M. D. New York: D. Appleton & Co. 1884.

These lectures of Professor Van Buren's, beginning with the consideration of wounds and their various accompanying accidents, such as hæmorrhage, suppuration, shock, tetanus, septicæmia, pyæmia, erysipelas, etc., go on to treat of fractures, dislocations, and tumors under their more general aspects.

While the subjects are treated popularly as for presentation to a class of students, their scientific and pathological bearings are not neglected.

The book is well worth the attention of students, who will find in it vigorous statements of truths that will be constantly applicable in their future surgical work.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 13, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 Park Street, Boston, Mass.

ATONIC DILATATION OF THE STOMACH.

In a preceding number (October 30th) we referred to the pathogenesis of atonic dilatation of the stomach as set forth by MM. Sée and Mathieu in the *Revue de Médicine*. In a later issue[1] of the same periodical these writers develop their views in regard to the symptomatology, diagnosis, and treatment of this condition which unquestionably, though sufficiently common, is often overlooked or but ill understood. Even in the latest editions of our most approved text-books atonic dilatation of the stomach, as distinguished from dilatation the result of obstruction, is dismissed rather cursorily.

The symptoms vary considerably in the acute and chronic forms, in the earlier and later stages, but in general the muscular walls of the stomach are thin and the vomitus is free from blood, two points upon which to base a differential diagnosis as against obstructive dilatation. A reliable diagnosis can only follow repeated examinations.

The symptoms may be divided into physical and functional. The former declare themselves upon inspection, percussion, succussion, and auscultation and internal exploration; the latter — the functional symptoms — declare themselves by flatulence, pains (which may be spontaneous or provoked), vomiting, constipation, dyspepsia (deranged gastric chemistry), and general constitutional disturbance.

According to the predominance of one or another set of these symptoms, MM. Sée and Mathieu find it convenient to divide their cases into a simple class, a painful class, a class characterized by gastric repletion, and a dyspeptic class.

Inspection furnishes but little reliable information. The epigastrium may be unduly prominent or even very much distended, but the value of this symptom can only be determined by percussion. Sometimes peristaltic movements of greater or less energy can be seen through the abdominal walls. Percussion yields far more important information, but must be pursued methodically and with precision, and repeated frequently under varying conditions and positions. The vertical extent of the gastric tympany is the principal point. By percussing from several points of departure the upper border of the stomach can be determined without much difficulty, but the lower border is sometimes not made out so easily, though frequently, by percussing carefully upward from a point about midway between the pubes and the umbilicus until the small intestine is reached, and then diverging towards the border of the false ribs at the mammillary line, the line of the greater curvature may be also marked out. When difficulty is encountered the splashing sound of liquid in the stomach or of liquid introduced for the purpose may be of much assistance; and in all cases further information may be gained as to the gastric distention or distensibility by emptying the stomach with the siphon tube or by introducing effervescing mixtures. The healthy stomach and the dilated stomach both vary greatly, of course, in their size under different circumstances, — and even at times during an examination, — but these writers think one is justified in diagnosticating a *distention* when the upper and lower borders of the gastric tympany are found on a single occasion twelve to fourteen centimetres (five to six inches) apart, and a *dilatation* when that space is found constant at five or six successive examinations under varying conditions, and in various attitudes. The introduction of a sound into the stomach as a means, combined with external palpation, of determining the size of the stomach, as suggested and practiced by Leube, is not approved, and is stigmatized as highly dangerous. The gastric walls in many of these cases are certainly very thin. Succussion and splashing, as interpreted by auscultation, have a minor value among the physical signs of dilatation.

The functional symptoms when present, which is generally but not always the case, are characteristic and of themselves indicate strongly the presence of the condition. Flatulence in an extreme degree supervenes immediately after meals and persists for several hours accompanied by swelling and a sense of weight at the epigastrium. Pains springing from the epigastrium and radiating out towards the thorax, the abdomen, and the left hypochondrium supervene by crises varied by periods of vague, dull discomfort; these crises of epigastric pain are not accompanied by vomiting as is the case with the gastric crises of locomotor ataxia and with hepatic colics. Pains may also be provoked by pressure or by the ingestion of very cold or acid fermented drinks. The point of greatest tenderness is then usually just under the upper border of the false ribs on the right. Vomiting is not very frequent in moderate cases of atonic dilatation, but belongs especially to the pronounced forms where the stomach has become an inert pouch passively distended with a semi-liquid fermenting mass, and to cases with a hysterical element; in both of which classes the vomiting is not seldom attended by convulsions and tetanic phenomena, due to the dehydration of the blood and anæmia of the nervous centres. Constipation, often obstinate and alternating at long intervals with attacks of profuse diarrhœa, is a common symptom. The dyspepsia which may be absent, or may precede but generally follows atonic dilatation, is marked by bitter regurgitation and acid vomiting. In simple dilatation the digestion is often performed completely, a good appetite preserved, and scarcely any general depression is present. As for the constitu-

[1] September 10, 1884.

tional effects, it is not always easy to estimate how far they result from the ectasy and how far from the causes which produced the ectasy itself. Frequently there is a vicious circle, but sometimes a simple washing out of the viscus shows that the frontal headache, the malaise, the inaptitude for mental work, the vertigo, the fainting turns were secondary to and dependent upon the dilatation.

The treatment of these cases may be classed under two heads: the pathogenic and the symptomatic treatment. By the former one seeks to avoid or suppress the causes which provoke a dilatation, and to modify a general condition of health which give those causes a favorable opportunity to assert themselves; by the latter one palliates the annoyances of a state which there may be no hope of curing. The fact that simple dilatation is a tolerably common sequel to typhoid fever gives a clue to its mode of origin and mode of cure.

Excessive alimentation and substances causing gastric relaxation must be avoided. The motor functions of stomach and intestines must be regulated. Constipation it is of prime moment to overcome. The muscular coat of the stomach should be excited to action — by electricity if need be externally or internally. The attacks of pain should be controlled, and chloroform water does good service for this purpose except with some hysterical patients. For washing out it may be used in the proportion of one part to three of pure water — care being taken to leave very little of this mixture in the stomach, and to follow it by a second washing with plain water. Washing out with an alkaline water, such as Vichy, may also be employed to combat a dyspepsia accompanied by an excessive mucous or fermentative acid secretion.

Want of space has made it impossible to follow MM. Sée and Mathieu in all the details of their suggestive articles, which are not improved in form by a somewhat minute repetition of the points they desire to present, but we are glad to call attention to so praiseworthy an effort to elucidate a somewhat obscure and neglected pathological condition.

THE VITAL STATISTICS OF MASSACHUSETTS FOR THE YEAR 1883.[1]

WITH an estimated population of 1,985,335, in the year 1883, there were in Massachusetts 47,285 births, 18,194 marriages, and 37,748 deaths during the year, — 23.82 births, 9.16 marriages, and 19.01 deaths to each 1000 persons. For the twenty years from 1860, the birth-rate in this State is less than that of any prominent European country, and the excess of births over deaths is less than ours only in France and Hungary. The rate of natural increase of the population is less in Massachusetts in the native than in the foreign population.

There were 899 illegitimate births during the year, and 1489 still-born. Of those born alive the proportion of males to females was 106.6, the average for thirty years being 105.7. Of the still-born nearly three fifths were males. The proportion of illegitimate to legitimate births has doubled in twenty years, and 12.6 per cent. more are of native than of foreign mothers.

The marriage-rate was a trifle less than in 1882, but just above the rates for the previous years since 1874. Fourteen thousand five hundred and sixty-two bachelors married maids, and 795 married widows; 1795 widowers married maids, and 961 married widows. There were 2835 widowers married and 1835 widows. Thirty-six and eight tenths (36.8) per cent. of the males and 46.4 per cent. of the females were married between the ages of twenty and twenty-five; 32.3 per cent. of the males and 21.7 per cent. of the females between twenty-five and thirty; 12.6 per cent. of the males and 7.1 per cent. of the females between thirty and thirty-five; 1.7 per cent. of the males and 16.2 per cent. of the females under twenty. In sixteen marriages of males and twenty-five of females the age was not reported. Seven hundred and fifty-one men and 268 women were married over fifty years old; twenty men and two women over seventy-five, and six men over eighty.

There were 655 divorces granted during the year: 157 for adultery, 321 for desertion, 83 for intoxication, 29 for extreme cruelty, 50 for cruel and abusive treatment, 13 for neglect to provide. The number of marriages has increased from 12,513 in 1864 to 18,194 in 1883, the number of divorces from 270 to 655.

The death-rate per 1000 of the population (19.01) was .13 lower than that for 1882, .51 less than the rate in 1881, .21 lower than the average for the five years, and .25 lower than the mean for the thirty years previous to 1881. It has been exceeded but thirteen times since 1850.

In the third quarter of the year 28.38 per cent. of the deaths occurred; in the second, 24.65; in the first, 23.87; in the fourth, 23.10, the usual order being third, first, fourth, second.

The death-rate of males, like the birth-rate, was about six per cent. higher than for females. Under one year of age 835 more males died than females, or a percentage difference of 4.53; under the age of five this excess amounted to 4.85 per cent. Between twenty and thirty the deaths of females exceeded those of males 1.79 per cent., and of all other ages 3.05 per cent. Nineteen and nine tenths per cent. of the entire mortality occurred under one year of age, and 31.39 per cent. under five, — proportions which are very similar to those for a period of years. The ratios of infant mortality under one year and under five years were lower in 1883 than the average for twelve years; the proportions of deaths between twenty and thirty and for all other ages were higher.

The lowest average death-rate is for the ages from ten to fifteen, and is about four per 1000; next, about 6.50, from fifteen to twenty; and highest, nearly 200,

[1] Forty-second Report to the Legislature of Massachusetts relating to the Registry and Return of Births, Marriages, and Deaths in the Commonwealth, for the Year ending December 31, 1883: together with the Report relating to the Returns of Libels for Divorce for the Year 1883. Prepared under direction of the Secretary of the Commonwealth. With editorial remarks by Frank Wells, M. D. Boston: Wright & Potter Printing Co., State Printers. 1884.

under one. The average age of all persons dying has been rising in the last few years, owing to the decreased infant mortality.

From "zymotic" diseases the death-rate for 1883 was less than for any year since 1872, and 5.1 below the average for the past twelve years: —

MORTALITY FROM PROMINENT "ZYMOTIC" DISEASES.

Years	Dysentery.	Typhoid Fever.	Whooping-Cough.	Croup.	Diphtheria.	Measles.	Scarlatina.	Cholera Infantum.	Small-Pox.	Total.
1872	594	1703	363	480	273	428	1377	3254	1029	9471
1873	435	1406	294	435	310	180	1472	2553	668	7723
1874	366	1147	449	411	502	161	1382	2222	26	6706
1875	437	1059	242	689	1200	233	1684	2606	34	8175
1876	417	881	192	684	2610	47	1222	2087	31	8171
1877	580	814	369	544	2634	135	467	1927	26	7496
1878	602	679	400	583	1934	305	404	1573	2	6482
1879	372	637	302	559	1734	19	850	1949	8	5830
1880	395	882	220	625	1769	236	574	2118	38	6867
1881	360	1072	217	677	1706	230	397	1861	47	6567
1882	398	1079	265	491	1280	68	318	2159	45	6103
1883	336	869	137	530	1091	321	575	1941	5	5796

Pulmonary consumption caused 5931 deaths in 1883, as compared with 5865 in 1882, and 5886 in 1881. From cancer the deaths were 1026, or thirty-nine more than the previous year. For many years, the reported mortality from pulmonary consumption has been decreasing and from cancer increasing. There has also been a striking increase in the fatality from Bright's disease and from cerebral diseases.

In 1883 there were 3562 deaths from disorders of the brain, — 1845 males and 1717 females. Of this number, 495 males and 561 females died from paralysis; 596 males and 469 females from "cephalitis"; 412 males and 372 females from apoplexy; 87 males and 96 females from insanity; 74 males and 48 females from "softening of the brain"; 181 males and 171 females from unspecified diseases. From apoplexy and paralysis, taken together, there occurred 546 deaths between the ages of seventy and eighty; 436 between sixty and seventy; 395 over eighty; 253 between fifty and sixty; 142 between forty and fifty; 84 between thirty and forty; 74 under thirty; 18 under five. Comparing the statistics of 1883 with those for 1860, since which year there has been almost unbroken advance in the mortality from brain disorders, it will be found that there has been an increase of 156.9 per cent. in the number of such deaths, as against an estimated increase of 61.2 per cent. in the population. In the same period apoplexy has advanced 229.4 per cent. in its mortality, paralysis 162.6, and insanity 157.7 per cent. There has been an almost steady annual increase in the number of deaths from Bright's disease from 140 in 1870 to 582 in 1883, or 315.7 per cent.

The number of deaths from heart disease, bronchitis, pleurisy, peritonitis, and pneumonia remains quite high.

The various accidents of pregnancy and labor were less fatal by forty-six deaths than the twelve years average. Adding the number of deaths from puerperal fever (127) to the other fatal accidents of childbirth, the result gives, as a proportion, one death in every 145.4 labors, as compared with 140.5 in 1882, and 136.6 in 1881.

Of the violent deaths, 448 were from drowning and loss at sea, 185 from railroad accidents, 167 from suicide, 106 from burns and scalds, 76 from suffocation, 50 from heat, 39 from poison, 18 from exposure, 14 from strangulation, seven from homicide, four from freezing, four from lightning, one each from the administration of chloral and chloroform.

The report, with accompanying tables, from which we have made the above extracts, is to be had at the document room in the State House, and will well repay careful study.

CHOLERA IN PARIS.

THE presence of cholera in Paris is now known, acknowledged, and officially recognized. Sporadic cases have undoubtedly occurred through the summer, and it is probable that the reports of such which were in circulation late in June and early in July were correct. The French daily papers say that from June 20th to the first week of this month there had been 160 cases of cholera in the city with sixty deaths. There was quite a little epidemic in July at Aubervilliers, a town of 8000 inhabitants, four or five miles north of Paris, which is provided with a miracle-working picture of the Virgin, but not with good water and drainage. Now the disease seems to have established itself pretty firmly in the poor quarters of St. Antoine and Menilmoutant, and further concealment is impossible. The chief centre is said to be in a miserable little street running out of the Faubourg St. Antoine, about half-way between the Bastile Square and the Place de la Nation. In this short street there are fifty-eight rag houses and thirty-three saloons of the lowest kind.

All the daily newspapers contain telegraphic reports of the number of fresh cases and deaths since Wednesday, November 5th, but these reports are conflicting and unreliable. During the forty-eight hours from Friday morning to Saturday midnight there were reported 183 new cases and sixty-three deaths. Quite a number of cases are, probably, not reported at all to the authorities. Cases are also reported from several towns in the northern departments, from Nantes, Montreuil, St. Nazaire, and from places on the Channel near Calais.

The weather in France has been mild, foggy, and rainy. In Paris there is at present a great deal of poverty, owing to long-continued depression in business; the water supply from the Seine is hard, and predisposes to diarrhœa; the sewers are better adapted for exhibition to admiring strangers than for removing waste.

In the three first cholera epidemics, those of 1833, 1848, 1854, France and Paris were invaded from England, which in turn derived the disease from North Germany, the poison attacking Europe by land. In 1865–1866 it entered Europe at Constantinople,

and France at Marseilles, being transported, as in the present epidemic, by water, and approaching Paris from the south.

MEDICAL NOTES.

— Dr. S. Weir Mitchell records in the July number of *The American Journal of the Medical Sciences* three cases of hysteria in which there was unilateral increase in bulk at or near the menstrual period, and also at other seasons after emotional excitement, and he has been unable to find elsewhere any narration of similar cases. The writer cannot explain the causes of this phenomenon further than to say that they are under the influence of the nervous system, and vary with the causes which also increase or lessen the analgesia or give rise to chronic spasm. Most probably, he thinks, in many unilateral hysteric palsies a like phenomenon exists, and has merely escaped attention because of being the least prominent in a group of symptoms. At all events it adds another to the large group of resemblances which so closely relate organic to hysteric hemipalsy.

— Among the indictments returned last week by the grand jury for Suffolk County was one for manslaughter against Dr. Helen Cumming, of South Boston, for causing the death of Isabella B. Hill on August 1st last. Mrs. Hill at the time was visiting her friends in South Boston, and suffering with a cold, called in the defendant to prescribe for her, and in leaving medicines Dr. Cumming carelessly gave a poisonous dose of fluid extract of St. Ignatius bean, and on taking it, according to directions, Mrs. Hill only survived the first dose about three hours. This case is similar to that of one Pierce, an irregular medical practitioner of Worcester, who was convicted of manslaughter in administering kerosene oil to a patient, and which is now pending before the full bench of the Supreme Court on exceptions, and a final decision in which will be of great interest to the public.

Correspondence.

CONSERVATIVE SURGERY.

MR. EDITOR, — I wish to draw the attention of the profession to a work on surgery by Henry G. Davis, M. D., now of Newton, Mass., published by D. Appleton & Co. in 1867.

It has not received the wide recognition and credit due to it or to its distinguished author. Many of the important points brought out in this valuable work were original with Dr. Davis, and were by him first introduced to the medical profession of New York.

In this short note I purpose referring to a few of the most important and interesting points contained in the work with the hope that this volume will find its way more widely to the libraries of the general practitioner, especially those remote from the large cities, the country physician.

In the opening article on Fractures the doctor makes the broad assertion "that when adhesive plaster is applied over the bellies of muscles and extension made therefrom the effect in restraining the action of the muscle is the same as when extension is made from the bone into which the muscle is inserted." He then goes on to prove this principle, and illustrates in fracture of the patella, fracture of the processes about the elbow, and more at length in intercapsular fractures.

Then follows a discussion on "Old Dislocations," in which the old method of treatment is condemned, and a new one, the result of his own investigations, brought forward instead. This principle is contained in the three words, "continued elastic extension," and applies to all dislocations, which, Dr. Davis asserts, can be successfully reduced *without violence*. He maintains that the *continuous elastic extension* elongates the soft tissues, corrects deformities, and restores the parts to a normal condition. The same rule applies to the ligaments as well as all other tissues. Length of time that a dislocation has existed does not debar a successful issue by his method of treatment.

Dr. Davis applies his treatment upon the principle above set forth successfully in congenital dislocations as well as those following traumatic injury. In morbus coxarius and diseases of other joints he claims to be equally successful, and in all he illustrates by plates and diagrams as well as clearly worded descriptions of his methods and appliances.

The advantages of *continued elastic extension* the doctor considers to be twofold: first, the gradual overcoming of the contraction of muscular tissues, and second, the lengthening of all the shortened tissues. This is effected by the new material deposited, which, being in a plastic state, must necessarily be longer when organized than the old, whether that be muscle, tendon, or ligament, and thereby the tendency to contraction or shortening be remedied.

On this principle he has reduced dislocations of the hip at all periods up to fourteen years, and this was done without injury to the parts or suffering.

In his article on Congenital Dislocations he gives many interesting facts, and clearly describes the manner in which reduction can be effected and maintained.

The best effects of *continuous elastic extension* are most marked in diseases of the joints. In morbus coxarius it overcomes muscular contraction, thereby removing the pain and rendering the patient comfortable and free to exercise and enjoy the days while recovery is taking place. One writer has clearly described the beneficial effects and relief obtained in the words, "It robs the disease of all its terrors."

The principle, in Dr. Davis's treatment of disease of the joints, is to keep the diseased surfaces separated until the parts have healed, then trouble will not ensue when they are again brought in contact. He considers the pressure caused by the contraction of the muscles as the principal cause of the destruction of the joint, and if the treatment is commenced in the early stage the patient will recover with a good joint. The doctor has devised apparatus — some twenty-five different splints and appliances — for carrying out his ideas.

The doctor is very emphatic in his declaration that bony union, or anchylosis, never takes place between ulcerated bony surfaces any more than it will between ulcerated surfaces of the mucous membrane; that the fixture is from the shortening of all the tissues about a joint, and can be overcome by continuous extension; that he has restored full motion even after fourteen years of fixture, and that his plan of treatment gives greater hope of success than any other.

His interesting chapter on Pott's Disease describes how the form can be kept erect, with his appliances, and deformity prevented.

His chapter on Phthisis Pulmonalis is very interesting and instructive, and contains many ideas new and valuable.

Dr. Davis's Conservative Surgery takes up and discusses only a few of the many diseases the surgeon is called upon to treat. But these few are handled in a masterly manner, his descriptions being clear and concise, his methods and plans of treatment excellent, apparently founded on accurate scientific principles, and taken altogether this is really a valuable contribution to the profession. J. F. FRISBIE, M. D., Harv., '61.

NEWTON, MASS.

"TUMORS OF THE BLADDER."

MR. EDITOR, — In your report of a recent discussion upon "Tumors of the Bladder," the subject of suprapubic incision does not, I think, receive the notice it deserves, and I take the liberty of sending you a report of my remarks upon the present state of our knowledge in regard to the relative value and applicability of the suprapubic and perineal incisions in dealing with these neoplasms: —

I said that I thought the question of preference between the median perineal operation (French boutonnière) and the suprapubic incision for these cases ought to be considered still an open one.

The suprapubic operation fell into disrepute and disuse during the time before antiseptic methods were properly understood.

This operation has for some years been the subject of much study by Continental surgeons, and many improvements in method have been introduced which greatly simplify the procedure and obviate previous difficulties.

One of the most important of these is the use of the rectal balloon of Petersen. This is employed as follows: The bladder is filled with water, and a rubber bag attached to the nozzle of a syringe is then introduced into the rectum. As this is inflated, the bladder is pressed upwards and forwards against the abdominal wall, and fixed there. The anterior peritoneal fold, always the bugbear of the operation, is lifted up out of harm's way, so that with ordinary care it can be avoided.

Another recent improvement in this operation is the application of thorough drainage to the bladder wound. Formerly efforts were commonly made to close the wound in the vesical wall with sutures. But although this attempt sometimes succeeded it not infrequently led to a fatal infiltration of urine. It is now found to be safer to leave the bladder wound widely open, and to introduce one or more large tubes through it to supply necessary drainage until the loose cellular tissue about closes itself by granulation. Excellent results are claimed for this method.

Professor Guyon prefers the suprapubic incision for dealing with neoplasms of the bladder on the ground (1) that the high operation, by allowing free access to the viscus, gives opportunity for a much more thorough and certain removal of the new growth; (2) that the possibility of getting the finger in alongside of the instruments lessens the danger of nipping or otherwise injuring the bladder wall; (3) that no important parts are injured by the suprapubic incision, which also avoids the danger of hæmorrhage; and (4) that the wound can be made and dressed antiseptically, thereby reducing the chances of septic infection.

If this belief in the comparative safety of the high operation, which Professor Guyon shares with so many other Continental surgeons, is well grounded, it will certainly be conceded that in view of the much easier access it affords to the bladder it should be employed in cases where the growth is presumably benignant, and a thorough removal is necessary to prevent its recurrence.

When, however, the symptoms are those of a malignant growth, and the object of interference is mainly to establish drainage, the operation which enters the bladder at a dependent point is manifestly best.

Truly yours, A. T. CABOT, M. D.

3 MARLBOROUGH STREET.

Miscellany.

PREVENTION OF OPHTHALMIA NEONATORUM.

DR. HENRY J. GARRIGUES writes on this subject, in the *American Journal of the Medical Sciences* for October, detailing his experience in the New York Maternity Hospital, where the character and social grade of the patients is such as to make the disease very common. The results of curious treatments are given, including carbolic ante-partum injections, but the percentage of cases remained high, and the prognosis as to sight bad. Credé's method, introduced in the year 1880, consists in *washing the outer surface of the eyelids with plain water, separating them slightly, and letting a single drop of a two per cent. solution of nitrate of silver fall from a glass rod on the cornea.* No after-treatment is used. Since Credé introduced this method in his clinic in 1880 until the end of March, 1883, he treated 1160 children in this way, and only four, that is, little more than one third per cent., were affected, and of these two or perhaps even three must be eliminated on account of particular circumstances, so that in reality the percentage becomes almost none.

This method was introduced by Dr. Garrigues on the 14th of October, 1882, in Maternity Hospital, and kept up till the end of March. After that time it was discontinued, but during his next term, from the 1st of October, 1883, till the 31st of March, 1884, he followed the same plan. Thus it was tried for almost twelve months, during which there were born 352 living children in the hospital. In one case which during the absence of the house surgeon was delivered by an assistant, the application was neglected, and this child had a purulent conjunctivitis with opacity of the cornea. Although it was transferred to the eye ward in order to be under the treatment of specialists for diseases of the eye the case ended in complete loss of sight in both eyes. As a counterpart to this, *of the 351 children who were treated as prescribed not a single one was affected.*

In a few cases was observed a slight serous discharge from the conjunctiva. In the first of this kind that occurred compresses dipped in ice-water were applied,

and the eyes washed with a saturated solution of boracic acid. Later no treatment whatsoever was used, and the slight irritation, which evidently was due to the instillation, disappeared in the course of a couple of days. How little the eyes are affected by the silver solution is best shown by cases in which, through carelessness, so much of the solution was introduced that the eyes became surrounded by black rings. This happens easily in the hurry of a delivery room if the application is made with one of the common squirters which are used for counting drops. It is, therefore, better to use a small *solid* glass rod, which retains only a single drop when dipped into the bottle containing the solution. This application is made immediately after the cord has been severed, which is not done before the pulsation in it has ceased. During the following ablution great care is taken that no foreign substance enters the eyes.

As some might think the treatment unnecessarily harsh, it is stated that Hecker, in Munich, used a one per cent. solution of nitrate of silver, and had almost as many cases of ophthalmia neonatorum as before. Credé himself tried first a solution of borax (one to sixty) without satisfactory result. His treatment with the two per cent. silver solution having almost banished the disease from the lying-in wards, and no bad accidents having occurred in the thousands of cases in which it has been used, there seems to be good reason for adhering strictly to the method as practiced by its originator.

The writer does not recommend this treatment as yet as a routine in cases of private practice in view of the comparative rarity of the disease in such cases, and because until the treatment and its immense value have become more generally known in and outside of the profession the physician might be blamed if it should happen that the eyes became a little inflamed, as they do in some cases. The only exception he would make from this rule, for the time being, is when it is known that the mother or father of the child recently has had a gonorrhœa. Here the danger for the child is so great that we ought to protect it, which easily can be done under some plausible pretext. Even if the gonorrhœa in the father is of old date it might be advisable to have recourse to the preventive treatment, since Dr. Noeggerath has shown how persistent this disease may be even without giving rise to any symptom which would call attention to it.

POISONING BY CANNED FOODS.

HIS attention being called to the subject by the occurrence in his practice of six cases of corrosive poisoning, according to his diagnosis, from eating canned tomatoes, Dr. John G. Johnson, of Brooklyn, New York, inquired into the general question of poisoning by canned goods, and presented a paper on it before the Medico-Legal Society of New York, April 9th of this year. We reproduce the general conclusions of this paper as an answer to some of the queries excited by our editorial comments of October 16th on the Safety of Canned Foods: —

(1.) The six cases were not cases of sickness from spoiled tomatoes. (2.) They were cases of corrosive poisoning from muriate of zinc and muriate of tin. (3.) This poisonous amalgam must be abandoned. (4.) Exemplary damages, "at the discretion of the jury," will be sustained by the courts for this reckless tampering with human life in using a dangerous means when a safe one could be used. (5.) The canners have only themselves to thank for the present panic in their business, for they have persisted in this dangerous plan, knowing it was dangerous. (6.) Every cap should be examined, and if two holes are found in it send the can at once to the Health Board, with the contents, and name of the grocer who sold it. (7.) Reject every article of canned food that does not show the line of rosin around the edge of the solder of the cap, the same as is seen on the seam at the side of the can. (8.) Reject every can that does not have the name of the manufacturer or firm upon it as well as the name of the company and the town where manufactured; "standards" have all this. When the wholesale dealer is ashamed to have his name on the goods fight shy of them. (9.) Press up the bottom of the can; if decomposition is commencing, the tin will rattle the same as the bottom of the oiler of your sewing machine does. If the goods are sound it will be solid, and there will be no rattle to the tin. (10.) Reject every can that shows any rust around the cap on the inside of the head of the can. If housewives are educated to these points then muriate of zinc amalgam will become a thing of the past, and dealers in "swells" have to seek some other occupation.

THE CROW AND THE COUNTRY DOCTOR.

(A MEDICAL FABLE.)

A FLOCK of Crows was much alarmed one day at the sight of a strange object in the midst of a field upon which they customarily fed. They at once called upon an Old Crow who practiced his profession in those parts, and who made a specialty of corns, to give his opinion about the matter. The Crow, having examined the object, shook his head, and said that it was a serious case, and that it was lucky he had been summoned so soon, though he should have been called earlier, and he would like the advice of his friend, the Owl, who had had the benefit of travel abroad, and who was particularly skillful in cases which called for the Steady Use of the Eyes. He would also like to have the Frog, who was spending his summer vacation by a neighboring pool, and who had a wide reputation for his physiological knowledge, to see the case. The Crow, the Owl, and the Frog, met, and having studied the object at a suitable distance withdrew to the shade of a High Wall in order to deliberate. The Frog first opened his mouth, and observed that it was a nice Case, which reminded him of a very curious experience that he had had with a piece of Red Flannel two summers before, when he received a severe contusion upon the centre of Goltz. After telling all about this very apposite event, the Owl observed that such cases were extremely rare. He had, however, had two very much like them, the details of which he had forgotten. He then related some very humorous obstetrical stories, which much amused the Crow.

Having received these opinions, the Crow thanked his Colleagues for the valuable light they had furnished. He had himself been at first disposed to think the trouble a case of *Terror Corvorum*, or Scare-Crow;

but the advice given reminded him now that the appearance in the cornfield exactly resembled a country doctor whom he occasionally met, and who, after practicing medicine for forty years, was at present trying to live on What he had Saved.

This diagnosis was finally agreed upon, and reported to the anxious Crows outside, who were much relieved.

MORAL. This story shows the profit that is got from consultation, and the lucrative nature of the practice of medicine.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 1, 1884.

Deaths reported 1706: under five years of age, 578; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 386, consumption 268, lung diseases 184, diphtheria and croup 149, diarrhœal diseases 105, typhoid fever 53, scarlet fever 22, malarial fevers 16, whooping-cough 14, measles 13, cerebro-spinal meningitis nine, erysipelas three, puerperal fever two. From *scarlet fever*, Philadelphia, Boston, and St. Louis four each, District of Columbia three, Woburn two, New York, Holyoke, Salem, Newburyport, and Bradford one each. From *malarial fevers*, New York nine, St. Louis six, Charlestou one. From *whooping-cough*, New York six, Boston five, District of Columbia three. From *measles*, New York nine, Fall River three, Philadelphia, one. From *cerebro-spinal meningitis*, Fall River three, New York, Philadelphia, St. Louis, District of Columbia, Lowell, and Holyoke one each. From *erysipelas*, Boston two, Fall River one. From *puerperal fever*, New York and Boston one each.

Cases reported in Boston: typhoid fever 57, scarlet fever 55, diphtheria 36, and measles 18.

In 93 cities and towns of Massachusetts, with an estimated population of 1,167,683 (estimated population of the State 1,955,104), the total death-rate for the week was 17.72 against 17.70 and 17.62 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending October 25th, the death-rate was 20.9. Deaths reported 3517: infants under one year of age 869; acute diseases of the respiratory organs (London) 274, diarrhœa 105, scarlet fever 67, measles 55, fever 66, whooping-cough 46, diphtheria 32, small-pox (London 15, Liverpool, Hull, Birmingham, and Wolverhampton one each) 19. The death-rates ranged from 16.5 in Sunderland to 31.5 in Preston; Birmingham 20.9; Birkenhead 18.4; Bradford 20.4; Leeds 24.9; Leicester 20.4; Liverpool 26.4; London 19.0; Manchester 26.1; Nottingham 22.4; Sheffield 20.3. In Edinburgh 17.6; Glasgow 25.1; Dublin 26.8.

For the week ending October 18th, in the Swiss cities, there were 36 deaths from consumption, diarrhœal diseases 28, lung diseases 12, diphtheria and croup five, whooping-cough two, typhoid fever one, small-pox one. The death-rates were, at Geneva 8.2; Zurich 7.9; Basle 11.6; Berne 33.3.

The meteorological record for the week ending November 1st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date. Oct.–Nov., 1884.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM NOVEMBER 1, 1884, TO NOVEMBER 7, 1884.

SPENCER, W. C., major and surgeon. Ordered to Fort Trumbull, Conn., for duty as post surgeon, relieving assistant surgeon William J. Wilson, U. S. A., who will report at Department Headquarters, and await further orders. S. O. 227, Department of East, November 5, 1884.

TOWN, F. L., major and surgeon. Assigned to temporary duty as post surgeon, Fort Clark, Texas. S. O. 145, Department of Texas, October 27, 1884.

BENTLEY, EDWIN, major and surgeon. To be relieved from duty at Fort Clark, Texas. S. O. 145, Department of Texas, October 27, 1884.

CORBUSIER, W. H., captain and assistant surgeon. Ordered to Fort Grant, A. T., for duty as post surgeon. S. O. 102, Department of Arizona, October 30, 1884.

HOPKINS, WM. E., first lieutenant and assistant surgeon. Ordered to Fort Lowell, A. T., for duty as post surgeon. S. O. 102, Department of Arizona, October 30, 1884.

EGAN, PETER R., first lieutenant and assistant surgeon. Relieved from duty at Fort Lowell, A. T., and ordered to Fort Bowie, A. T., for duty as post surgeon. S. O. 102, Department of Arizona, October 30, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING NOVEMBER 8, 1884.

CRAIG, THOMAS C., passed assistant surgeon. To the Alliance, for temporary duty. November 1, 1884.

SWAN, ROBERT, passed assistant surgeon. Detached from the Naval Hospital, Norfolk, Va., and placed on sick leave. November 3, 1884.

WIEBER, F. W. F. Appointed assistant surgeon. November 3, 1884.

SUFFOLK DISTRICT MEDICAL SOCIETY. *Obstetric and Gynæcological Section.* — There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, November 19th, at 7.45 o'clock. Communications: Dr. Stephen W. Driver, of Cambridge, will, by invitation, read a paper entitled An Analysis of One Thousand Successive Obstetrical Cases. Following which Dr. Royal Whitman will report A Case of Placenta Prævia; Delivery by Version. It is especially urged upon all members of the Suffolk District Medical Society, whether members of this particular Section or not, to attend these meetings, take part in the discussions, and help to make the section a Success. All members of the Massachusetts Medical Society will be welcome at any of the meetings of the Section, and are invited to take part in the discussions.

JAMES R. CHADWICK, M. D., *Chairman.*
ROBERT B. DIXON, M. D., *Secretary.*

THE NITRITE OF AMYL AS AN ANTIDOTE IN STRYCHNIA POISONING.

BY HOBART A. HARE, M. D., PHILADELPHIA, PA.

In 1871 Dr. St. Clair Gray, of England, made several experiments to determine whether the nitrite of amyl was practically as efficient an antidote to strychnia in toxic doses as its physiological action would indicate. In his experiments he used but two rabbits, and his results were very satisfactory. He gave to each rabbit ten drops of the nitrite of amyl and one half grain of strychnia. Both drugs were given simultaneously and by the hypodermic method, and no decided symptoms were manifested. He found, however, that one quarter grain of strychnia frequently caused death in one convulsion when given alone. The writer has used six rabbits, as may be seen further on, but has not been able to come to such satisfactory results as Dr. Gray.

To rabbit No. 1 he gave one eighth of a grain of strychnia, and in two minutes a severe convulsion came on during inspiration, and by using artificial respiration and inhalations of the nitrite the animal's life was saved. This occurred five times. The sixth convulsion came on during expiration, and therefore no ordinary artificial respiration could be induced, and the animal died. (It is proper to state here that none of the nitrite was given hypodermically.) M. Schiff has tried the effects of artificial respiration[1] in strychnia poisoning with very satisfactory results, but in his experiments he overcame the difficulty of carrying on artificial respiration when the convulsion came on in expiration by inserting a canula into the trachea and carrying on the renewal of air by forcing air into the lungs. That such a proceeding would be entirely impractical in the human being is so evident that it is hardly necessary to mention it in this paper.

It is very evident to any one if death is caused in strychnia poisoning by spasmodic locking of the chest walls, that artificial respiration, thereby causing air to enter the lungs, will prolong life. It is equally evident that such means could only be of service when the convulsion came on in inspiration, as pressure could then drive out the exhausted air and the lungs be filled by the natural expansion of the chest walls due to their innate elasticity. In expiration the chest would be locked when its walls were most nearly approximated, giving no room for air in the first place, and preventing any external force from doing good, while internal force could not be used. That the nitrite of amyl is capable of stopping a convulsion when inhaled is certain. In each convulsion in the rabbit just mentioned complete relaxation came on as soon as the rag wet with the nitrite was held to the nostrils of the animal, and the full effect of the nitrite was seen by the rapid breathing, injection of the conjunctiva, and the relaxation before mentioned. When the nitrite was removed, and as soon as its after effects were over, the convulsions returned, and so on through the five till the sixth caused death in the manner stated.

In the second rabbit, to which was given one twentieth of a grain of strychnia followed in four minutes by fifteen minims of the nitrite of amyl, a partial convulsion came on one minute after the nitrite was given. After this the animal hopped about the floor as if free from any poison whatsoever, with the exception that the slightest touch would cause a tonic spasm of the whole body of about one second's duration. Five minutes later slight convulsion, followed in thirty seconds by spasms which followed each other with great rapidity and regularity. This lasted for fifteen minutes. A period of complete relaxation now came on with the respirations at about 130 per minute; following this in three minutes came irregular spasms. These spasms became less and less frequent, and at last only came when the animal was disturbed. All along during these latter spasms there was constant tonic spasm of the hind legs, and it was clear that the effects of the more volatile nitrite were wearing off, and that the strychnia was beginning to reassert itself. This was the more clearly shown by the fact that the spasms increased both in frequency and force. Forty-five minutes after the injection of the strychnia a convulsion came on, from which the animal partially recovered, and this was succeeded by another and then another, in which last convulsion the animal died, it being fifty minutes after the injection of strychnia.

In rabbit No. 3 one twentieth grain of strychnia was given, which caused death in less than two minutes. As soon as the convulsion came on artificial respiration was used, nitrite of amyl held to the nose, and twenty drops of the nitrite given hypodermically; this animal died without being relaxed.

The difference in time between the dose of strychnia and the first convulsion, and also between the first convulsion and fatal effect in the last two rabbits, can, I think, be explained.

In the last rabbit (No. 3) the hypodermic of strychnia was given very near to the vertebræ, and was probably taken, in part at least, directly to the cord by the intervertebral vessels.

In the preceding rabbit (No. 2) the hypodermic of strychnia was given nearer the abdomen, and the nitrite was given near the cord, and so its effects were present when the excito-motor reached the cord in full force.

To rabbit No. 4 one twentieth grain of strychnia[2] and nineteen minims of nitrite of amyl were given simultaneously in this respect, being the counterpart of Dr. Gray's experiments. In three and one half minutes a severe convulsion came on, which was followed by eight lesser convulsions, occurring at irregular intervals, but following each other rapidly. The convulsions now became further apart, but individually more prolonged, the longest time between any two convulsions being thirteen minutes. This interval began forty-five minutes after the first convulsion. One hour after injection several spasms came on, succeeding each other with great rapidity. These lasted for the next thirty minutes. The respiration was noticed not to be as seriously retarded as formerly for a short time, but this change for the better was only transient; in a short time several convulsions came on, in the last one of which the animal died.

Rabbit No. 5 was given the same amount of strychnia as its predecessor, and the same amount of the nitrite, about one inch from the vertebræ, and both

[1] Schmidt's Jahrbücher, Bd. cxli., p. 43.

[2] It is proper to state that the strychnia was given near the cord in this case also.

drugs were given simultaneously. A convulsion came on in two and one half minutes, which was followed by almost constant spasms and convulsions with no intervals of rest at all. This animal died twenty-eight minutes after injection, apparently from exhaustion, as there was no spasm or convulsion at the time of death, and no symptoms of the presence of the nitrite, at least in overdose.

Rabbit No. 6. Strychnia, one twentieth of a grain, and nitrite of amyl, nineteen minims, were given as before. Convulsion came on in nine minutes, the delay being probably due to the fact that quite a large amount of blood escaped after the hypodermic needle was withdrawn, and with the blood escaped quite a quantity, probably, of the injected and as yet unabsorbed fluid. This animal lived about three hours, during which time it had numerous convulsions and spasms. This increase of time before death may be attributed to the hæmorrhage above stated.

It is evident from the foregoing accounts that —

First. Nitrite of amyl does prolong life in strychnia poisoning, although its action is so fleeting compared to that of its adversary that it can only be used to tide over the patient until more persistent remedies or antidotes, such as potassium bromide or chloral, can be administered.

Second. That it cannot be used by inhalation as an antidote with any chance of security from a fatal termination, owing to the facts regarding expiration before stated.

Third. That the longer the nitrite be given after the strychnia the less good it will do, *provided* the strychnia has already shown itself by convulsions or otherwise. This is true not because the nitrite is less powerful after the first convulsion, but because death is more apt to come before nitrite can fully act.

Fourth. That the nitrite has to be given in such quantities and at such times that its full physiological action be present constantly, otherwise in the instant which may supervene between the after effects of one dose and the beginning of the next the patient may die.

Fifth. That in cases of strychnia poisoning, the nitrite of amyl being used as an antidote, an injection of the nitrite should be given, and the patient kept moderately under its influence by inhalations until other remedies are obtainable.

The writer cannot account for the disparity existing between the results of Dr. St. Clair Gray and his own. It is certain that one twentieth grain of strychnia invariably causes death in the rabbit, as the foregoing experiments would prove. It is probable that some mistake must exist as to the amount of Dr. Gray's doses from errors of a typographical character or from impurity of the strychnia used. His doses, as before stated, were one half grain to ten drops of nitrite, and that he found one quarter grain often caused death, when given alone, in one convulsion. That one quarter grain of strychnia should cause death in a rabbit in one convulsion cannot be wondered at when we consider that a twentieth grain is a maximum dose for a man for continuous use. Many deaths are recorded from one quarter and one half grain doses in man. One man who took one half of a grain was dead in twenty minutes.

It may be well to state that the strychnia used by the writer was very carefully selected, as was also the nitrite of amyl.

LATENT ACUTE PERITONITIS OF IDIOPATHIC ORIGIN. LARGE AMOUNT OF PUS IN THE ABDOMINAL CAVITY. EVACUATION. RECOVERY.[1]

BY Z. B. ADAMS, M. D., FRAMINGHAM, MASS.

"L'on peut dire avec vérité que le pus est la secrétion normale du péritoine enflammé." — *Nouveau Dict. de Med. et de Chirurgie*, Article "Péritonite Aiguë."

FRANCES L., four and a half years old. Parents and grandparents all living and healthy. The fourth of five children. No family history of disease of any kind.

Previous history. Two weeks before birth, for no obvious reason, the mother felt something break suddenly, and a large quantity of liquor amnii was discharged. At that time all feeling of motion ceased. The labor was at full term, easy and rapid. The child was very feeble, scarcely breathed, and was estimated to weigh not more than four pounds. She looked like a seven months' child. There was a firm knot in the cord. For the first week the child was kept alive by artificial heat, and was apparently too weak to nurse. At the end of that time she began to gain. Livid ecchymoses appeared upon the buttocks and bowels.

The child throve, and at the date of sickness was forty-one inches high and well nourished, but not fat. Her digestion was more liable to disturbance than that of the other children.

When about eight months old she was tipped out of her carriage and fell a few feet off a bank, was picked up insensible, but soon recovered. She became very pale and vomited from the shock.

On the 17th of May, 1884, after a somewhat hearty dinner, Frances complained of feeling ill, was nauseated, feverish, and languid. The night was restless, and she had several loose stools with pain in bowels. Seen by me the morning after, the face was flushed, temperature 104° F., pulse 120, nausea, diarrhœa, no tenderness of bowels, no pain, no tympanites. Complained only of feeling tired. The parents feared scarlatina or diphtheria. At night the temperature was 105° F., pulse 140; she was rather restless, but did not complain of pain. The symptoms were attributed by me to indigestion.

On the next day, May 19th, the youngest child was attacked with similar symptoms, which, however, soon disappeared.

Frances continued to have diarrhœa for about a week. The stools were slimy, containing mucus. The nausea gradually subsided, as did the fever, but she did not recover. She made no complaint of pain and there waa no tenderness of the abdomen. She remained languid, did not care to get up, had a pulse of 120, and a temperature occasionally rising to 102° F. in the evening, but not above 100° F. in the day. There was no marked tympanites, but rather dullness of the abdomen. The appetite did not return. The skin was dry and the expression one of indifference. The symptoms were of a mild typhoid character. There was no hectic, no headache, nor sweating. Sleep not disturbed and mind perfectly clear, but not interested in anything. The stools became scanty and occasionally mucous in character. It was supposed by me that there was some bowel obstruction. The most careful examination revealed no tenderness anywhere and no tumor. The

[1] Read before the Middlesex South District Medical Society, October, 1884.

form of the belly was not unusual, but there was some general distention, and there was dullness on percussion in spots. The symptoms did not warrant the diagnosis of peritonitis, either tubercular or from other causes. There was no colic pain, no tenderness on pressure, no fluctuation, no enlarged glands. There was no complaint of tenesmus. The tongue was moist and coated.

This condition continued for about three weeks, during which time the abdomen very slowly enlarged.

At the beginning of the fourth week a nodulated tumor appeared in the epigastrium, occupying a right median position. It was somewhat tender to the touch, and could be plainly seen. The abdomen was now very much distended, showing enlarged veins. There was no pain, and no tenderness on pressure except over tumor. The renal region was resonant and the abdomen also in spots, but generally dull on percussion. The diaphragm and thoracic organs were pushed up, and the apex beat of the heart was an inch above the nipple line. There was emaciation, but no decided hectic nor sweating. Appetite was absent, and there was frequent complaint of nausea after taking food. The abdomen presented a uniform enlargement, which was not elastic nor œdematous. Fluctuation was not clear, nor was there a marked line of flatness anywhere.

She was now seen by Dr. H. O. Marcy, of Boston, in consultation, and it was decided to aspirate. The needle, introduced above the pubes, drew off more than a pint of pure, creamy, odorless pus. Dr. Marcy very kindly examined and reported upon this matter, which he found to contain multitudes of micrococci, pus corpuscles often disintegrated, fine granules, a little free fat, and fine oil globules. "The micrococci very active, which reproduced in pairs, not chains."

There was temporary relief to the general symptoms, and ten days afterwards, precisely six weeks from the onset of the disease, with the valuable aid of Dr. Marcy, and of Drs. Smith and Bigelow, of Framingham, I made a section two inches long and above the umbilicus as far as the tumor already described in the epigastrium. This tumor was then about as large as a silver dollar, nodulated, flattened, and fluctuating in the middle, slightly blushed, and sensitive to the touch. The condition of the child was as follows: Respiration of the costal type; thoracic viscera pushed upwards; apex beat of heart one inch above the nipple line; emaciation marked over the ribs; large veins prominent on each side of the abdomen; umbilicus prominent; face dusky and anæmic; no jaundice; thrilling in jugulars; countenance not expressive of pain; abdomen not tender; color of skin somewhat dusky; no œdema; urine normal. Pulse 140; temperature 101° F.

A careful section was made through the skin and subcutaneous layers, and the peritonæum was opened with the usual precautions. A quantity of odorless, creamy pus, estimated to amount to considerably more than a quart, flowed out, together with some blood-clots and masses of fibrinous material, as soon as the peritoneal cavity was opened. The peritonæum appeared thickened, deep red in color, and bled wherever touched. Firm bands of adhesion were found, especially on the right side. The nodulated tumor had no deep origin or connection, and proved to be only inflammatory thickening of the peritonæum itself and the subcutaneous cellular tissue; evidently an effort of nature to get rid of the pus. At my request Dr. Marcy gave me his valuable aid in exploring the cavity, and confirmed my observations. The peritoneal cavity was then thoroughly irrigated with hot water (1 — 200 carbolic), further examination or interference being prevented by the condition of the patient. Collapse from shock and the withdrawal of so large an amount of fluid pressure from the intestinal tract, obliged us to stop and resort to artificial respiration, and to close the wound as rapidly as possible. This was done with two deep sutures, taking in the peritonæum and fine superficial suture of the skin.

Immediately after the operation the temperature fell to normal, and the pulse to 104, and so remained for four days. There was no pain, she slept well, and had a good appetite; urine normal.

On the fourth day after operation the temperature dropped to 97° F., and there was appearance of exhaustion, with loss of appetite; pulse 120, and an evening rise of temperature to 102° F. The temper became restless and capricious, and the abdomen showed evident signs of reaccumulation of fluid. The wound was healthy. Some tympanites developed. The superficial sutures were removed on account of the stretching.

Fifth day. Abdomen very tense. Deep stitches were removed in hope of giving exit to pus, but union had taken place and only a few drops appeared at the points of suture. Morning temperature normal, evening 102° F. to 103° F. No chills, sweating, nor headache. The bowels moved with discharge of gas and some relief to distention. Urine normal.

Seventh day. Union of abdominal wound complete. Some tympanites. Considerable distention and uneasiness. On the eighth, ninth, and tenth the evening temperature rose to 103° F., and in the morning fell to subnormal, — 97.5° F.

Twelfth day. Abdomen tense, twenty-two inches. A spontaneous opening occurred over the tumor in epigastrium with free discharge of a thin purulent matter, and relief to all the symptoms. The temperature fell to 96.5° F. and remained subnormal for four days. On the fourteenth day the discharge ceased, and there was occasional vomiting. The abdomen was soft, and measured eighteen inches. Appetite fair. Pulse feeble (104) and intermittent. Urine scanty. Slight discharge of pus from epigastric opening in the evening.

Sixteenth day. Temperature rose to 102° F. between noon and three P. M., and remained high until eight P. M. After passing large quantities of flatus and some fæces by use of injections, the temperature slowly fell, and a slight discharge took place from the opening. The child was drowsy all day.

After this date all discharge ceased. The nodulated tumor in the epigastrium softened and disappeared. On the thirtieth day the heart had completely returned to its normal situation. The child regained appetite and color. During all this time the bowels were kept free by daily injections, usually of simple warm water, but occasionally turpentine or oil was added.

The pus seemed to gravitate towards the region of the spleen, and thence to the left iliac region, where there still remains some dullness. Two or three times at considerable intervals there have been sharp attacks of colic pain during this convalescence; once apparently caused by a blow upon the stomach, and once by some error in diet. During these colic attacks the abdomen balloons out over the site of the epigastric tumor and that of the incision made at the operation. Ordinarily there is nothing remarkable about the ab-

domen except, perhaps, that it is somewhat fuller than usual along the median line. There is no tenderness and no tympany or dullness anywhere. Color of skin normal. The bowels move without pain; are seldom constipated; urine normal; and the child has grown an inch and a half in height, and has gained nearly ten pounds in weight in about three months.

THE PATHOLOGY OF BRONCHO-PNEUMONIA.[1]

BY FRANCIS DELAFIELD, M. D.,

Professor of Pathology and Practical Medicine in the College of Physicians and Surgeons, New York.

I SHALL offer for your consideration, this evening, some observations on the subject of broncho-pneumonia. I venture to do this for the reason that I believe that this particular lesion suffers from the effects of tradition, from having been called catarrhal pneumonia, and from its relations to pulmonary phthisis. It is also doubtful whether the profession appreciate what a common lesion it is.

I do not mean that the real lesions and symptoms of the disease have not been described. They have been described by different observers; but their descriptions have been, for the most part, fragmentary, and have failed to give a picture of the disease.

The current notions concerning the disease have remained somewhat obscure and indefinite. The prevailing ideas concerning broncho-pneumonia may be stated as follows: —

That the terms broncho-pneumonia, lobular pneumonia, catarrhal pneumonia, and capillary bronchitis may all be used to designate the same lesion: although it is customary to use the words broncho-pneumonia and lobular pneumonia when the disease occurs in children; capillary bronchitis when it occurs in adults; and catarrhal pneumonia when it is believed to be a form of phthisis.

That the inflammation begins in the bronchi, extends to the small and capillary tubes, and then to the groups of air vesicles which belong to these bronchi, and that for this reason the hepatization assumes a lobular form.

That obstruction of the bronchi with inflammatory products frequently produces areas of atelectasis.

That the catarrh may become chronic, the products of inflammation in the air vesicles undergo cheesy degeneration, interstitial changes be developed in the frame-work of the lung and so a form of pulmonary phthisis be produced.

This, I think, is a fair enough example of the ordinary accounts of broncho-pneumonia — accounts which fail to bring out the essential features of the disease.

Let us, then, turn to the conditions themselves — to the clinical symptoms and the lesions of broncho-pneumonia as we all can see them for ourselves.

To approach the subject properly, we must consider the symptoms and lesions of acute bronchitis as well as those of broncho-pneumonia.

First, then, of *acute catarrhal bronchitis*. This is a disease of very common occurrence, especially in children, but one which seldom proves fatal. Our knowledge of its lesions is derived from exceptionally severe cases, from cases which are complicated by other diseases, and from the symptoms which we observe during life.

The inflammation involves regularly the trachea and the larger bronchi, less frequently the smaller bronchi also. As a rule the bronchi in both lungs are equally affected.

The first change seems to consist in a congestion and swelling of the mucous membrane of the bronchi with an arrest of the functions of their mucous glands. This is attended with pain over the chest, a feeling of oppression, rapid or asthmatic breathing, and a dry cough.

Fever and prostration are present in a degree corresponding to the extent and severity of the inflammation and to the age of the patient.

After this the mucous glands resume their functions with increased activity, the congestion and swelling diminish, there is a more rapid desquamation of the superficial epithelial cells, an increased growth of the deeper epithelial cells, and a moderate emigration of white blood cells. Sometimes the red blood cells also escape from the vessels.

The patient now has less pain and oppression, the cough is accompanied with an expectoration of mucus, mixed with epithelium, pus, and sometimes blood. After death the only lesions visible are the increased quantity of mucus, the growth of new epithelium, a few pus cells infiltrating the stroma of the mucous membrane, and sometimes a general congestion. If the smaller bronchi are involved they contain pus cells.

In a moderate number of cases, especially in very young children, certain accessory lesions are added. There may be a general congestion of the parenchyma of the lung, and even a filling of some of the air vesicles with inflammatory products. Still further, the filling of the small bronchi may lead to the collapse of the groups of air vesicles to which they lead, and thus are produced areas of atelectasis, which may be further changed by inflammatory processes.

In acute catarrhal bronchitis, then, the inflammation involves regularly only the mucous membrane of the bronchi; and in this mucous membrane the only changes are: congestion, swelling, changes in the epithelial cells, and in the functions of the mucous glands.

As complicating conditions, we may find atelectasis, congestion of the parenchyma, and areas of diffuse pneumonia.

Now let us consider the lesions and symptoms of broncho-pneumonia.

This disease is of common occurrence in children as an idiopathic inflammation, and as a complication of measles, whooping-cough, scarlet fever, and diphtheria. In adults it occurs less frequently, but in them also it may be idiopathic, may complicate the infectious diseases, and may follow injuries of the brain and spinal cord. Constitutional syphilis also may give rise to broncho-pneumonia, and in pulmonary phthisis this same inflammation constitutes an important part of the lesions.

In children, while the inflammation always presents the same essential characters, yet there is considerable diversity, both in the symptoms and in the lesions, in different cases. Thus, in infants a few weeks old, often the only symptoms are rapid breathing, a febrile movement, prostration, and death.

In older children there are well-marked constitu-

[1] Read before the Pathological Society of Philadelphia, October 23, 1884.

tional disturbances — fever, prostration, and cerebral symptoms; in some cases the cerebral symptoms being excessively developed. The breathing is rapid. There may be cough. The physical signs are those of bronchitis alone, or of bronchitis with consolidation of the lung. If there is consolidation it is developed slowly, and disappears slowly. Not infrequently successive portions of the lung become consolidated. The disease terminates in the death of the patient, in recovery, or it assumes a chronic character. This disposition of the broncho-pneumonia to become chronic is one of its characteristic features, a feature in which it differs from acute bronchitis and lobar pneumonia. The cases vary, however, as to the degree in which the disposition is carried out.

In some children the disease after running its regular course of one or two weeks subsides, the constitutional symptoms are less marked, the child seems better in every way. But yet the physical signs of consolidation continue, there is still a slight rise of temperature, and convalescence does not fairly begin. In this condition the child may remain for a number of weeks and then get entirely well, except that the percussion note and the breathing remain somewhat changed.

In many such cases as these the recovery is permanent and the child has no further trouble. But in other cases, after the lapse of several months, the child is attacked with acute general tuberculosis. Thus it is not uncommon in children's asylums for an epidemic of measles complicated with broncho-pneumonia to be followed after the lapse of a year by an epidemic of acute tuberculosis.

In other children the course of the disease is more protracted. The physical signs of consolidation continue, there is a febrile movement, the child has no appetite, it gradually emaciates, and dies at the end of several months. These cases resemble pulmonary phthisis in their symptoms, but they are really only examples of a broncho-pneumonia which has become chronic.

In still other children the physical signs and the constitutional disturbances continue, but the child does not succumb to the disease. It continues to live with the evidences of a chronic bronchitis which go on year after year. So the child may grow up to adult life, sometimes better, sometimes worse, never entirely well. Cough, expectoration, dyspnœa, occasional fever harass the patient at intervals. The lung becomes more and more solid, the bronchi more dilated, the pleura thicker, and the affected side of the chest more retracted.

In the cases of acute broncho-pneumonia which die within from two days to three weeks there is some variety in *the post-mortem appearances*.

The lungs may be large and well aerated, but on section the cut ends of the medium-sized and smaller bronchi are unusually prominent and thick, and around them are little zones of hepatization of red, or gray, or white color. This appearance of the lung may be further modified by a cylindrical dilatation of the thickened bronchi.

In other cases the lungs are denser and more congested, and a larger or smaller portion of them is consolidated. The consolidation portions are unaerated, dense, and smooth, of red color, or pinkish gray, or dark red. Or the color may be mottled, — small, rounded gray or whitish areas surrounded by red hepatization.

The distribution and extent of the consolidation also vary. The hepatized areas may be small, encircling the bronchi, and situated at some distance from each other. Or they may in some one lobe or part of a lobe be close together, and between them is a more diffuse hepatization so that this part of the lung may be completely solid.

The appearance of the consolidated lung may be further changed by a cylindrical dilatation of the bronchi.

In still other cases the consolidated portions of lung are of some size and of somewhat regular shape, as if they were portions of lung corresponding to bronchi. These portions are dense, unaerated, of dark-red color, and somewhat shrunken.

If the inflammation has become chronic, then over one lobe or part of a lobe the pleura is thickened, bands of fibrous tissue run into the substance of the lung, and the lung tissue is dense, hard, and unaerated.

When we examine these lungs more minutely we notice first some peculiarities which belong to them because they are the lungs of children and not of adults. The bronchi and the connective tissue framework of the lungs occupy a larger relative space than they do in the lungs of adults; and in any inflammation of the lungs they are apt to take a more prominent share. The air vesicles are small, and products of inflammation which have been formed within them are absorbed slowly and with difficulty. The walls of the vesicles are lined with a nearly continuous layer of epithelial cells. When the vesicles are inflamed there is a greater production of new epithelium and a less of fibrine than in adult lungs. The small size of the air vesicles render a simple congestion and dilatation of the capillary vessels within their walls a more serious condition than it is in adults. The bronchial glands are more regularly and intensely inflamed. These peculiarities of the child's lung seem to account for its liability to certain forms of inflammation.

The same exciting causes apparently produce in a child under five years of age broncho-pneumonia; in a person between the age of five and fifteen broncho-pneumonia or lobar pneumonia; in an adult lobar pneumonia.

Now let us consider more in detail the lesions of broncho-pneumonia in children.

The trachea and large bronchi are congested and coated with mucus, as in acute bronchitis; but in the smaller, and to a less extent in the capillary bronchi, the changes are of a different character. In these small bronchi the entire thickness of their walls is infiltrated with cells, — partly new connective tissue cells, partly pus cells. This change may affect the small bronchi equally in all parts of the lungs, or it may be confined to those situated in one lobe or part of a lobe.

Around every bronchus, of which the walls are infiltrated with cells in this way, is a zone, either of intense congestion or of pneumonia, the inflammation extending directly outwards from the bronchus to the surrounding vesicles.

In the zones of peribronchitic pneumonia the walls of the air vesicles are infiltrated with cells in the same way as are those of the bronchi. The cavities of the vesicles are filled with pus and epithelium, or with an organized tissue composed of a basement substance and cells.

These constitute the essential features of the lesion,

— a bronchitis which involves the *walls* of the bronchi, and a pneumonia which involves the vesicles *surrounding* the bronchi, and which produces changes in the *walls* of the vesicles as well as in their cavities, while the inflammatory products within the cavities of the vesicles are not only pus and fibrine, but also organized tissue.

To these essential lesions are often added other accessory changes. The bronchi, of which the walls are infiltrated with cells, may be dilated. Between the zones of peribronchitic pneumonia the lung is congested, and there may be areas of diffuse red hepatization, which do not, however, correspond to bronchi. There is often a layer of fibrine on the pulmonary pleura. There may be areas of atelectasis corresponding to obstructed bronchi.

The bronchial glands are swollen, and the seat either of simple or of tubercular inflammation.

When the broncho-pneumonia passes into the chronic condition the inflammation usually persists only in part of a lobe, or a single lobe, while the rest of the lungs return to a normal condition. In that portion of the lung in which the inflammation persists we find the small bronchi with their thickened walls and their zones of peribronchitic pneumonia. The number of bronchi involved may be moderate, and then a section of the lung will look as if it were studded with fibrous nodules. Or most of the bronchi may be involved, the zones of peribronchitic pneumonia are close together, and the entire lung tissue is dense and solid. In either case the bronchi may be dilated and the pulmonary pleura thickened. As the inflammation goes on its interstitial character becomes more and more marked, until the affected portion of lung becomes converted into a mass of fibrous tissue, in which the bronchi still remain, while the air vesicles are obliterated. The blood-vessels, however, are for the most part not obliterated, so that the lung does not become necrotic or degenerated. Still occasionally areas of cheesy degeneration exist.

These are the characteristic features, then, of the broncho-pneumonia of children.

In adults broncho-pneumonia occurs in one of four forms: As an idiopathic inflammation of acute and severe type. As a subacute inflammation. As a complication of the infectious diseases and of lesions of the brain and spinal cord. As one of the lesions of phthisis.

(1.) *The acute, idiopathic broncho-pneumonia of adults.*

The invasion of this disease is acute and severe.

The patients have rigors; pains in the head, back, and chest; vomiting and marked prostration. The temperature runs between 102° F. and 105° F.; the pulse is rapid; the breathing is rapid and unsatisfactory. There is cough, at first dry, later accompanied by profuse muco-purulent and bloody expectoration. There is venous congestion of the skin, albumen in the urine, and cerebral symptoms. When we examine the chest we find the percussion note normal, or exaggerated, or dull. There are crepitant, subcrepitant, and coarse râles with sibilant and sonorous breathing.

The cases usually terminate fatally in about seven days. After death we find both lungs large, heavy, and congested. There is fibrine on the pulmonary pleura. The trachea and large bronchi are congested and coated with mucus. The smaller bronchi contain pus, their walls are thickened and infiltrated with cells, and around them are zones of air vesicles with their blood-vessels gorged with blood, and in their cavities epithelium pus and fibrin.

(2.) *The subacute broncho-pneumonia of adults.* This is a rare disease. It has a clinical history much resembling that of acute phthisis.

The patients are attacked with prostration, fever, cough, and muco-purulent expectoration, dyspnœa, pain in the chest, coarse râles all over the chest, with dullness over the consolidated portion of the lung. These symptoms continue, the patients lose flesh and strength, and die at the end of several weeks.

After death we find fibrine on the pulmonary pleura. The larger bronchi are congested and coated with mucus. There is an irregular, diffuse red hepatization mottled with small white nodules from the size of a pin's head to that of a pea. In the diffuse red hepatization the air vesicles are filled with pus, epithelium, and fibrine. The white nodules correspond to sections of bronchi with zones of peribronchitic pneumonia. These bronchi are of small size, they contain pus, their walls are thickened and infiltrated with cells, and they may be dilated.

In the peribronchitic zones of pneumonia the walls of the vesicles are thickened and infiltrated with cells, but the blood-vessels remain pervious and can be injected. The cavities of the vesicles are filled not with pus and fibrine alone, but also with a basement substance of homogeneous or finely fibrillated character, in which are imbedded polygonal, round, and fusiform cells.

(3.) *The complicating broncho-pneumonia of adults.* It is not uncommon for some of the infectious diseases, and some of the lesions of the brain and spinal cord to be accompanied by the development of this form of inflammation of the lung.

In typhoid fever we sometimes find a broncho-pneumonia exactly resembling the same lesion as it ordinarily occurs in children.

In pyæmia the inflammation is of the same kind, but is apt to be less extensive, involving only part of one or both lungs.

With lesions of the brain and spinal cord the changes are the same as with pyæmia.

(4.) *With phthisis,* both acute and chronic, broncho-pneumonia often forms an important part of the morbid changes in the lungs, but yet it is never the primary or the only lesion. It is only one of a number of pathological changes which go to make up the complex whole of pulmonary phthisis.

From what has been said, then, I would draw the following conclusions: —

There is a form of inflammation of the lung which may properly be called broncho-pneumonia.

In children it is the most frequent form of pneumonia, in adults it is less common.

It differs from bronchitis and from lobar pneumonia in that the inflammation effects changes in the *walls* of the bronchi and of the air vesicles, and this peculiar interstitial character of the process exists from the very outset.

The inflammation extends from the bronchi, not to the group of air vesicles into which they lead, but directly outwards to the vesicles which surround the inflamed bronchi, and in these vesicles the walls are changed.

The interstitial character of the inflammation is its most important feature. It accounts for the severity

of the symptoms, the frequent long continuance of the consolidation, the dilatation of the bronchi, and for the tendency of the broncho-pneumonia to assume a chronic character.

The complicating tubercular inflammation of the bronchial glands may give rise later to general tuberculosis.

Broncho-pneumonia is not a form of phthisis; it is doubtful if it is ever directly followed by phthisis; but it constitutes a part, and often an important one, of the lesions which constitute phthisis.

I have endeavored to describe in a somewhat incomplete way the characteristic symptoms and lesions of an ordinary disease. I am well aware that I have described conditions which are familiar, and that nothing which I have said has not been said before.

But the very common occurrence of this form of inflammation of the lung renders it all the more important. The varying character of the lesions has confused their essential and their accidental characters, and I think it is worthy of consideration whether the views which I have advanced concerning the pathology of the disease are not the true ones, namely, that the inflammation is essentially and from the outset an interstitial one, more or less complicated by other conditions.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M. D.

ENKATARRHAPHIA OF EPITHELIUM.

The artificial production of tumors in animals has often been attempted in the hope of discovering the laws governing their development in man. Thus far but little success has been obtained, especially in the production of a new and atypical growth of epithelium. The experiment has usually been based upon the transplantation of a portion of tissue directly from one spot to another. Kaufmann[1] has varied this by leaving the skin in connection with its own subcutaneous tissue, but at the same time surrounding it by connective tissue. This is easily accomplished as follows: A small oval cut (five to ten mm. long by two to four mm. wide) is made through the epidermis, and the adjacent edges loosened. These are then raised over the included bit and united by fine sutures. In very thick skin they must be undermined for a short distance, in order that they may be joined over the sunken portion without tearing. If the wound heals by first intention there is an epithelial layer nourished from its own base and touched on all sides by fibrous tissue.

In hairy animals this succeeded with difficulty, as although the wounds readily closed they rarely remained so for any length of time. It was then suggested to operate upon the combs and wattles of fowls, which are absolutely hairless and without glands of any sort. Several places could be used at the same time upon the same bird, and could be cut out for examination whenever wanted. In this way the process was followed to the two hundred and tenth day.

In the successful cases the result was constant. The epithelium never disappeared, but continued to grow.

In the earliest days it remained flat, and covered the underlying tissue, which was rich in engorged blood-vessels, and only sparsely infiltrated with cells. No strain was exerted upon the inclosed piece, as there was no tendency of the edge to bend up. In a few days more, however, the epithelial line began to assume a bowed shape, due to an increased width, as shown by careful measurements. It continued to grow in this direction until the upturned edges met, and there was thus formed a little cavity lined with epithelial cells. A peculiar fact was noticed, namely, that this new-formed layer exceeded the old in thickness, and that desquamation was more abundant from the upper (new) layer than from the lower (original) layer. In no case was there ever the faintest trace of growth downward into the corium, either in the form of tongue-shaped projections or nests of isolated cells. With this formation of a wen the end was reached. At the close of the seventh month the cavity was no larger than in the third week.

In the surrounding tissue the cellular infiltration and hyperæmia gradually subsided. The connective tissue became firmer, its fibres and vessels took the regular direction of the fixed corium, from which, finally, it could not be distinguished. If this was all that happened the matter should be left here, but there was an unexpected occurrence which is of importance, and not so easily explained.

In preparations made from specimens of the second or third week there were found groups of large cells scattered throughout the cicatricial tissue or in the immediate vicinity. These were composed of a delicate protoplasm, without marked differentiation of their contour, with large numbers of nuclei, which were in part regularly and in part irregularly arranged. In the elongated cells they lay parallel with the long axis, while in the rounder cells they were parallel among themselves. Such must evidently be giant cells. Here and there they were packed in alveoli, and closely resembled epithelium. Careful histological examination failed to reveal any normal glandular elements that could give rise to them. At first, therefore, the idea was entertained that they arose from epidermis cells which had been loosened and scattered by the operation, and having found a suitable place in the tissue had grown into giant cells. Still they were always found at some distance from the inclosed skin, and separated from it by connective tissue. Moreover, no intermediate stages were ever seen. Giant cells have been found in the vicinity of freshly-healed wounds, and it might be supposed that these were the results of the irritation of the operation. Their life history at once removed them from this class, as they persistently increased in size and number, while those which occur in the process of cicatrization disappeared with its completion.

In the case under observation tumors as large as a bean were formed, and this size was attained about the one hundred and thirtieth day. After that they ceased to grow, but there was no indication of retrograde metamorphosis. From the presence of a little cleft in the middle of one of these clumps, and from the arrangement and shape of the surrounding nuclei, it was probable that they were formed in preëxisting spaces, which were most likely to be lymph vessels, these having been obliterated by an organization of a thrombus.

The results of the experiments are formulated as follows: —

An atheromatous cyst was formed by the development of the skin which had been buried, — a true epi-

[1] Virchow's Archiv, vol. xcvii, p. 236.

thelial formation, but not to be considered as a proper tumor, and which attained no excessive size.

In the neighborhood of this were giant cell tumors, which presented for many weeks a progressive growth, and even at the end of months showed no signs of degeneration.

HÆMAGLOBINÆMIA.

Under the above title Ponfick[1] has published an article in which he strongly advocates the theory that in hæmoglobinuria the destruction of the red corpuscles within the circulation is the essential part of the process, whether the "cathæmolytic" agent is of a chemical or thermal nature. Therefore hæmoglobinæmia must be considered as a central point, in order rightly to understand the purely secondary symptoms, any one of which by itself is no absolutely essential and regular part of the process. Even the most striking, the presence of hæmoglobine in the urine, can be entirely absent, although the destruction of a large number of colored disks has taken place.

This is with difficulty studied in those cases where the condition has been brought about by the introduction of a poison into the system. As, for example, pyrogallic acid, chlorate of potash, arsenuretted hydrogen, etc. Or where a strong thermal irritation has brought about an intense general reaction of the whole organism.

On the other hand, the influence of hæmoglobinæmia, freed from all complications, can be studied by the injection of dissolved blood into the veins of an animal. This can be obtained by freezing. Or a watery solution of pure hæmoglobine can be used. By such an experiment the author was enabled to follow the fate of the destroyed cells through all their changes. From this it appeared that the remains of the colored elements were taken up by the spleen. And this was so quickly done that a marked swelling of the organ took place — a "spodogenous" splenic tumor (from σποδός, the sediment). It was not permanent, and disappeared in the course of a few weeks.

It was much more difficult to follow the blood coloring matter that was at once freely mixed with the plasma. This does not, as is generally supposed, seek the kidney, but is taken up by the liver, which consequently secretes bile extremely rich in coloring matters. All the hæmoglobine that does not exceed a sixth of the entire amount in the body can be eliminated in this way. But from the moment when this limit is exceeded the kidneys begin to come into play, and hæmoglobinuria is associated to the hypercholia.

These latter organs are extremely sensitive to its passage. If the accumulation in the blood is only slightly increased it is precipitated in the renal tubules in the form of granular masses, which may cause their closure, and thereby lead to a cessation of the entire secretory process. In this lies the chief danger.

The author distinguishes three degrees of hæmaglobinæmia: —

(1.) The spleen and liver dispose of the constituents of the red blood corpuscles, while the kidney takes no part in the work.

(2.) The kidneys also act in eliminating the hæmoglobine, and can complete the work.

(3.) The quantity is so great that it cannot be gotten rid of, even in this way, and death follows from uræmia and hæmoglobinæmia.

[1] Berlin. klin. Wochen., 1883, No. 26.

In regard to icterus, in such cases it is hæmatogenous in nature, and arises from the progressive metamorphosis of hæmoglobine into bilirubin within the circulation. This, of course, can only take place when so much coloring matter has been set free that it cannot be taken out of the circulation by any of the three ways of egress. This can only complicate cases of the second and third groups.

In connection with this work of Ponfick, the changes in the liver and kidneys after poisoning by glycerine, pyrogallic acid, and toluyltediamine were studied by Afanassiew.[2] The doses were regulated so as not to kill the different animals by a fatal hæmoglobinuria. From the experiments the following results were obtained, which show more clearly the relation between the icterus and the presence of blood-coloring matter in the urine: —

(1.) Glycerine acts chiefly by withdrawing the hæmoglobine from the corpuscles and distributing it through the plasma. In the blood no fragments of the cells were detected. The kidneys are the active organs in elimination, and icterus does not occur. This is parallel to the cases of paroxysmal hæmoglobinuria in man.

(2.) Toluylendiamine, on the other hand, causes minute fragments to be separated from the colored elements. These, as well as the distorted and decolorized corpuscles, are taken up by the spleen, liver, bone, marrow, and also by the kidneys, but to a less degree. There is no dissolved hæmoglobine in the serum, and consequently none appears in the urine, but jaundice, of the hæmohepatogenous kind, is a marked symptom.

(3.) Pyrogallic acid occupies a middle place in its action, causing both a disintegration of the cells and a solution of the coloring matter.

The changes in the liver and kidneys vary with the agent and the length of time that it is employed.

(1.) After the use of glycerine there was found a glomerulo-nephritis, with fatty degeneration and coagulation necrosis of the convoluted tubes. By frequent repetitions there occurred an infiltration of round cellular elements, especially about the point of entrance of the vessels into the capsule, and hæmorrhage into the tubules.

There was a moderate fatty degeneration of the cells of the liver.

(2.) After poisoning with pyrogallic acid the same effects were found in the kidneys. In the liver there was a fatty degeneration, with coagulation necrosis, and a slight cellular infiltration about the central vein and in the interlobular spaces.

(3.) When toluylendiamine was employed the liver suffered most, although the kidneys participated to such a degree that a contraction of the glomeruli took place.

That these changes were not brought about by the passage of the poisonous substances through the liver and kidneys, but entirely by the free hæmoglobine and bits of the destroyed disks, was proved by the infusion of defibrinated blood warmed to 53° or 57° C.

The author describes the affection of the kidney as glomerulo-nephritis hæmoglobinurica, and in its later stages as nephritis interstitialis hæmoglobinurica, while that of the liver as hepatitis interstitialis ex ictero-hæmo-hepatogeno.

Among horses hæmoglobinæmia has been observed to occur spontaneously, and Frohner[3] has made it the

[2] Fortschritte der Medecine, 1884, p. 284.

subject of an inaugural dissertation. In this animal the noxious material is not only taken up by the liver, spleen, and kidneys, but also in extreme cases by the marrow of the bones. At the autopsy the blood and muscles presented characteristic appearances. The first contained free coloring matter, as well as urea and extractive materials. The latter were of a clear, pale-red color, and swollen from infiltration and œdema. Under the microscope there was seen in places a granular degeneration, in others a breaking up into hyaline scales, with loss of striations. From the absence of fever and of characteristic post-mortem appearances the author denies the infectious nature of the disease, which has been maintained by others, and attributes it entirely to catching cold.

THE WHITE INFARCTION OF THE PLACENTA.

This affection, to which Ackerman[1] calls attention, is of frequent occurrence, but he thinks that its true pathology has never been rightly understood.

The spots are sharply defined, but there is great variation in the form, size, color, and consistency of the portion involved. The usual shape is that of a wedge, and it is this, combined with the constant presence of fibrine, that has given rise to the term of "fibrine wedge." Often, however, it is more round or polyhedral, with a sinuous border. This last is often thrown out into true arms or projections, communicating with each other, at times so extensively as to completely mask their starting point. The color is generally a dirty white, at times a light yellow, in its earlier stages a red. In the central portion there are present illy-defined, pale yellow lines, or small rounded or elongated, glancing white elevations, usually marked by greater firmness. The volume varies as greatly as the form. The smallest scarcely reaching the size of a bean, the largest that of a walnut, or if extended more horizontally a dollar. In the last case they have their seat in the uterine surface of the placenta. In the more nodular form they generally go from one surface to the other, above which they may project, owing to their greater consistency. When very small they may lie buried completely in the placental tissue. When near the edge of the placenta they are more apt to assume the shape of a ring or narrow stripe.

From the constant presence of fibrine the older authors had looked upon them as the product of inflammation. Later the idea prevailed that they were due to hæmorrhage with organization of the fibrine, and finally some peculiar exudation was made to do duty as the cause. Ch. Robin was the only author who referred this, with other allied forms, to a fibrous degeneration of the placental tufts. This rendered the vessels impervious to the passage of blood, and was regarded as identical with the normal atrophy of the fringes of the chorion, which do not participate in the development of the placenta. Maier,[2] who has also carefully studied these changes, referred the entire process to the decidua serotina. He regarded the nodules as due to the effect produced by the growth of the projections which the serotina sends off between the cotyledons and separate villi, and which destroy the latter by the pressure exercised upon them. All the other authors regarded the connective tissue as resulting from the formation of the fibrine, while he refers it to grow from the granulation tissue accompanying these projections. Langhans referred the origin of the fibrine to the extremely thin layer which is normally present on the placental side of the chorion, even in maturity. It usually does not exceed a few hundredths of a millimetre, but in restricted places attains the thickness of a centimetre. He has called attention to the existence of numerous channels, and therefore regards it as of a peculiar nature, and calls it canalized fibrine.

These nodules are in many cases separated from this normal layer on the side of the chorion by normal placental tissue, and it is difficult to conceive how they can be derived from it. Minute examination shows that they are composed of three parts, namely, fibrine, placental tufts, and connective tissue. The first occurs either in continuous masses or surrounds the villi in broader or narrower bands, causing them to look as if imbedded in it. In either case the fibrine presents itself in two forms, either as a coarse or fine meshed network, or as a more compact homogeneous substance traversed by canals. The former differs in no material respect from the net-like arrangement of an ordinary fibrinous exudation. The formation of canalized fibrine has been the subject of much discussion.

In its general character it corresponds to the hyaline variety, about which so much has been said of late. It swells up in acetic acid. Is colored easily and intensely by ammoniacal carmine and eosine. Hæmatoxylon tinges it but slightly, and gentian violet not at all. Picro-carmine is especially adapted for its investigation as the hylanic fibrine, as well as the villi that show the same degeneration, assumes a yellowish-red color, while the true connective tissue remains clear and the nuclei of active cells are stained of a deep red.

Large cellular elements are met with entangled in the meshes. These are of a round or elongated form with a single nucleus in the centre. The circular ones have a diameter of from twenty to forty μ; the oval ones can reach eighty μ. They lie irregularly scattered or are accumulated into masses recalling the arrangement of epithelium. They correspond to the cells often described as being found in the pars caduca placentæ maternæ and its prolongations between the villi and cotyledons. In spite of their inclusion within the fibrinous mass they do not seem to have undergone its degeneration, as they present a clear, sharply-bounded protoplasm and an easily colored nucleus. On the other hand, they are at times entirely destroyed by fatty change. Finally it is to be noted that lime salts are frequently found in the coagulated material. These have an irregular, polyhedral form with jagged projections, often united with each other.

Besides the fibrine the villi form a considerable part of the infarction. They are immovable, and, as a rule, their vessels are impervious. The nuclei disappear after they have first become disintegrated and granular. Lastly the whole tuft is transformed into a translucent, homogeneous mass, which at times is permeated with fine granules or by delicate fibres running irregularly. Similar changes have also taken place in the epithelial covering. These cells lose their nuclei and are transformed into a glancing, homogeneous, or finely granular protoplasm.

The third constituent is found chiefly as new-formed connective tissue in the neighborhood of the large placental vessels. This is often extremely voluminous, appearing as broad rings on cross section, inclosing either the artery alone or it together with its vein, and is to be regarded as a periarteritis. At times this also

[1] Virchow's Archiv, Bd. xcvi., s. 439.
[2] Virchow's Archiv, Bd. xlv., s. 305.

undergoes the general hyaline degeneration. When such vessels lie within the infarction they are also found to be occluded. The method of closure varies. In places an intravascular coagulation of fibrine causes it; in others it is brought about by a proliferation of the intima.

The author regards the changes as above described as belonging to the category of those produced by coagulation necrosis. As the primary cause is to be considered the periarteritis fibrosa multiplex, the frequent occurrence of which in the placenta has still to be explained. The partial and finally entire stoppage of the arteries leads directly to anæmia, disappearance of the nuclei, coagulation necrosis of the cells, and finally hyaline degeneration of the villi and epithelium covering them.

He considers it more difficult to bring the fibrinous coagulation between the villi under this head. An exudation would be the most natural assumption, especially when it is remembered that in the white infarction of the kidney there is a thread-like coagulation which, according to Litten, owes its origin to a croupous exudation into the tubules. At the same time it is hard to conceive how this could have taken place through the obliterated vessels in the present case. It would be much easier to refer it to the necrosed epithelium and coagulation of the plasma of the blood circulating in the intervillous spaces. Then the process would be analogous to coagulation as it occurs in the blood-vessels and heart after necrosis of the endothelium, a ferment being produced by the destruction of the epithelial cells of the tufts, which could cause the fibrinogenous material present in the blood to coagulate. And in this way the entire process can be regarded, just as in the kidney, as the result of an ischæmic necrosis.

Hospital Practice and Clinical Memoranda.

CARNEY HOSPITAL.

CASE OF DIAPHRAGMATIC HERNIA. IN SERVICE OF M. F. GAVIN, M. D.

REPORTED BY W. J. GLEESON, M. D.,
House Surgeon.

JOHN E. P., a laborer, aged thirty-four, was pushed from a horse-car while it was in motion, Tuesday evening, October 14th, and in falling caught and clung to the dasher, and was dragged along by the car. He was perfectly conscious all the time, but after the accident was unable to walk or stand, and was carried home.

He entered the hospital Thursday, the 16th, complaining of sharp pain in left side, slight pain in lumbar region, and general exhaustion. Respiration was 40 per minute. On the left side there was dullness up to angle of scapula, and crepitus could be felt in axillary line from fourth to ninth ribs. There were ecchymoses over the sternum, lumbar region, and both eyes. There was no paralysis or trouble with the bladder, but he complained of obstinate constipation existing since the accident, and not relieved by laxatives or enemata. No headache or vomiting. After the ribs had been strapped he went to sleep, feeling in excellent condition. About five P. M. on Friday he complained of severe colicky pains in abdomen, which persisted for some hours. About three A. M. Saturday he showed a desire to go to stool, but could not pass anything in the bed-pan. The nurse attempted to place him in a sitting posture, thinking this might facilitate matters, when he gasped and died.

Autopsy, fourteen hours after death, by the Medical Examiner, Dr. F. W. Draper, assisted by Drs. Hooker and Gleeson, the house officers.

The diaphragm was attached at fifth interspace on left side, and on the right it bulged so as to come down to costal border. In the left mammary line, and two inches behind edges of ribs, was an opening in anterior leaf of the muscle, large as a half dollar, into and through which passed a fold of large intestine. The edges of the rent were rounded, smooth, and easily stretched. The sternum was fractured at junction of manubrium and body. The heart was nearly vertical in position, and the apex an inch to right of median line. The lower three fourths of the left pleural cavity was entirely occupied by folds of intestine, comprising all the jejunum, part of the omentum, a loop of the colon and splenic curve, in all about nineteen feet. This immense mass was distended with gas. In this cavity were also thirty-six ounces of brownish-red serum, while the lung was compressed to the upper and posterior part of the chest and reduced to one fourth its normal volume. In the axillary line on this side the fourth to ninth ribs inclusive were fractured, the ends of the fragments protruding through the parietal pleura. The right cavity contained six ounces bloody serum, and the lung was engorged posteriorly. On this side also the fourth to ninth ribs were broken, but only at the junction of the cartilages, and not completely through. The heart was contracted on the left side, but not on the right, and in the right ventricle was a partly decolorized clot, quite dry. Heart otherwise normal.

From the point of constriction the intestines were injected throughout, and commencing peritonitis was seen in places. The stomach was normal, with the exception of a hæmorrhagic spot at the fundus. The kidneys were surrounded by extravasated blood, but otherwise normal. The subperitoneal tissue in the right iliac region was well filled with blood also. There was preternatural mobility at the first lumbar vertebra, and it was found that a piece of the size of the thumb-nail was chipped off from the right inferior border, though the spinal canal was apparently intact.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

AT a stated meeting of the Academy, held Thursday evening, November 6th, DR. R. W. AMIDON read a paper on

THE PATHOLOGICAL ANATOMY OF SENSORY APHASIA,

in which he gave the details of eight cases in which he was able to present plates showing the location of the cerebral lesion. The first of these occurred under his own observation in a woman at the time of the menopause. There was incoherence of speech only when the patient answered questions. As a rule, she understood nothing that was said to her, unless it was accompanied with gestures; but gestures she comprehended perfectly. Death occurred fifteen months after

the first attack. The brain, together with a photograph representing the location and appearance of the lesion, was exhibited. The other seven cases, reported by different writers, as well as sixteen additional ones to which he merely referred in passing, as they were accompanied by no plates, he had collected from various sources in order to make the bibliography of the subject as complete as possible.

Next was read a paper by Dr. Frank H. Hamilton, entitled

THE ASIATIC CHOLERA AT SUSPENSION BRIDGE IN 1854 AND ITS LESSONS — WHAT WE KNOW ABOUT CHOLERA.

The epidemic of cholera at Suspension Bridge, two miles from Niagara Falls, occurred in the month of July, 1854, and was of a very fatal character. It commenced among some emigrants who were temporarily detained in the vicinity, and by whom the cholera infection was undoubtedly introduced into the place; and from them extended to the laborers who were engaged in the construction of the suspension bridge across the Niagara River. Many cases ended fatally within six hours, and the panic was indescribable. Dr. Hamilton thought that the violent character of the outbreak was due to the elevated temperature and moist condition of the atmosphere prevailing at the time, to the low position of the dwellings of the victims and alluvial nature of the soil, and to the fact that the ground had recently been upturned. Although carried to several of the neighboring towns, the disease did not spread in any of them, as the same favorable conditions for its development were not present in them.

Passing on to speak of the present state of our knowledge of the disease in general, Dr. Hamilton remarked that, however probable it was that such was the case, we had as yet no positive knowledge that there was a specific cholera germ. He then gave a review of the researches of Koch and other observers up to the latest dates, and went on to say that even if it should be established that the comma bacillus or other microbe was always present in cholera, and never found except in cases of this disease, we could not say whether it was really the causative agent or simply one of the results of it. It seemed quite as likely, he thought, that the infection was conveyed by the fluid in which the microbes were found as by these organisms themselves. While he was very far from wishing to underrate the value of microscopic studies he thought it was certainly a fact that not a single advance in the treatment or prevention of cholera could be attributed to the result of such investigations. For all our practical knowledge of the disease we were indebted to experience.

Having spoken of the modes in which the infection of cholera might be carried to different places, he said that the hypothesis of Koch that it entered the human system solely through the alimentary tract was by no means proven, and that there was considerable evidence to show that it also entered by means of the respiratory organs and was diffused through the circulatory system. He next spoke of the conditions favorable to the development of the disease after the infection had been introduced into a locality, many of which were present at Suspension Bridge at the time of the outbreak there. Unless the germ found a suitable soil in which to grow, cholera could not become epidemic; so that when cases of the disease were brought to places where the conditions were unfavorable to it, they were simply like the brands from a conflagration falling in spots where there was no inflammable material to be ignited by them, and therefore harmless. In this connection Dr. Hamilton related a number of instances to show how favorable low and alluvial soils, and especially freshly upturned earth, were to the development of cholera.

As to the treatment of cholera no specific had as yet been discovered, and, considering the long time that had now elapsed since the disease had been known, it was scarcely probable that one ever would be. Experience, however, had taught us how to deal with it more successfully than with any other similar epidemic. The disease could always be aborted if taken in hand in time; and the great means at our disposal for arresting it were opium and absolute rest. Opium was better than morphia, as it was less liable to disagree with the stomach, and it was better, as a rule, to give it in a solid than in a liquid form. From half a grain to one grain of the drug might be given every three or four hours until the diarrhœa was checked or narcosis was induced. There was, however, no necessity for producing profound narcosis, and this was certainly to be avoided. In case the intestinal canal contained irritating matter, it would be advisable to precede the administration with a brisk purgative. If the parasitic theory of cholera were correct, he thought that the usefulness of opium in the disease might be explained on the hypothesis that it kept the secretions in a normal condition until the activity of the microbes had ceased; most observers agreeing that their period of activity was very brief.

Having recapitulated some of the lessons to be derived from the Suspension Bridge epidemic, he remarked that if cholera should reappear in the city of New York he did not believe that it would spread as it had recently done at Toulon, Marseilles, and Naples, because here the climate was more favorable, the sewerage was better, there was not so much low ground, the sanitary regulations were better, and there was not such a large proportion of the filthiest and lowest class of the population. In conclusion he spoke of the prompt and efficient action of the New York Board of Health in stamping out cholera in former years, and referred to the successful arrest of the disease under his own direction at the work-house on Blackwell's Island in the summer of 1866.

Dr. Leroy M. Yale, who was a house surgeon on the island at the time, and who made a full report of the outbreak to the Commissioners of Charities and Correction, at the request of the Chair, gave some account of the way in which the disease spread and the means that were employed for its suppression at the work-house. The epidemic commenced on the 1st of August, and during the summer up to that time there had been an unusually large number of cases of diarrhœa, as well as of severe cholera morbus, among the inmates of this and other institutions on the island. On August 1st there were sixteen cases, and August 2d thirty-two cases, with twenty-three deaths. On this day the mortality amounted to five and a half per cent. of the total population, and on the day following to five and six tenths per cent.; but within four days it was reduced to less than one per cent. Not a single patient died in whose case treatment was commenced while the initial diarrhœa continued, and Dr. Yale thought that this outbreak taught very strikingly the fact that if,

with the enforcement of strict sanitary precautions, cases could be treated in the early stage of diarrhœa, every epidemic of cholera could be speedily suppressed.

DR. DELAFIELD thought that all would be willing to grant that cholera was an infectious disease. In regard to its having a specific germ, the latest theory of the latter was in accordance with the prevalent opinions of the times. To refer the origin of infectious diseases to certain minute organisms was the present fashion, and such fashions, whether good or bad, it generally took a long time to obliterate. The development of cholera, in accordance with this prevalent fashion, was thus referred to a particular microbe, and though Dr. Hamilton had, in his paper, stated very fairly the evidence for and against this hypothesis, he had omitted to state that out of a considerable number of investigators the testimony of an exceedingly small proportion of them could be accepted as thoroughly reliable. The technique of such microscopic researches was of so elaborate and difficult a character that the number of competent witnesses must necessarily be very small. The conditions to which Dr. Hamilton had referred as favorable for the development of cholera might be stated, he thought, to be those which were peculiarly favorable to diarrhœal disease in general. Whatever conditions would aid in the causation of diarrhœa would, therefore, render an epidemic of cholera likely to occur in case the special poison of that disease should be introduced into any locality where they existed; and, on the contrary, if this germ were introduced into a place where such conditions did not prevail there would be little danger of cholera spreading there. This evident fact seemed to indicate very clearly the rational means for the prevention of cholera, for while the importation of the disease could hardly be avoided without enforcing a quarantine so strict as to be entirely prohibitory of all commerce, the spread of cholera could certainly be successfully interfered with by the removal, as completely as possible, of all causes predisposing to diarrhœa.

DR. LOOMIS made some remarks in which he said that the first thing to determine was in which of the three classes of infectious diseases Asiatic cholera was to be ranked: those in which the causative agent was developed within the body, rendering the disease directly transmissible from the infected to the non-infected, as was the case with typhus fever and the exanthemata; those in which the morbific agent was developed outside of the body in decomposing organic matter, and was introduced into the system through the agency of water, the atmosphere, etc.; or those in which the specific poison was developed within a living organism, but was in a passive state at the time of leaving it. It was in this third class, in which it was necessary that the agent should undergo certain changes in connection with decomposing organic matter after it had left the body before it was capable of giving rise to infection, that cholera, he thought, ought to be placed. In this respect it was analogous to typhoid fever and yellow fever. Having referred to the fact that cholera was indigenous only in Bengal, and was never of spontaneous origin in any other part of the world, he proceeded to examine some of the characteristics of its spread into different localities and nations. That there was a specific cholera germ he had no doubt, and he also believed that in a large proportion of cases this entered the system through the alimentary canal. He thought, however, that it had by no means been proved that this was the sole way in which this occurred. In all epidemics of the disease there were certain nervous phenomena which indicated that the germs sometimes got into the blood also, and he thought that all we could say at the present time was that the cholera poison undoubtedly entered the body through the mucous membrane. While this, no doubt, generally took place by way of the alimentary tract, it seemed true that it also sometimes occurred through the respiratory organs, whence it obtained access to the blood. Human excrement had long been recognized as the most fruitful source of cholera infection, and most authorities agreed that the agency by means of which the infection was spread was usually drinking water or other kind of water. Through drains and sewerage was a very common way, and he thought that the reason that Rome had recently escaped a visitation of cholera, while Naples suffered so severely from the disease, was because in the former city an improved system of both drainage and sewerage had just been completed. From facts recorded at the Bengal cholera hospitals there could be little doubt that the germs sometimes entered the system by means of the rectum and large intestine, the infection being received while the patient was at the privy. While foul water was rightly regarded as almost always a source of great danger, he had seen it stated that the foulest water in India was at a post where the health of the garrison was so good that the government refused to allow any changes to be made with a view to improving it. Though the water was bad in other respects it was evident that cholera germs had not been introduced into it.

He then went on to say that all previous researches in regard to the nature of the specific germ of cholera had been insignificant in comparison with those of Koch, but in order that he himself should be willing to positively accept Koch's conclusions it would be necessary to have established beyond question that the microbe described by him was always present in cases of cholera, that it was never found in any other disease than cholera, that it was never found in the healthy body, and, finally, that inoculation with it gave rise to cholera. As far as he had been able to ascertain these points had not as yet been completely demonstrated by Koch or other investigators of his school. That cholera was a thoroughly preventable disease he thought the history of past epidemics of it unquestionably established.

DR. JOHN C. PETERS thought that the efficiency of a strict quarantine in preventing the introduction of cholera was well shown in the case of Denmark, which, while often exposed to the risk of receiving the disease from neighboring nations, always escaped until she removed the strict quarantine which she had always maintained before, when an epidemic occurred in the country, in which there were seven thousand cases with four thousand deaths. The quarantine was then reëstablished, and there had been no more cholera there up to the present time. The same thing was shown in the case of Greece, into which cholera was introduced by the French soldiers during the Crimean war, but which had always subsequently been free from the disease.

— Dr. Neumann, Professor of Psychiatry at Breslau, died October 10th, aged seventy-one.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, M. D., SECRETARY.

THURSDAY evening, September 11, 1884. The President, DR. JAMES TYSON, in the chair.

DR. J. M. BARTON presented a specimen of

CYSTIC-PAPILLARY ADENOMA OF THE NECK,

which he had removed from a patient at his clinic at Jefferson Medical College on September 6th. The patient was a married woman, thirty-one years of age, the mother of three children. The tumor was of slow growth, having existed for five years, and having increased but little in the last two years. It gave no pain and but little deformity. It was about the size of a walnut, and lay beneath the clavicular extremity of the left sterno-cleido-mastoid muscle, in close proximity to both the subclavian and carotid arteries, from which it received a decided pulsation. On strongly pressing the tumor upward and outward the pulsation ceased. The tumor was closely adherent to a number of large veins of new formation, which greatly increased the difficulties of its removal.

On section it presents a number of alveoli of variable diameter, communicating with each other, and lined with a thick membrane similar in appearance to the inner coats of the arteries. This membrane seems to have undergone calcareous degeneration in some portions. When the tumor was fresh these cysts, on incision, were filled with a dark-red fluid like disintegrated blood.

Report of the Committee on Morbid Growths.

"A section made from the tumor of the neck presented by Dr. J. M. Barton shows a stroma of fibrous tissue in which cavities are seen, varying in size, lined with an epithelium having a cuboidal shape. From the margins of many of these cavities papillary ingrowths were noted covered with cylindrical-shaped epithelium. Other cavities are filled with the remains of cells or a structureless colloid-like substance. The tumor may, therefore, be considered a cystic-papillary adenoma, in which a colloid degeneration has occurred, or, from its location, it is not improbable that it may be either an outgrowth from or a supernumerary thyroid gland."

SEMI-ANNUAL CONVERSATIONAL MEETING, OCTOBER 23, 1884.

THE President, E. O. SHAKESPEARE, M. D., in the chair.

DR. FRANCIS DELAFIELD, of New York, by invitation, read a paper on

THE PATHOLOGY OF BRONCHO-PNEUMONIA.[1]

DR. PEPPER said he had listened with very unusual interest to the paper of Dr. Delafield, in which he had so distinctly and concisely set forth his views on this very common disease.

He thought that all who had listened to Dr. Delafield would agree with him in congratulating the author upon the clearness and force with which he had described a condition which had hitherto often been confused by prolix description and by want of definiteness in separating different anatomical conditions. In regard to the term "broncho-pneumonia," which Dr. Delafield prefers, he has proved by his anatomical studies of the infiltration of the bronchial walls and of the surrounding parenchyma that this term is strictly applicable to the cases upon which this paper is based.

Dr. Pepper stated, however, that though chiefly from a clinical stand-point he was inclined to prefer the term catarrhal pneumonia, as probably including the form described by Dr. Delafield, as well as certain other forms which seem to him to be necessarily included in a complete picture of the disease.

For instance, there are many cases in adults which begin with rigor, followed by high fever, with temperature of 102.5° to 104° F., with cough hard and dry at first, and later with muco-purulent expectoration, with no very definite physical signs, careful examination will show local impairment of resonance, coarse crackling râles on deep inspiration, and weak vesicular murmur. This condition may be limited to the apex or to the neighborhood of the root of one lung, or may occur elsewhere. The cases have a duration of from eight to twelve days, and terminate by lysis with resolution, though not rarely some cough remains, and the lung is sensitive and prone to recurring attacks, which in subjects predisposed to phthisis may induce that disease.

It seems to me difficult to regard these cases as anything else than mild catarrhal pneumonia; for this type of pneumonia agrees with other catarrhal affections in the wide range of severity presented by different cases. On the other hand, there are cases much more common in children in which disease extends from the bronchial tubes into the lobules to which they lead.

The commonly accepted opinion that the lining of the alveoli and air vesicles are susceptible to catarrhal inflammation appears to me well established. In such cases the disease may extend outwards to the peribronchial tissue, as emphasized by Dr. Delafield, and lead to secondary interstitial changes, and also in consequence of obstruction of the bronchiatelectasis occurs; the aspiration of irritating bronchial products fills some of the alveoli, or finally they become impacted with the results of catarrhal inflammation of their walls. Subsequently caseation, with softening, may give rise to small abscesses, with breaking down of the walls of the air vesicles, or with perforation of the pleura, or inspissation may occur, with reabsorption of infectious material with the development of general tuberculosis.

It did not seem necessary to dwell upon the cases in which atelectasis occurred as a primary condition with the subsequent development of pneumonic centres.

It seems to him impossible to consider catarrhal pneumonia without taking the comprehensive view which would include all the varieties above indicated; though the term of "broncho-pneumonia," as used by Dr. Delafield, might be most appropriate to the special conditions described by him.

Allusion was made to the very interesting physical signs attending the course of atelectasis in the course of catarrhal pneumonia of children or of adults where considerable areas of the lung, or even an entire lung, might pass into this state, to be followed before long by the reëstablishment of respiration and the disappearance of the physical signs. Difficult questions of differential diagnosis may present themselves, requiring critical examination. From an allusion made by Dr. Delafield it appeared that he regarded lobar pneumonia as being

[1] See page 484 of this number of the JOURNAL.

like broncho-pneumonia, induced by the ordinary causes of idiopathic inflammation. The argument does not favor all lobar pneumonia being a specific constitutional disease, or as dependent upon a special microbe, did not appear to Dr. Pepper to be conclusive, and he was glad to know, from the remarks of Dr. Delafield, that he holds the same view.

DR. BRUEN said he rose to call attention to the observations of Hamilton, of Aberdeen, in reference to the peculiar basement membrane of the bronchial tubes, which determines the chronicity of bronchitis, and probably the interstitial changes in chronic broncho-pneumonia. Hamilton, in speaking of the denseness of this basement membrane, gives it the importance of a fascia, which determines the direction in which the inflammatory products of bronchitis shall be absorbed, namely, by the lymphatics, rather than by free exudation into the bronchial lumen. The interlobular connective tissues are permeated with fibrous bands, which radiate from the fibrous coat of the bronchi toward the pleural surface. Dr. Bruen thought that if careful study of the lymphatics were made the absorbed products of an acute or subacute inflammation could be traced throughout the lung, finally leading to enlargement of the bronchial glands.

The importance of the basement membrane is further illustrated by the phenomena of pneumonikoniosis and anthracosis. Immediate absorption from the bronchial tubes does not occur, although the tubes are always exposed to carbonaceous matter as evinced by the blackened sputa, yet the tubes are unpigmented, the carbonaceous or organic dust being carried down into the alveoli, whence it is absorbed, and the whole parenchyma of the lungs and the bronchial glands are blackened, but always strictly in the course of the lymphatics.

In children of a strumous habit forms of bronchitis of an obscure nature often occur. Congested areas near the root of the lung are recognizable — abundant mucous râles and frequently laryngeal spasm at intervals is an important symptom. These symptoms are often referable to enlargement of the bronchial glands — and the nervous symptoms are due to irritation of the pneumogastric nerves.

DR. J. C. WILSON asked whether Dr. Delafield designed to describe one variety of a group of affections to which the terms broncho-pneumonia, catarrhal pneumonia, desquamative pneumonia, etc., are somewhat vaguely and interchangeably applied, or to include the whole group in his account, and under the designation of broncho-pneumonia. If Dr. Wilson had understood the paper aright, he thought it certainly had referred to an especial variety of the affection in question, for there are encountered cases which differ both clinically and anatomically from the disease described by Dr. Delafield, and in which the lesions spread not only in a direction internal from the affected bronchial tubes to the peribronchial structures, but also in the direction of the long axis of the tubes to involve the terminal (subpleural) vesicles, and this, according to widely accepted views, often without antecedent atelectasis.

DR. CARPENTER said that he had very little, indeed, to give of value in a pathological discussion, but would say at the same time that after thirty years' experience he had arrived at certain conclusions, not perhaps new, but which had been gathered in one set of cases, namely, anthracosis. They are a very striking set of cases. They all originate in a bronchitis, which differs from the ordinary form of that disorder in one very striking symptom, namely, great oppression of breathing. This oppression is far greater than can be accounted for by ordinary bronchial inflammation. It depends on interstitial disease or peribronchitis. A true broncho-pneumonia is set up, the cause being a special one, namely, inhalation of coal dust. In these cases so great obstruction to the circulation is caused by the interstitial exudation that the circulation is very seriously embarrassed. The heart suffers — dilatation, or hypertrophy with dilatation, is produced, and a form of dyspnœa, known as miners' asthma, occurs. These cases are essentially chronic ones. He had only the day before seen a patient die with this disease who had been under his care for several years, and in whom no lesions but those of peribronchitis could be detected.

Many of these cases, however, in a chronic progress, do develop all the symptoms of phthisis. Slow alterations of structure occur, cavities form, and all the pathological conditions of the so-called fibroid phthisis are found on post-mortem examination. He, therefore, claimed that these cases are entitled to constitute a special form of broncho-pneumonia. He agreed with Dr. Pepper that acute or subacute broncho-pneumonia left sensitive areas, leading often to subsequent phthisis. In his observation, fibroid phthisis was not a true tuberculosis, but a chronic degeneration of lung tissue, due to a preëxisting broncho-pneumonia, such as he had observed in anthracosis.

DR. OSLER said that his experience in many points tallied with that of Professor Delafield. In the broncho-pneumonia of adults the pneumonic process, he believed, most usually spreads from the bronchi. He referred also to those cases of broncho-pneumonia which followed brain injury, or disease affecting the pneumogastric centres. In such cases the disease was deeply seated, and we find that the morbid process often surrounds the bronchi, but does not involve the terminal alveoli. The reverse is true in the case of children, in whom the disease is more peripheral, is nearer, and may be just beneath, the pleura. He was glad that Dr. Carpenter had raised the point as to anthracosis. Dr. Osler had been able to examine several cases of this affection in its very early stages, and could testify that it begins in the bronchi and thence extends to the peribronchial tissues. It is primarily, then, a broncho-pneumonia, and in every case he had found small disseminated black lumps resulting from localized broncho-pneumonia, which, by their fusion and extension, produce a form of fibroid phthisis.

DR. TYSON had little to add to what had already been said. He had, however, first expressed his gratification at the simple clearness with which Dr. Delafield had presented the question. Dr. Tyson had been very much impressed with the diversity of nomenclature of the disease under consideration, and it would be useful if we could agree upon some common term. For a long time desquamative pneumonia had seemed to him to be the best term, but from a study of the pathological histology he thought the term peribronchial pneumonia more suitable. If now the adjective desquamative be added we have a term which will be still more comprehensive and exact.

Dr. Tyson thought that our understanding of the enormous peribronchial cellular infiltration would be much simplified if we lose sight altogether of the idea that there is essentially any form of inflammation ex-

cept interstitial inflammation. He had come to the conclusion that there is no such thing as catarrhal or parenchymatous inflammation, the phenomena usually considered characteristic of these being secondary. The wandering out and massing of leucocytes is the one essential factor of the inflammatory process. He would like to ask Dr. Delafield where he would draw the line between this process and tubercular phthisis. He presumed that Dr. Delafield agreed with all other observers in admitting that broncho-pneumonia does sometimes terminate in tubercular phthisis, and when this occurs it is often difficult to say where the broncho-pneumonia ends and where the phthisis begins, although the extremes may be easy of recognition.

Dr. Formad would like to ask the lecturer's instruction how to distinguish broncho-pneumonia in its *chronic* form from *tubercular* broncho-pneumonia. Like Dr. Tyson he felt that he was unable to draw a line of distinction between the two affections. Indeed, Dr. Formad was unaware of a non-tubercular form of broncho-pneumonia in man until he saw Dr. Delafield's excellent records and representations of this lesion, this being explained by the fact that Dr. Formad dealt almost entirely with the dead, while most of the speakers had shown that although broncho-pneumonia in its *acute* form was a common disease it did not prove fatal in the vast majority of cases, the patients either getting well or the disease assuming a chronic course.

Dr. Formad fully recognized *acute* broncho-pneumonia as an independent affection, although he believed he had observed this lesion *post mortem* only in dogs, such as induced artificially by means of forced inhalations of a spray containing irritating particles. Dogs with such artificial broncho-pneumonia (even if tuberculous sputum was resorted to to induce it) Dr. Formad had observed always to recover within a couple of months, but if the dogs were killed before the end of the first month after the operation the post mortem showed invariably an acute broncho-pneumonia not distinguishable from that described by Dr. Delafield as occurring in man. Throughout the lung substance are seen small nodes of irregular outlines, in size resembling tubercles.

Under the microscope these nodules are seen to consist of mere unorganized collections of cells, often in a state of retrograde change and mixed with mucus and débris, this exudate being limited to the lumina of the bronchials and their pertaining groups of air vesicles (the acini) which they fill. On section these artificial boundaries give rise to the appearance of nodes. Very often epithelial cells and mucus from the bronchi have been seen intermingled with the purulent contents within the air vesicles. This suggests that the exudate contained in the latter may have been partly aspired from the bronchi (during forced breathing) and was lodged in the air vesicles as foreign material.

These lesions have been mistaken by stupid observers for true tubercles. *Acute* broncho-pneumonia in man appears to be a lesion perfectly analogous to the one described above in dogs. The human disease once becoming chronic, its distinction from tuberculous broncho-pneumonia ceases.

Dr. Delafield, in closing the debate, said that all the speakers had brought out what was one of the most difficult points concerning broncho-pneumonia, namely, its limitations. Strictly speaking every pneumonia is a broncho-pneumonia, and the application of the term to a certain group of cases is, of course, arbitrary. He believed, however, that the name is most properly employed to designate the group of cases which he had described.

In anthracosis there is a chronic bronchitis and also a chronic pneumonia, but yet the lesion is not, properly speaking, a broncho-pneumonia.

He did not believe that the inflammation traveled directly from the bronchi to the air vesicles into which they entered, but that the appearances which simulated this were due to atelectasis.

He thought that the term catarrhal pneumonia was a very bad one, and that the air vesicles were structures entirely different from mucous membranes.

He did not believe that broncho-pneumonia was a form of phthisis or lead to phthisis, but that phthisis had its own special anatomy from the very beginning.

Recent Literature.

Diseases of the Throat and Nose, including the Pharynx, Larynx, Trachea, Œsophagus, Nose, and Naso-Pharynx. By Morell Mackenzie, M. D. London. Vol. II. Illustrated. Philadelphia: P. Blakiston, Son & Co. 1884. Octavo, Cloth. $3.00.

This volume completes Dr. Mackenzie's work on the Throat and Nose. The first volume, published four years ago, treated of the affections of the pharynx, larynx, and trachea, and was justly considered as nearly perfect as possible. The volume now before us, which consists of three sections, (1) Œsophagus, (2) Nose, and (3) Naso-Pharynx, is fully up to the first. The general arrangement of the two volumes is the same. Nearly every chapter is preceded by a concise, interesting, and oftentimes instructive historical sketch of the disease to be described, which gives the author ample opportunity to acquaint us with many literary and pathological curiosities which his extensive research has brought to light, and for which he has an evident relish. At the end of the chapters illustrative clinical cases are added, taken, in most instances, from the author's own unrivaled experience. Foot-note references to the writings of others are frequent throughout the book. Dr. Mackenzie appears to us to have been especially liberal towards his American confrères — perhaps in some cases too much so — in mentioning their instruments, methods, and writings. We fail to understand, for example, what benefit his readers can derive from perusing the long foot-note on page 313, copied from a work on Catarrh by an American author. This writer details a number of complications of nasal catarrh which could never have had any existence except in his own imagination. These Dr. Mackenzie reproduces at length, and then adds ironically that such symptoms are fortunately not met with in Great Britain. Neither are they met with in the United States, as Dr. Mackenzie well knows, and we regret that such statements having an American origin should be found in a work which is to enjoy such a wide circulation as the one before us.

The illustrations of morbid appearances are mostly originals; they are well executed, and very instructive. Too much space, however, is given to the drawings of the various insufflators, nasal douches, nasal spray producers, and pneumatic spray producers. These have long been familiar to all; they are constantly being modified and improved, and some of those pictured in

this volume are even now antiquated, at least in this country. The chapter on Nasal Instruments, in fact, resembles a chapter from an instrument maker's catalogue, for it contains the good and the bad. The volume closes with an appendix containing special formulæ for topical remedies, and an excellent index of subjects and authors. The first two hundred and thirty-four pages of this volume are devoted to the gullet: its anatomy, how to examine it, its diseases, and a description of œsophageal instruments. The author gives the results of his experiments to determine the calibre of the gullet, which show that its transverse diameter is very considerably greater than the antero-posterior measurement. In sounding the gullet, therefore, he recommends bougies somewhat flattened antero-posteriorly, as they adapt themselves more easily to the lumen of the tube through which they are meant to pass. In the chapter on Œsophagitis in Infants it is stated that the reason why English writers subsequent to Ryan (1835) have altogether passed over the disease is because that even in children's hospitals patients under two years of age are not admitted. In this connection we find a word of praise for Dr. Haven's hospital in this city, which is exclusively devoted to infants under this age.

Dilatations, malignant tumors, and cicatricial stricture of the gullet are treated in a thorough and brilliant manner. The various operative methods for stricture are fully considered. As regards internal œsophagotomy, the author thinks increased experience will show that though its immediate results are not so frequently fatal, its ultimate effects, even when successful, are less beneficial to the patient than either gastrostomy or œsophagostomy. Dr. Mackenzie gives the preference to gastrostomy, as it is both safer and easier to perform, and *always* meets the difficulty to be overcome, namely, the obstruction to the passage of food into the stomach, except in those comparatively rare cases in which the stomach itself is also diseased. Judging from statistics alone, he says, operative interference would seem to be attended with less satisfactory results than the milder palliative measures generally adopted. The average duration of life in his own series of one hundred cases of malignant stricture of the gullet in which no operation was attempted was *eight* months, while the average extent of life after the first manifestation of distinct symptoms till death in fifty-three cases in which gastrostomy was performed was *seven* months. Recent records, however, show much better results, and the author claims that as the increasing resources of science render earlier recognition of œsophageal disease possible the results of the operation will be still more satisfactory in the future.

From a literary point of view the chapter on Rupture of the Gullet is one of the best in the book, and is a model of the complete and painstaking manner with which Dr. Mackenzie works up a subject.

Succeeding chapters are devoted to Wounds, Foreign Bodies, Neuroses, Spasm, and Malformations of the Gullet. This section on the œsophagus is the most important part of the book, although in the remaining half of the volume the diseases of the nose and nasopharynx are discussed with great ability, and the extraordinary amount of labor which has been expended on the work is evident on almost every page.

In the chapter on Hypertrophy of the Nasal Mucous Membrane treatment with the electric cautery is recommended as the most simple and efficacious method. Not a word of caution, however, do we find in regard to applying the cautery, or any mention of the accidents which sometimes follow its use in the nose. The treatment of nasal polypi by evulsion, abscission, and electric cautery is considered in detail, and here, again, the preference is given to the cautery. Abscission with cutting forceps is held to be preferable to evulsion, and the author states that there are some polypi which, from their anatomical situation, cannot be extirpated unless a portion of the turbinated bone is also taken away.

Although the chapter on Hay Fever contains nothing new it is compiled in a manner which can only be described as Mackenzie's, and will be read with enthusiasm.

Taking this work on the Throat and Nose altogether there can be but one opinion in regard to it. It is a credit to medical literature, and will always occupy a place among the standard works. As a text-book it is exhaustive and reliable, in short, *the best*, in our judgment, which at present exists in any language.

F. H. H.

The Formation of Poisons by Micro-Organisms. A Biological Study of the Germ Theory of Disease. By G. V. BLACK, M. D., D. D. S. Philadelphia: P. Blakiston, Son & Co. 1884.

This is a series of lectures delivered at the Chicago College of Dental Surgery. From the title we had hoped to find some original investigation, but in this we were disappointed. The first part is a historical résumé of the work of Koch, Pasteur, and others. The second part is devoted to a consideration of the action of cells upon foreign substances, and the method in which they are gotten rid of. The process the author considers is due to the production of a ferment, and similar to digestion. He, however, is not able to show that the substance has been isolated in all cases. He then goes on to show that the action of micro-organisms is dependent upon a poison of a nature similar to the alkaloids. This, however, has been separated in so few cases that a generalization is hardly warranted as yet. The point made is summed up in the sentence, "The cells attacked either digest the invading germs or the invading germs digest them." We cannot quite agree with the author, and think that the word destroy for digest would be of rather wider application and nearer the mark. The last part of the book gives a description of the different forms of caries found in teeth, and the part in their production which is played by the bacteria, as shown by the works of Dr. Miller.

The Elements of Pathology. By EDWARD RINDFLEISH, M. D. Translated by N. H. MERCUR, M. D., and revised by JAMES TYSON, M. D. Philadelphia: P. Blakiston, Son & Co. 1884.

As the author says in his preface, this book is intended for those who have already a knowledge of the subject rather than as a systematic treatise for beginners. Considered in this light it certainly may fill a niche as the translator hopes. The subject has been treated from the stand-point of ætiology in the association of processes rather than from purely anatomical grounds. From the great experience of the author

there are many valuable suggestions. For example, the concise and simple way in which the changes in the heart produced by disease of its valves is stated. At times, however, he seems inclined to speculation, and to draw conclusions from evidence which is certainly weak if not wanting in some of its points, and it is especially on this account that it is hardly to be recommended to younger students. The style of the original is undoubtedly involved, and it is not the fault of the translator if some passages are a little obscure. The rather inferior quality of paper and type is, probably, necessitated by a desire to keep the price within reasonable limits.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 20, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

CHOLERA NOTES.

BOSTON BOARD OF HEALTH.

BY reason of the outbreak of the cholera in Paris the Boston Board of Health has issued more stringent orders to the Port Physician in regard to the examination of passengers and baggage which may arrive here from foreign ports, especially on the French coast. The orders sent out by the Board at the time the cholera recently appeared in Italy are still in force also, but to guard against any possibility of this disease gaining a foothold here particular care will be taken to examine persons and merchandise coming to this port from localities in France. The work of looking after places in the city, as courts, alleys, cellars, etc., especially in the tenement house districts, which have been allowed to remain in a filthy condition by the owners and inmates, is being prosecuted with vigor.

THE EMBARGO ON RAGS.

Secretary of the Treasury McCulloch issued, November 15th, the following circular to customs officers: The unloading in the United States of old rags shipped on and after the 20th inst. from foreign ports or countries now or hereafter known to be infected with contagious or epidemic diseases is hereby prohibited. France and Italy, and all Mediterranean and French ports, are declared to be infected within the meaning of this order. Old rags gathered or baled in infected ports or countries, or shipped from other ports or countries, are also prohibited from being unladen. No old rags shall be landed at any port of the United States except on a certificate of the United States Consular officer at the port of departure that such rags were not gathered or baled at, or shipped from, any infected place or any region contiguous thereto. This circular supersedes No. 145 of August 30, 1884, and No. 162 of October 23, 1884, on the same general subject as to shipments made after the date specified, and will remain in force until further notice. This order will not be construed to allow the unloading of any old rags except upon the general permit of the local quarantine or health officer.

The Marine Hospital Bureau is informed that the cost of disinfecting rags abroad by the boiling process is $3 a ton.

NEW YORK STATE BOARD OF HEALTH.

The following notice has just been issued by the State Board of Health at Albany through its secretary, Dr. Alfred L. Carroll: —

"Local health officers and Boards of Health are hereby apprised that the rapid advance of cholera in Europe threatens the invasion of this country, which may occur at any moment, and are notified that the State Board of Health expects a strict performance of the duties imposed upon them by law. Among these duties are the determination of the period of quarantine of vessels, vehicles, or persons arriving from an infected locality; the regulation of intercourse with infected places; the suppression and removal of nuisances; the examination of places where the conditions are dangerous to public health, whether known or believed to exist, and to report promptly to the State Board of Health all facts relating to epidemic disease, and require such isolation and quarantining of persons, vessels, and sources of infection as shall be necessary; — in brief, to use all possible means to avert the introduction or prevent the spread of an epidemic as disastrous as cholera has everywhere been. These duties are not discretionary with local Boards of Health. The law is mandatory, and evasion or neglect will not be tolerated in the face of danger which menaces a community. Experience has shown that cholera poison does not extend where no filth favors its multiplication, and that the only way to obstruct its march is to remove all sources of pollution of soil, air, or water. In excremental contaminations especially lies the greatest risk, and all such conditions must be at once removed."

Sanitary Superintendent Day states that New York City has never been in a better condition to resist the ravages of cholera than at present, while the officials of the Health Department are energetic, competent, and constantly on the alert.

POLITICS AND PUBLIC HEALTH.

SOME months ago the JOURNAL commented editorially upon the reflex nervous and psychical effects of those occupations in which events largely outside the control of the operators made success or failure, particularly stock-speculation and dealing in "futures" generally. A new phase of this subject is suggested by the political campaign through which we have just

passed. To her devotees Fame is perhaps even more alluring than wealth. Men seek the bubble Reputation even where they will hardly follow for lucre.

What form of excitement can cause a more tremendous strain upon the nervous energies of its victim than the life of the professional politician! The contest which begins with (or even before) the "primaries," which thickens as the time approaches for the nominating convention, with its skirmishes, its attacks, its plots and counterplots, culminating in success or failure in carrying the nomination; which without a breathing space plunges into the thick of the battle for votes; the bargains for securing influential supporters; the physical exhaustion of taking the stump, the addressing of three or four audiences each day, and the traveling at night; the widespread publication before a gaping world not only of one's public record but of the most personal and secret matters of the private life; the shafts of vituperation and falsehood which cannot but leave their mark upon the most callous heart; the still more degrading effect of setting in motion this same vile enginery against an opposing candidate; and last, but not least, the strain of alternate hope and despair after the vote is taken and while the result is yet in doubt, — all this is an experience than which nothing could put a greater strain upon the whole mental and physical being. Those who have played for the highest stake in our political life and have lost, as has been the fate of not a few of our leading statesmen, may not have always owed their death directly to the mental strain and disappointment, but evidence is not wanting in several instances of a breaking up of health and courage after the great ordeal which never was recovered from. To go no further back than the memory of the present generation, we may mention Clay, Webster, Stephen A. Douglas, and Horace Greeley as melancholy instances of this. And what else could be expected? The attainment of the prizes of speculation is often a relative thing. All is not staked on one venture, and if the success is not all that was desired it may yet be considerable. But a public man who has been smitten with the presidential fever must either win his goal or fail utterly. For years he has kept his eye on the White House, and every public act has been viewed in its possible relation to that objective point. As his plans succeed and the goal comes nearer, his efforts and his excitement increase. And finally, when the prize is almost within his grasp, what must be the tension of every mental and physical fibre as he summons them to the aid of his supreme effort.

But this subject has bearings of more practical interest to the community than those relating to the presidential contests alone. The unnecessary frequency of the elections in many parts of this country is productive of evil results not only to the small army of candidates but to the general public, who waste a large amount of time, energy, and money over every election. In this city, for instance, the smoke of the last battle has not cleared away before we are involved in a municipal contest. One day in the year, or better still, one day in two years, should suffice to devote to the exercise of the elective franchise, and there seems no good reason why all State and municipal officials should not be voted for at one balloting.

One other and still more important point in which politics may be said to touch upon public health is suggested by the nervous strain which, under our present Civil Service system, is put upon the great body of Federal office holders at each national election. Every four years their means of livelihood are threatened. In the uncertainty of their tenure of office there is at all times, indeed, a degree of anxiety, but once in four years their risk becomes so imminent that they are virtually put into the position of playing for a stake, that stake being nothing less than their bread and butter. While the gambler's play affects only himself, the politician is able to put into the wager not only his own political ambition but the hopes, the anxieties, the mental health and happiness, and even the physical subsistence of a hundred thousand of his fellow citizens.

CHOLERA AND RAGS.

THE Treasury Department at Washington has issued another order relative to the importation of old rags under date of November 15th, the substance of which will be found in another column. This order supersedes those issued August 30th and October 23d, and prohibits the unloading in the United States of old rags shipped on or after the 20th instant from foreign ports or countries now or hereafter known to be infected with contagious or epidemic diseases. The order will remain in force until further notice.

We deprecated the issue of the first order as arbitrary and exaggerated. Such steps at first give a false feeling of security, and ultimately tend to diminish the respect and confidence which may be entertained towards the departments from which they emanate. As far as any facts exist on the subject, they do not show that old rags in the bale, as used by paper-makers, are especially dangerous conveyancers of contagion, but they do show that immigrants and their effects are. If there is any necessity for, or possibility of, regulating the one, in a still greater degree should it be true of the other.

It is to be hoped that central and local authorities will coöperate harmoniously in the enforcement of such regulations as may be deemed desirable under existing conditions; but it is no less to be hoped that such regulations will only be proclaimed after due reflection and under sufficient advice. Mere energy and activity, if fitful or ill-directed, will do more material and moral harm than good.

SIR JOSEPH LISTER ON CORROSIVE SUBLIMATE.

A MOST interesting address was delivered by Sir Joseph Lister at the opening meeting of the Medical Society of London, which was reported in the *Lancet* and *British Medical Journal* of October 25th. It con-

tained an account of the author's experience in the use of corrosive sublimate as a surgical dressing, and of his experiments with a combination of sublimate and blood serum. Professor Lister did not consider the subject by any means exhausted nor its practical application fully established, but he "ventured to hope" that the interest of some of the points might justify him in bringing it to public notice.

It is a very generally received view in the profession, not to say among professed chemists, that albumen forms, with corrosive sublimate, an insoluble, or very sparingly soluble, albuminate; and that this albuminate is inert; whence the efficacy of white of egg as an antidote in corrosive sublimate poisoning. If it were really true that the albumen, acting in a certain proportion on the corrosive sublimate, would form with it an absolutely inactive compound, this would be a very serious consideration for the use of corrosive sublimate in surgical practice. The albuminous (proteid) constituents of the blood are enormously abundant; while the quantity of corrosive sublimate which can be used in surgical dressings cannot be very great. According to the most recent views regarding albumen, its chemical equivalent is about six times that of corrosive sublimate; but the quantity of albuminous material in the serum of the blood is very much more than this in proportion to any amount of sublimate that we could have in our dressings.

Experiments made directly with blood serum and corrosive sublimate showed that if serum is mixed in small proportion with corrosive sublimate in a mortar the result is the production of a thick, opaque, slimy material, but if more serum is gradually added this material is redissolved in the serum until, if as much as 150 parts of serum to one of sublimate is used, a clear solution results.

Such a combination of sublimate and albumen is very mild and unirritating in its action, and gauze made with solutions of one part of sublimate to fifty of serum proves unirritating to most skins. In very few cases the one to fifty gauze has caused some irritation, which has, however, disappeared when gauze prepared with one part of sublimate to one hundred of serum was substituted.

The serum used for such dressings is obtained from horse's blood, which separates most completely in coagulating from the blood corpuscles, and is, therefore, to be preferred to beef blood, the serum of which contains a large number of corpuscles.

How far Professor Lister's experiments may be successful in furnishing a surgical dressing for general use is certainly very uncertain.

If the serum is treated with a certain proportion of sublimate, not sufficient to make it solid, it may be kept for any length of time. Professor Lister thinks it possible that this sublimated serum may come to be an article of commerce, which may be used in hospitals or even in private practice. A material of this kind, dried and reduced to powder, may come to be used for the purpose of mixing with vaseline for an antiseptic ointment or even for dusting in, under certain circumstances, among the dressings.

The interest in the subject which the distinguished surgeon feels will, probably, be shared by his readers, but any one who follows carefully the work the address details can hardly fail to take an equal interest in the exposition of the methods of study and the careful observation which preceded and led up to the use of blood serum.

CHOLERA IN PARIS.

The situation at Paris has not materially changed since last week. The number of daily deaths has varied from eighty to twenty, and probably less than a third of the cases have proved fatal. The mortality is calculated as not exceeding one in 36,000 of the population, a ratio very commonly exceeded by that due to typhoid fever. There has been a favorable change in the weather from the warm, moist, foggy atmosphere of last week to a cooler and clearer air, and this change is accompanied by a diminution in the tendency of the disease to spread.

Such victims as the disease has made so far have been entirely from the poorer quarters of the town, from the garrison, and from one of the homes for the aged. The richer quarters have not been attacked, and it is highly probable that cholera may linger on through the winter in its present state of semi-activity until given fresh vigor by the spring months.

The mere official recognition of the presence of cholera in the city was sufficient to clear the place of strangers, unless detained by business, and to nearly empty the hotels. Many of those who have fled, we have no doubt, have exposed themselves to more real danger than if they had stayed quietly where they were and lived with circumspection. Cheap shopping and lodging will prevail in Paris this winter, and for those who do not feel nervous as to their being accompanied by illness and death it might not prove an undesirable time to go to that capital. As far as lies in the power of the government, general and municipal, sanitary precautions will, probably, be energetically practiced. On the side of the people themselves it is quite as likely that familiarity will breed contempt, and as the winter advances individual carelessness will increase rather than diminish.

Very different accounts come from different sources as to the condition of the Paris water supply. The supply is drawn from four or five different sources, which are used for different purposes and in different quarters of the city.

MEDICAL NOTES.

— Dr. Roche states (*Lancet*, April, 1884) that five drops of tincture of cantharides, three times a day, is a good remedy for children suffering from incontinence of urine. It renders the neck of the bladder sensitive, and the stimulus of the urine keeps the sphincter tonically closed till voluntarily overcome at the micturition time. In children, want of tonic contraction in the sphincter, and not excessive sensitiveness and spasmodic effort in the body of the bladder, is the most frequent cause of nocturnal enuresis.

— A rather unusual case has lately been submitted to Judge Hagner in the Circuit Court at Washington, D. C., says the *Evening Star*. This was a suit to recover from Dr. W. H. Hale one hundred dollars paid him by a colored man named Meredith under a guaranty of Hale that for that sum he would cure Meredith's son of pulmonary consumption, and in case he failed he would refund the money. The boy died, and Meredith sued Hale before a justice of the peace and obtained judgment. The case was reopened, and judgment was given against Hale a second time, and he appealed. After the testimony of the parties was given, Judge Hagner affirmed the judgment below. He declined to consider the defendant's bill in bar for attending Meredith's wife, and decided the case solely as to the original claim. Judge Hagner read the heading of Dr. Hale's circular — "Hearth and Home, sworn circulation 63,000 copies monthly" — and the signed guaranty to cure the son, and said, "This guaranty was to perform an impossibility, to reverse a decree of the Almighty, and was akin to gypsying and voudooism, which says: 'I don't want your money, but as I must touch silver I must have it before I can succeed.' The justice was right in his decision that the money should be paid back, and this court affirms that decision."

— William H. Dempsey, of Washington, D. C., is under indictment in the United States Circuit Court in this district for forgery and uttering in defrauding the United States in connection with certain clerks in the Medical Bureau Department in Washington out of some $75,000 by means of false vouchers. Dempsey is under $5000 bail.

NEW YORK.

— The graduating exercises of the Training School for Nurses of Charity Hospital, Blackwell's Island, took place at that institution on Wednesday, November 12th. The class numbered twenty-one; the largest that has yet been graduated from the School. The principal address was delivered by the Hon. Abram S. Hewitt, who in the course of his remarks expressed the belief that the development of the trained nurse and the training school was fully as great a blessing to suffering humanity as the discovery of anæsthesia. Remarks were also made by the Rev. Dr. W. M. Taylor, Dr. Fessenden N. Otis, and Dr. Seaman, chief of staff at Charity Hospital. In his address Dr. Taylor said that whatever dispute there might be about other spheres of woman's work, there was no question about her qualifications and fitness for ministering to the sick. This is the eighth class that has left the hospital with the diplomas of this School.

— The Rhinelander case was the subject of discussion at the last meeting of the Society of Medical Jurisprudence, held November 13th. The paper of the evening was read by Dr. William L. Hardy, city physician, who said that from the examination which he made of Rhinelander while in prison, and the evidence in regard to his former life, he had become convinced that he was really insane. Because the prisoner, however, had shown a retentive memory and a certain shrewdness and cunning during the investigation in regard to his sanity, many had thought that he must be sane. Some of the legal gentlemen present thought that while Rhinelander was weak in certain respects and eccentric, that did not constitute him an insane person, or release him from the responsibility for committing a crime, and that his wit and excellent memory also argued against his being insane. Dr. E. C. Spitzka said that the different experts who were called in in the case had attributed to the prisoner so many kinds of insanity that he agreed with Recorder Smith's opinion that it was impossible that he should be affected in so many ways at the same time. Mild lunatics, however, were often noted for keenness of retort and a certain amount of shrewdness and cunning; while imbeciles sometimes had unusually good memories. Judging from the symptoms enumerated in the paper he would himself have no hesitation in pronouncing Rhinelander an undoubted lunatic.

— As a means of supplementing the deficient Croton water supply, the Bronx River was tapped last summer, and for about two months now the houses above Harlem bridge, on the east side, have had water from this source alone. The water was found from the first to be offensive in taste and odor, and as this continues to be the case up to the present, the Board of Health, at the instance of a number of physicians and other residents of the district, is making an investigation in regard to the wholesomeness of this water from the Bronx.

— The corner stone of the crematory of the United States Cremation Company, limited, which is being built at Mount Olivet, near Fresh Pond station, on the Long Island Railroad, was laid November 19th, when addresses were made by Prof. Felix Adler and the Rev. Dr. Howard Henderson.

Correspondence.

LETTER FROM MR. LAWSON TAIT.

BIRMINGHAM, *November* 5th, 1884.

MR. EDITOR, — I have had very much pleasure in perusing a large number of notices, in the American medical press, of the address which I was privileged to deliver to the Canada Medical Association in August last. The compliments paid to me in these notices have been far greater than I deserved, but the pleasure derived from all of them is more than counterbalanced by the pain I have felt at an editorial comment in the *Boston Medical and Surgical Journal* (October 2, 1884). Therein you express your opinion that my address was intended more for the castigation of Sir Spencer Wells than for the purpose of laying before the profession the results of my own experience and observation.

I am truly grieved that it should be possible in any way to put such an interpretation upon anything that I have said, for certainly nothing was further from my purpose. That I detailed my differences from Sir Spencer Wells in words which were strongly expressed is true, for when I feel strongly I am in the habit of fully expressing my meaning. That I strongly condemned language which was used rashly and indis-

criminately by Sir Spencer Wells is equally true, but that I had any intention of castigating that gentleman is an impression which I desire to remove, and if any word or phrase throughout my address can be legitimately understood in that direction I hereby freely and unreservedly withdraw it, and express my regret for it.

But let it be clearly understood that mere strength of language in the expression of my opinions is neither to be retracted nor to be regretted. I do, therefore, trust that you will allow me, in order that I may not appear in an unfair position in the eyes of the numerous readers of your influential journal, briefly to narrate the relation which Sir Spencer Wells has adopted towards me during the past few years. Until the month of August, 1881, I was on terms of intimate, almost close friendship with him, and I have discussed with him in private freely and without the slightest difficulty all the points upon which we have since been publicly at variance. I could never discover that by reason of difference of opinion there was anything likely to destroy our friendship. But at a meeting of the Obstetrical Section of the International Medical Congress in London, in a public discussion of the question of the removal of diseased uterine appendages, Mr. Spencer Wells uttered this sentence: "That he had only seen one case which justified an operation, and it was a very remarkable thing that so many were reported, he supposed that they must all go to Birmingham." My reply to him was that there was probably more truth in his suggestion, that the cases went to Birmingham, than he had any idea of, and from that time, and apparently from that reply of mine, all association between us has ended. It has been repeated frequently to me that insinuations have been made in London concerning my practice of an extremely objectionable kind, and these I have traced in several instances to the lips of Mr. Spencer Wells.

During the past three years, as in many instances before that time, it has been considered advisable by patients and their friends that they should have the opinion of Sir Spencer Wells as well as mine, or that they should have my opinion in addition to his, and in all such cases I have acted upon the rule of my profession, and have communicated by letter or by telegram with him. On his part he has persistently subjected me to the most humiliating treatment which one practitioner can apply to another, that of entirely ignoring my communications, and in public he has deliberately turned his back upon me.

Under such circumstances as these it will not be a difficult matter for your readers to understand that I am not much inclined to modify language which in any case would be strong, nor to pick and choose my expressions in order to couch them with greater delicacy. I have received at the hands of Sir Spencer Wells treatment which I think any one would resent, but in spite of that I had no intention of saying one word which could be regarded as being intended for purposes of castigation. I would further point out that what I have said has been chiefly in defense of another whose positions have been assailed, whose accuracy and honesty have been called in question, — I mean Mr. Keith, — and I have said very little indeed on my own behalf. I also think I am justified in saying that what little I have said for myself was in reply to repeated attempts at castigation which have been made upon me by Sir Spencer Wells.

In conclusion I can only say concerning Sir Spencer's conduct towards myself, that it is not what we expect from an English gentleman, still less is it in harmony with the position to which, by the grace of his sovereign, he has been recently raised.

I am sir, your obedient servant,

Lawson Tait.

[We publish with much pleasure the above letter from Mr. Lawson Tait. If our editorial comment on his address at Montreal contained any element of injustice to Mr. Tait we regret it. — Editor.]

HYDROCHLORATE OF COCAINE.

Portland, Maine, *November* 15, 1884.

Mr. Editor, — Hydrochlorate of cocaine, the recently brought forward local anæsthetic, is upon trial, particularly in ophthalmic and aural practice, and therefore it should be not only a duty but a pleasure for those who are using the drug, which promises so much, to give clinical experience with the same. The writer has found that a one per cent. solution, frequently repeated, is quite efficacious, producing rapid anæsthesia of the parts, and that an operation can be performed much sooner than one would be led to suppose by a perusal of the reports of most of those who have thus far recorded their clinical experience.

Case I. G. S. D., aged seventy, senile cataract. This patient was rather timid, and preferred to take ether, but being dressed for the bed and lying in a recumbent position one drop of a one per cent. solution of the hydrochlorate of cocaine was instilled thirteen times in the course of twenty minutes, when immediately after the last application the cataract was removed by Graefe's method modified. The eye was particularly unsound, since when the counter puncture was made vitreous was seen to present, but by careful manipulation no vitreous was lost, and it is believed that the use of the drug assisted materially in preventing such a disaster. There was a noticeable absence of congestion of the conjunctiva, and scarcely a drop of blood was lost in the section of the cornea, and none in doing the iridectomy. The perfect control of all the movements of the eyeball with the absence of spasmodic action of the muscles, as occurs when the operation is done without any anæsthesic, was observed, and assisted in the manipulation necessary to the expulsion of the lens.

Case II. C. J. B. got a piece of emery in his left eye twenty-four hours since. Did not stop work. Eye pained him last night. There was marked pericorneal injection, photophobia, lachrymation, and spasms of the lids. The emery was imbedded near the centre of the pupil in the corneal substance proper. A drop of a one per cent. solution of hydrochlorate of cocaine was instilled ten times at an interval of about one minute, when the foreign body was removed without pain and so easily that he hardly believed the emery had been removed. Atropia was applied, and he was ordered a collyrium containing atropia to be applied, eye to be protected, and to stop work. The eye felt so much better at once and continued to do so that he went to work, and on the second day I was called and found swelling of the lids, chemosis of the conjunctiva, and quite a collection of pus in the cornea at the point where the emery had been removed. Under appro-

priate treatment these unfavorable symptoms were readily changed, but the case is cited to show how the use of cocaine may lead the patients to disregard the instructions given them and lead them to be much more careless than though there had been some pain experienced in the operation.

The drug has been used in various other operations upon the eye and has quite fully come up to all that has been claimed for it. In the removal of polypoid growths from the ear, nose, and naso-pharynx, it has been found of great assistance, since by its use manipulations in these parts are much more readily borne, and therefore much more easily accomplished.

E. E. HOLT, M. D.

PROFESSOR PETTENKOFER ON THE CHOLERA BACILLUS.

BERLIN, *October* 18, 1884.

MR. EDITOR, — I take the liberty to inclose to you an extract from an address delivered October 15th, in Munich, by the eminent Professor Pettenkofer, before the Medical "Verein" of that city. The address was made in reply to an article by Dr. Frobenius upon the subject of cholera viewed in the light of recent studies and clinical observations, in which the bacillar nature of the infection was maintained.

Professor Pettenkofer said: "I think that we all have ample cause for renouncing the 'contagionist' theory in relation to the spread of cholera. We have been led to squander millions of money without apparent benefit by following these delusive theories. (Italy already regrets her sanitary regulations, etc.) I openly announce that I am forced to sustain and defend my former opinions in regard to the 'localization' of this disease, and I do this with the more confidence and the greater positiveness from the fact that the investigations of Koch have not succeeded in establishing any evidence against their correctness.

"The time is now fully come when the experiment should be made to determine whether the comma bacillus of Koch is capable of producing true cholera. The attempts which have been made upon animals have not been successful. *I freely offer myself for this purpose, and am ready to swallow bacilli which have been cultivated by Koch himself*, provided that no local or temporary conditions exist at the time of the experiment, such as the presence of cholera in the city, etc., by which the results of the trial might be rendered valueless. War has been waged and human lives sacrificed for a less worthy cause than this. *Here the noble object to be attained is so evident that the life of one individual* appears of little importance. My example, which, as I repeat, I freely and willingly make, will find followers. It will not be difficult to find twenty physicians who will offer themselves to confirm my view. Hundreds will follow these, until from the mass of accumulated evidence a correct judgment may be reached. (Professor Pettenkofer also declared his willingness to prepare for the experiment by first inducing a gastric and intestinal catarrh before introducing the bacilli.) I estimate Koch very high as a bacteriologue, and fully recognize his ability in the highest degree, but I must combat the conclusions to which he has arrived."

Very truly yours,

ALBERT N. BLODGETT, M. D.

Miscellany.

AN UNUSUAL CASE OF RABIES IN THE HUMAN SUBJECT.

THE London *Medical Record* condenses from the *Revue de Medicine* for August the details of a case recorded by M. de Beurmann of a woman who died in twenty-four hours from hydrophobia under extraordinary circumstances. The patient was forty-three years of age, and sixteen and a half months before she was attacked had lost by undoubted hydrophobia her favorite spaniel, which, as soon as the disease was confirmed, was kept in durance until its death by M. Bourel, a veterinary surgeon, who vouches for the fact that the animal was unmistakably rabid. The case as reported by M. de Beurmann presents interesting peculiarities upon three points. Firstly, the extremely long period of incubation — upwards of sixteen and a half months since the inoculation — was proved by the fact that the animal died fully that period before the development of the confirmed disease in the patient; and that, though after a lapse of time she ceased to think anything further of the inoculation or its consequences, she was careful in future to altogether avoid contact with dogs. The second noticeable point is the fact that, although the incubation was so long, the conditions were those which have hitherto been supposed to shorten the quiescent period; namely, mature age on the part of the patient, and a seat of inoculation near the nervous centre. In the case in question this was a sore on the upper lip which had been licked by the spaniel while suffering from early symptoms of the disease, the nature of which was then unknown. In this latter connection the author also refers to a case of M. Landouzy, where, although the patient was bitten in the cheek close to the eye, the symptoms were sixty-eight days in declaring themselves, whereas in three cases recorded by the same author, when the patient was bitten in the hand, symptoms appeared in sixty, forty, and thirty-nine days respectively. The third point is one which leads the author to a hypothesis having undoubtedly strong support from analogy. He points out that, though distinctly hydrophobic symptoms did not appear for sixteen and a half months after inoculation, the patient's history shows psychic disturbance and alteration in character for upwards of five months previously. She had become restless, irritable, emotional, anxious, had lost her appetite and power of sleep, and given herself up to exaggerated religious observances. She quarreled with her workpeople, was anxious out of all proportion to her responsibilities, and was a prey to extreme fatigue and agitation for some time prior to the pharyngeal spasm which marked the onset of the disease. The author points out that M. Roux, in his thesis upon hydrophobia, calls attention to the singular manifestations at times afforded by rabid patients, more particularly when the inoculation is intravenous. They may be limited to local or general paralyses, to convulsions, to incessant itchings without presenting any of the ordinary symptoms of hydrophobia of either the furious or the morose type. On this point M. de Beurmann adds: "It would be interesting to note with care the very numerous cases in which the bite of rabid animals is not followed, at least apparently, by any effect. Possibly attention directed to the victims might disclose in their manner some unwonted symp-

toms referable to rabies, and the existence of such abortive symptoms might lead to a belief in the existence of slight or spontaneously curable cases." Further, he says: "From this point of view it is of equal importance to ascertain if, in cases of very prolonged incubation, such as the one which forms the subject of this paper, the onset of confirmed symptoms be not preceded by a series of prodromata more or less premature. These premonitory accidents would so far shorten the apparent period of dormancy of the virus, and would greatly facilitate the true understanding of these extraordinary cases." The reporter, while admitting the ingenuity and probability of the author's hypothesis respecting the shortening of abnormally long periods of incubation by the supposition of at present ill-understood prodromata, points out that in this case the patient's lip, at first inflamed, after cauterization with nitrate of silver cicatrized regularly, and remarks that cauterization, insufficiently extensive and powerful to entirely destroy the virus, should not be completely ignored as a *possible* factor in the lengthening of the dormant stage.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 8, 1884.

Deaths reported 2443: under five years of age, 825; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 544, consumption 366, lung diseases 268, diphtheria and croup 240, diarrhœal diseases 102, typhoid fever 78, scarlet fever 36, malarial fevers 35, measles 23, whooping-cough 13, cerebro-spinal meningitis nine, erysipelas eight. From *malarial fevers*, New Orleans 13, New York seven, St. Louis six, Baltimore five, Philadelphia two, Chicago and Charleston one each. From *scarlet fever*, Chicago nine, New York seven, Boston five, Philadelphia four, District of Columbia three, Fall River and Cambridge two each, Cincinnati, New Orleans, Newton, and Newburyport one each. From *measles*, Cincinnati 14, New York eight, Fall River one. From *whooping-cough*, New York seven, Philadelphia and Chicago two each, St. Louis and Cambridge one each. From *cerebro-spinal meningitis*, New York and Boston two each, Philadelphia, Chicago, New Haven, Worcester, and Fall River one each. From *erysipelas*, Philadelphia and Boston two each, Chicago, Baltimore, and St. Louis one each.

One case of small-pox was reported in St. Louis; scarlatina 48, diphtheria 35, typhoid fever 30, and measles six in Boston.

In 94 cities and towns of Massachusetts, with an estimated population of 1,087,616 (estimated population of the State 1,955,104), the total death-rate for the week was 17.80 against 17.70 and 17.62 for the previous two weeks.

For the week ending October 25th, in the Swiss cities, there were 24 deaths from consumption, lung diseases 14, diarrhœal diseases 14, diphtheria and croup three, typhoid fever three, small-pox two, puerperal fever two. The death-rates were, at Geneva 16.3; Zurich 5.9; Basle 16.3; Berne 15.6.

The meteorological record for the week ending November 8th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM NOVEMBER 8, 1884, TO NOVEMBER 14, 1884.

BYRNE, C. C., major and surgeon. Granted four months' leave of absence from November 16, 1884. S. O. 265, A. G. O., November 11, 1884.

TREMAINE, W. S., major and surgeon. Granted leave of absence for one month on surgeon's certificate of disability. S. O. 233, Department of the East, November 12, 1884.

WILSON, WM. J., captain and assistant surgeon. Granted leave of absence for four months, with permission to go beyond sea, to take effect when his services can be spared by his department commander. S. O. 262, A. G. O., November 7, 1884.

SHUFELDT, R. W., captain and assistant surgeon. Assigned to duty as post surgeon at Fort Wingate, N. M. S. O. 217, Department of the Missouri, November 4, 1884.

OWEN, WM. O., JR., first lieutenant and assistant surgeon. Relieved from duty at Fort Canby Washington Ter., and ordered to Fort Spokane, Wash. Ter., for duty. S. O. 169, Department of the Columbia, November 4, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY DURING THE WEEK ENDING NOVEMBER 15, 1884.

BEARDSLEY, GROVER S. Promoted to the grade of Medical Inspector, April 24, 1884. November 14, 1884.

HEFFENGER, A. C., passed assistant surgeon. Duty at Portsmouth, N. H., continued till December 12, 1885. November 11, 1884.

WIEBER, F. W. F., assistant surgeon. To the Receiving Ship Vermont, at New York. November 12, 1884.

MEDICAL GRADUATES.

THE following gentlemen received the degree of M. D. at Dartmouth College, November 11, 1884: —

Charles Abbott Blake, Massachusetts; Willis Elmer Bowie, New Hampshire; Edward Clark Russell, Vermont; Walter Corliss, Maine; Oliver Austin Everett, Massachusetts; Onslow Allen Gordon, Massachusetts; Henry Carroll Holbrook, Vermont; Almon H. Keach, New York; Charles Edward Lovell, Massachusetts; Frank Constant Manchester, New Hampshire; Frank Eugene Mayberry, Maine; Angus Oster Patton, Canada; Charles John Peirce, New Hampshire; Frank Fletcher Pope, Massachusetts; Ellsworth Elbridge Shaw, Maine; Horace John Soule, Massachusetts; Frank A. Verrill, Maine; Charles Stuart Willis, New York; Andrew Reginald Wentworth, Maine.

SPECIAL MEETING OF THE BOSTON MEDICAL LIBRARY ASSOCIATION. — A special meeting of the Boston Medical Library Association will be held at the Library, Tuesday, November 25th, at 8.30 P. M., for the presentation of a bust of the late Dr. J. Marion Sims. Dr. O. W. Holmes will receive the bust on behalf of the Association. After adjournment there will be a social gathering in the Reading Room.

O. F. WADSWORTH, *Clerk.*

APPOINTMENTS.

BOSTON CITY HOSPITAL. — Physician in the Out-Patient Department, Edward M. Buckingham.

Physician to the Department for Diseases of Women, Charles M. Green.

DIED, — In Northampton, Mass., November 16, 1884, Samuel Augustus Fisk, M. D., M. M. S. S., and Ex-President of the Society, aged sixty-three years.

BOOKS AND PAMPHLETS RECEIVED. — A Manual of Dermatology. By A. R. Robinson, M. B., L. R. C. P. & S. Edin., Professor of Dermatology at the New York Polyclinic, etc. New York: Bermingham & Co. 1884.

Micro-Organisms and Disease. An Introduction into the Study of Specific Micro-Organisms. By E. Klein, M. D., F. R. S. With 108 Engravings. London: Macmillan & Co. 1884.

Transactions of the Colorado State Medical Society at its Fourteenth Annual Convention, held in Denver, June, 1884. Denver.

Asiatic Cholera in North America. National Conference of State Boards of Health. Held at St. Louis, October 13–15, 1884.

Practical Recommendations for the Exclusion and Prevention of Asiatic Cholera in North America. An Address delivered at the Opening of the National Conference of State Boards of Health. St. Louis, October 13, 1884.

Comparative Physiology and Psychology. A Discussion of the Evolution and Relations of the Mind and Body of Man and Animals. By J. V. Clevenger, M. D. Chicago: Jansen, McClurg & Co. 1885.

Jequirity: Its Uses in Diseases of the Skin. By John V. Shoemaker, A. M., M. D. Extracted from the Transactions of the Medical Society of the State of Pennsylvania for 1884. Philadelphia. 1884.

Jewish Hygiene and Diet. The Talmud and various other Jewish Writings heretofore Untranslated. By Carl H. von Klein, A. M., M. D. Delivered before the Annual Meeting of the American Medical Association at Washington, D. C., May, 1884.

SUNSTROKE. CHRONIC MENINGITIS.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.[1]

BY H. C. WOOD, M. D., LL. D.,
Professor of Nervous Diseases in the University of Pennsylvania.

GENTLEMEN, — The first case that I show you to-day is one of sunstroke. The following is the history: "J. W., age twenty-five, born in Ireland, has been in this country about two years. He has always been healthy, with the exception of bronchitis, which he has every fall. He denies having had venereal disease. He has always been a heavy drinker, and often gets drunk. For two weeks previous to admission he had been drinking very hard. On the 6th of September he was working on the University grounds. With the exception of the effects of his spree he felt as well as usual. About ten A. M. he began to feel weak and dizzy, but continued at work. These symptoms increased, and at half-past eleven he fell unconscious, and was brought to the hospital."

This case presented the symptoms usually seen in sunstroke. This condition is to be differentiated from heat exhaustion. In the latter the symptoms as a rule develop more gradually. The loss of consciousness is usually not so complete, and if the skin is examined it will be found cold and clammy, whereas if, in a case of true sunstroke, the hand be placed on the surface, or the thermometer be introduced into the rectum, it will be found that the patient is burning hot. The sudden onset, the complete loss of consciousness, and the high temperature distinguish this as a case of true sunstroke.

It is, of course, possible to have these symptoms occur in a case of apoplexy. There may be sudden loss of consciousness with high temperature in apoplexy, but very rarely does the temperature go up as rapidly as it does in sunstroke. In apoplexy the temperature may ascend two, three, or four, or more degrees, according to the seat of the clot, but the rise occurs in a few hours instead of a few moments. The completeness of the recovery, so far as the general symptoms are concerned, shows that this was a case of sunstroke and not one of apoplexy. In any case you should at once look for symptoms of a local lesion. You see whether or not the face is drawn to one side, or a leg has lost its power. If in a case of supposed sunstroke it is found that there is a *gradual* rise of temperature, with a distinct and decided loss of power in one part, there is good reason for making a diagnosis not of sunstroke but of apoplexy. This matter is of some importance, for I have seen sunstroke diagnosticated as apoplexy with fatal consequences. The distinctive symptoms of sunstroke are, the suddenness of the onset, the completeness of the loss of consciousness, and the high temperature without local palsy.

The next point in the history of this man to which I shall call attention is that there were some prodromes before the appearance of the unconsciousness. It is commonly thought that sunstroke comes on a man like a lightning flash out of a clear sky, and that under its influence a man drops at once; but I believe that in the majority of cases there is some indication of the coming danger — that there is a little cloud, although it may be no bigger than a man's hand, showing the approach of the coming storm. The prodromes which may precede the sudden onset and fully formed stage of sunstroke may consist, as they did in this case, simply of dizziness and a general feeling of wretchedness, or they may take a more specific type, and there may be headache, flashes of light, especially changes in coloration in the landscape, or there may be a flash of color blindness, or rather a flash of color-seeing. Clouds of yellow, and especially of red, float before the eyes. These are very characteristic of the approach of sunstroke. In the present case the prodromes seem to have been limited to dizziness and weakness, and as he now tells me, to an absence of perspiration. Here is a practical point in regard to prevention, which I shall allude to at this point. When a man, who is working in the hot sun, or in a hot boiler room, or in the evaporating room of a sugar refinery, or in any place where he is exposed to heat, does not sweat and begins to have some symptoms of cerebral difficulty, he is in danger of sunstroke. Under such circumstances it will generally be found that if a thermometer is placed under the tongue the temperature is two or three degrees above the normal, and the man is in the first stage of a disorder which may well be called thermic fever. At this time a cold bath, or simply going into the cool air, may relieve the condition. Every one who is exposed to heat should know that when there is lack of sweating, associated with general distress or disturbance about the head, he is in danger of sunstroke, and should at once give up his work.

There is another practical point to be drawn from the history of this case, and that is that the man whose system is weakened by the habitual use of alcohol, or by the recent excessive use of alcohol, is in a bad condition to resist the action of heat; this condition depresses the nervous system, and is a very strong predisposing cause to the occurrence of sunstroke.

This patient after suffering from the prodromes mentioned suddenly became unconscious. What was the cause of the sudden unconsciousness? The explanation is, I think, not difficult to understand. I cannot to-day give an elaborate discourse on the pathology of fever, but remember that the essential cause of elevation of the temperature of the body is the paralysis of certain cerebral nerve centres, which centres have for their function the inhibition of the production of animal heat. If these centres are paralyzed there is a rapid and enormous development of heat. What happens in cases of the character of the one before us is that the temperature of the body rises continually until finally a point is reached when this nerve centre is paralyzed, and there is nothing to restrain the development of animal heat, and suddenly every part of the body begins to develop heat. If the temperature curve could be registered in such a case, it would be found that a temperature which had been 103° F., 104° F., or 105° F., suddenly goes up to from 109° F. to 112° F.

Remember, gentlemen, that sunstroke may be developed under almost any circumstances, provided there is external heat, especially heat of a moist kind. It may develop at night under the heat of the tropics. It may develop in a patient with typhoid fever, rheumatism, or other disease in the hospital ward. Then there is a complicated condition.

The notes of this case go on to say that when brought to the hospital the temperature in the rectum was 110° F. The man was completely unconscious and

[1] Reported by William H. Morrison, M. D.

vomiting incessantly. The evacuations were voided involuntarily. There was slight twitching of the general muscles which later increased to decided, although not severe, convulsions. One of the most striking features of the case was the blueness of the surface of the skin and the almost complete arrest of the capillary circulation. I was not in the city at the time this man was brought to the hospital, but I have no doubt that if I had entered the room where he was I should have diagnosticated sunstroke at once from the odor. The odor of sunstroke is as distinct and as unmistakable as is the odor of typhus fever, small-pox, or any other disease. It is especially marked where there has been involuntary evacutions. Not only does the body give out this peculiar odor, but the stools lose their true fæcal smell in this peculiar, characteristic odor. The cause of this odor I do not know. It is, of course, dependent on the production in the secretions of some peculiar principle, the result of disturbed innervation. You must remember, gentlemen, that there is a close connection between nutrition and innervation. I have had under my care for years a patient in whom at one time, when out of health, a long walk would produce excessive fetor of the body which, while perceptible in all parts, was especially marked in the breath. The odor was evidently due to the production of a sulphur compound, for any article of jewelry that she wore at the time would be blackened by the formation of a sulphide. There was, in a word, the production of a fetid odor containing a peculiar sulphur compound of some kind, whose formation was dependent on lack of nerve power, or nervous exhaustion. In the same way there is developed in sunstroke, as a result of failure of nerve power and altered nutrition, a peculiar, unknown principle, which may be recognized by its odor.

In sunstroke, especially if the case has persisted for any length of time, other symptoms besides those I have mentioned appear. The first manifestations are due to over-heating of the brain, but afterwards symptoms due to disordered state of the blood develop. If the blood of a patient dead from sunstroke is examined it will be found to be liquid, and will not present the natural hue. It does not coagulate on exposure to the air, or perhaps there form in the blood little soft jelly-like masses, which are imperfect attempts at coagulation. The secretions are affected in sunstroke. At first there is dryness of the skin, but later the patient may become bathed with a fetid perspiration. The urinary secretion is lessened and finally arrested, and if the development of the case has not been prevented by proper treatment uræmic symptoms often appear. I mention these facts because they have an important bearing on the treatment. Although the early treatment of sunstroke is a very simple matter, the management of the case after the condition has lasted for some time may be one of considerable perplexity, for then you do not have simply the original trouble to treat, but also the damage which has been done by the original attack.

The marked blueness of the surface and the lack of circulation, which is referred to in the notes of this case, is a common symptom, indicating failure of heart power. The excessive heat, which weakens and finally paralyzes the nerve centres, also lessens the functional activity, and at last destroys the life of the heart, and weakens and eventually palsies the muscular fibres in the capillaries. The gland cell, the nerve cell, the muscular fibre, and all other forms of tissue were meant to run on a certain plane of constant temperature. If the temperature is elevated or depressed there is depression and finally paralysis of the function of the part. The blood stagnates in the capillaries partly on account of the failure of heart power, partly because the muscles of the capillary walls are unable to contract and expel the blood, and partly because the altered crasis of the blood unfits it for moving through the small vessels. The pulse in this condition, although it may be large, is soft and feeble, and often is very rapid.

In sunstroke one of the most important elements in the prognosis is the length of time that the symptoms have lasted. This man, fortunately for himself, was working on the University grounds at the time that he was attacked, and was brought to the hospital a few minutes after he had fallen unconscious. If he had dropped at some distance from the hospital, and had not been brought in for an hour or two, I do not believe that his life would have been saved. The symptoms which he presented were excessively severe for the first stage of sunstroke. If you can get hold of a case of sunstroke at once, and have command of the proper appliances, you can almost always save the patient, let the symptoms be as severe as they may. The presence of the capillary stasis mentioned in this case is always an important element in judging of the severity of the case. If such stasis has lasted for some time recovery is not probable.

The peccant thing, the *materies morbi*, in sunstroke is the heat. If this heat can be gotten out of the body the patient will recover, provided the high temperature has not produced organic changes. At first the condition is functional, but after a time the constitution of the blood is altered, the muscular fibre degenerates, and other organic changes are produced. Then, although the heat be withdrawn, the man may not recover consciousness, or if he does may have paralysis of some part or some injury to the glandular organs. Therefore, although you should usually give a favorable prognosis if the case is seen at once, yet if the symptoms be severe, and have lasted many minutes or hours, the prognosis becomes doubtful.

The indication for treatment is plain. It is to withdraw the heat. That method of treatment is the most effective by which the heat is most rapidly withdrawn. This man was very properly rubbed with ice. Although I say that this was perfectly proper, yet I do not consider it the best treatment for sunstroke. If the patient be covered in a bath tub with lumps of ice and a little water I believe the heat will be removed more rapidly than by rubbing with ice. In this case, under the application of ice, the temperature was in an hour and a half reduced to 102° F. With the ice-water bath I should have expected the temperature to be at 102° F. in a few minutes. It is important to bring the temperature down as rapidly as possible. After the temperature was lowered and the application of ice stopped reaction occurred, and the temperature again arose to 104° F. The man was placed in an ice-water bath, and the temperature fell to 101° F. A case to which I have referred on other occasions, but to which I again call attention in order to impress these things upon your minds, was that of a man who suffered from sunstroke at the Centennial Exhibition. I saw him immediately after the occurrence, and packed

him away in an ice-water bath, with large lumps of ice all around. He soon recovered consciousness, and thought that he was stored away as a corpse in an ice-chest. It was rather a novel experience, but it saved him from the ice-chest.

The cold applications should not be continued until the temperature reaches normal. If the temperature at the start has been 110° F., the man should be removed from the bath as soon as the temperature falls to 103° F. The best place to take the temperature is, of course, in the rectum, the next best place being the mouth. The axilla cannot be used because the peripheral temperature falls much more rapidly than does the internal temperature. The reason for stopping the application of cold as soon as the temperature comes within two or three degrees of normal is that very often it continues to fall after the external cold has been taken away, and the danger is that if the temperature be reduced too much it may fall below the normal. There is sometimes in sunstroke a tendency for the temperature to rise after it has been artificially reduced. Under such circumstances the hypodermic injection of quinine is of service, or if the local results be feared, the quinine may be administered by the rectum.

Another very important remedy to be used in these cases, especially where there is convulsive seizures, is morphia by hypodermic injection. One fourth of a grain of the sulphate should be given. In this case the notes state that after the reduction of the temperature digitalis was given on account of the failure of heart power, and with it was associated the deodorized tincture of opium. Bromide of potassium was given to control nervousness, although the man was constantly vomiting. Bromide of potassium should never be put in a stomach which is already irritated. If the stomach is engaged in rejecting everything which is put in it it will simply be encouraged in its evil way by the use of bromide of potassium. It was a proper remedy for the condition of the patient, but it was a very improper remedy for the condition of the stomach, and it was at once rejected by the stomach. It either should have been given by the rectum or substituted by something else. In this case the rectum would probably not have tolerated its introduction.

Soon after the temperature was reduced to normal the man regained consciousness, but the headache remained, and an ice-cap was very judiciously applied to his head. For a day or so there was an evening rise of temperature, but since then the temperature has been normal. There has been occasional slight headache. He is weak, and feels giddy on rising. Remember that this man is suffering not simply from the results of a sunstroke, but from the results of sunstroke superadded to those of a debauch. The symptoms are therefore a little different from those of an ordinary attack of sunstroke. Usually in the affection occurring in a person who does not use alcohol the local symptoms are more marked than the general. The local symptoms which are usually presented are headache, cerebral confusion or distress, and perhaps dizziness. This man had these symptoms only to a slight extent. He has had slight headache and dizziness on getting out of bed, but to these are superadded a condition of general weakness, which is partly the result of the disorder of the nervous system and of the blood wrought by the sunstroke, and partly the result of the exhaustion due to the excessive use of alcohol.

It is a matter of importance that the late symptoms of sunstroke should be properly treated. The most important sequela of sunstroke is chronic meningitis, which is often associated with chronic cerebritis, that is, chronic inflammation of the brain membranes affecting to some extent the gray matter of the brain. Hence the after-treatment consists in trying to prevent the occurrence of this inflammation. This man had slight symptoms of meningitis, in that for a day or two there were present throbbing headaches, and he was very properly put on the use of a mercurial.

There may be some cases of sunstroke in which it may be right to bleed a patient during the active stage of the attack. I have, however, never seen such a case. There are on record undoubted cases in which a man has fallen from sunstroke, has been freely bled, and at once recovered consciousness. In most of such cases the free bleeding has restored consciousness probably not so much by its direct as by its indirect influence. The running off of the hot blood rapidly lowers the temperature, and the man is relieved not because the unconsciousness was due to cerebral congestion, but because the removal of the blood has rapidly cooled the body. At the same time, if I had a case of sunstroke in a man with powerful, bounding pulse, throbbing temporal arteries, suffused face, and plenty of circulatory force, I might bleed, but I repeat I have never seen such a case.

After the patient recovers consciousness, if there be violent headache, bleeding, either local or general, is the thing to be done. Many years ago a prominent physician of this town had sunstroke. His first remembrance after recovering consciousness is of his father, who was also a physician, standing over him with a medical friend. He awoke with a splitting headache. He said to them, "Bleed me." They refused. He said, "Bleed me, or I shall die." They then bled him, and at once the headache was relieved, and all danger of future trouble was averted. That man was suffering from secondary cerebral congestion. If he had not been bled he would probably have been either immediately or secondarily disabled by cerebral inflammation.

During the past week I saw a young physician of Philadelphia who had sunstroke a week or ten days ago. He was in the city at the time, but on recovering consciousness went to the sea-shore. He then had excessively violent headaches. He went to several physicians and asked them to bleed him locally. They refused, and the headaches continued until he was attacked with severe bleeding from the nose, which was so profuse as to cause some alarm. The epistaxis occurred a second time, and since then there has been no headache. I believe that the epistaxis saved that man's life, or at least his mental organization. He was in the forming stage of a subacute meningitis. He ought to have been bled, and the physicians failing to do their duty, the mucous membrane of the nose fortunately being tender the man was bled by nature, and thereby his brain was relieved. The man has now perfectly recovered.

In the present case the symptoms of meningitis have not been such as to require active treatment. The man requires simply quiet, rest, and tonic treatment. In these cases tonic treatment should not be resorted to too early. The danger is not from weakness, for this will be recovered from in time, but it is from cerebral inflammation. It is better to let the man

remain weak for two or three months than by trying to rapidly raise him up start a fire in his brain.

After an attack of sunstroke it is imperative that the patient should avoid excessive heat for many months. In the early weeks following the attack he should avoid the glare of the sun, mental exertion, cerebral excitement, and everything that would tend to increase the danger of meningeal inflammation.

CHRONIC CEREBRAL MENINGITIS.

This man states that for the past three months he has suffered from a steady pain in the head, which occupies the vertex and is fixed. Its severity is at times increased. Previous to four months ago he considered himself to be in his ordinary health. Since the appearance of headaches he has had vertigo and some numbness along the inner sides of the legs. There has also been some alteration in his disposition and some loss of memory.

Without going further into the history you can see at once that there are present symptoms of meningitis. There is a persistent severe pain in the head, a certain amount of alteration of disposition, loss of memory, and giddiness; there is also a diffused irregular numbness in certain parts of the body. In this instance we have the symptoms of cerebral meningitis. These symptoms also occur in brain tumors, but tumors are very often associated with cerebral meningitis, and it is sometimes impossible to diagnosticate tumor from meningitis if there be no symptoms of localized trouble. If with the symptoms of meningitis we found some local paralysis, a facial monoplegia for instance, or certain localized convulsions in one part of the body, or if there were persistent clearly localized numbness, we should have more reason for believing that the man was suffering from tumor. There may be a tumor associated with this meningitis, but the symptoms are clearly explainable on the supposition that the man has meningitis. The peripheral gray matter is supplied with blood from the brain membrane, and therefore when there is disturbance of the circulation of the membranes there is disturbance of the gray matter. I believe that you never have pain in the head as the result of pure disease of the gray matter unless the disease be of such nature as to alter the pressure in the brain. This man has evidently meningitis or a tumor, but the probabilities are in favor of the former condition.

Having arrived at this conclusion so far as the disease is concerned, the next thing is to search for the existence of a cause. The three most common causes of chronic meningitis in the non-tubercular adult are injury, sunstroke, and specific disease. A case of non-tubercular subacute or chronic meningitis not the result of one of these three causes is excessively rare.

The notes of this case state that the man met with an accident some months ago in which he had three ribs broken, but he is not certain that he was struck on the head. He was unconscious for a few minutes after the injury. He was in the hospital under treatment for some time. On leaving the institution he noticed severe headache accompanied with great vertigo. He also gives a history of two sunstrokes, one occurring in 1856 and the other in 1862. Since the last attack he has had headache off and on, but not so constantly as since the accident. He also acknowledges having had venereal disease thirty-five years ago. We have, then, all three causes of meningitis present in this case.

Is there any way by which we can determine the rôle which sunstroke plays in the production of these symptoms? I think there is. We must investigate as to the rapidity with which the headache followed the sunstroke. The headaches which he has had since shortly after the last sunstroke have not been very decided nor very steady, and I think that it is perfectly plain that the sunstroke could not have set up a genuine meningitis. This man has not been incapacitated from following his trade as a carpenter. Has been able to work out-doors during the hottest summer weather. This would not have been possible had he had a meningitis lasting for twenty-two years. The sunstroke may have produced a condition of impaired nutrition of the brain and a weakening of the vessels, which would render them less resistant to any cause which would produce inflammation.

When we come to the question of the rôle played by the venereal sore and the accident, we come to a question which cannot be positively settled. I think that it may be considered well established that when a man has a venereal taint the local manifestation of that taint may be decided by an accident. Such a person receives a blow on his shin, and he has a periostitis excited by the blow, but the inflammation is of the specific type. If the same person had received the blow on his skull he would have had an inflammation of a specific type set up in that locality. There are one or two reported cases in which cerebral syphilis has in the same way followed sunstroke. The sunstroke has been the exciting cause, — the match which has fired the gunpowder which was there all ready to be exploded.

Again, the injury was of itself possibly sufficient to account for the meningitis without the existence of a venereal taint. The man evidently received a severe blow on the head. Ordinarily, however, a blow which produces only a few minutes' loss of consciousness, as happened in this case, does not result in inflammation. While we cannot say positively, then, that the syphilis has had anything to do with the occurrence of the disease, it is very probable that it has, and that there is a specific meningitis started by the local injury, although it is possible that the injury may have been the sole cause of the attack.

The treatment in this case will consist in the administration of iodide of potassium in amounts sufficient to produce iodism. Even in cases where there is no reason to suspect specific taint the use of iodide of potassium, associated with counter-irritation, is the best plan of treatment of chronic meningitis.

— The people of British Columbia are becoming alarmed at the negligence shown by the government in not providing suitable isolated quarters for the Chinese lepers at present confined in the jail at Victoria. At the last meeting of the city council it was moved and carried that the provincial government be requested to communicate with the dominion government with a view to have the necessary steps taken for the erection of a leper hospital. The mover knew of several cases, two of which were in the city jail. The Chinese doctors of the city believe the disease to be so contagious that the people are liable to catch it by inhaling the breath of a leper, and the mover believed that many young men had caught the disease by smoking cigars made by Chinese lepers.

SUMMARY OF SIX HUNDRED CONSECUTIVE CASES OF MIDWIFERY.[1]

BY W. W. WELLINGTON, M. D., CAMBRIDGEPORT.

Natural Labor. Four hundred and fifty-six cases; about seventy-five per cent. Under this title are included all cases in which the head presented, and in which there was no occasion for instrumental or manual interference in the delivery either of the child or of the placenta, and no serious post-partum hæmorrhage. A few of the cases were protracted beyond twenty-four hours.

Face to Pubes. Seventeen cases. Twelve of the cases of natural labor presented this peculiarity, and are included under that head; four were in cases of instrumental labor, and one was in a case of twins.

Rupture of Perinæum. Thirty-eight cases. Thirteen occurred in instrumental labors. All were sutured, and in all but five the edges united.

Breech Presentations. Nineteen cases.

Footling Cases. Two.

Knee Presentation. One.

Instrumental Cases. Eighteen. All by forceps. Perforation of head not required in any case.

Turning. Six cases. In one of these cases the head was at brim of pelvis with face to the front; child still-born.

Convulsions. Eight cases. Seven mothers recovered. The eighth recovered from the convulsions, which occurred at the end of the seventh month, but nine days afterward she had hæmorrhage from partial placenta prævia, and was delivered by turning. She died five days after from septicæmia. Three of the babies were still-born.

Twins. Nine cases.

(1.) A boy weighing ten pounds, and a girl six pounds. Both breech presentations. Second child was born enveloped in its membranes, and immediately following it both placentæ.

(2.) In one head presented; in the other the feet. Placentæ were separate. Considerable hæmorrhage.

(3.) Both still-born. Both head presentations, the last being face to pubes. Placentæ united.

(4.) A boy weighing eight pounds, and a girl weighing six pounds. Both born before my arrival. Both were reported as having been head presentations. Placentæ were united.

(5.) First child, breech presentation; second, head. Placentæ united. One of the umbilical cords had in it a loose knot.

(6.) Both head presentations.

(7.) One born before my arrival; the other lay crosswise, and was delivered by turning. Placentæ separate.

(8.) Seven months' children. Both head presentations. Placentæ separate.

(9.) First baby (breech presentation), pains dying away, was delivered by pulling down feet. Second baby (breech presentation also) was delivered in the same way. Placentæ not following in a reasonable time they were peeled off (they were united) and extracted. Severe after-pains followed, succeeded by fainting. Found uterus full of clots, and removed them. In doing this an irregular contraction was discovered in upper part of uterus, the upper chamber containing a piece of placenta; removed it. Uterus then contracted, and there was no more flowing. Ergot was given during these transactions, also rum, this being the only liquor at hand. Mother and children did well.

There were seventeen cases of retention of the placenta; nine cases of excessive hæmorrhage after delivery of placenta; and two cases of what seemed to be partial separation of the placenta before the delivery of the child.

In the cases of retention the placentæ were removed manually. The majority of them resulted from irregular contraction of the uterus. In a few there were morbid adhesions.

The cases of hæmorrhage after the birth of the placenta were treated mainly by emptying the uterus of coagula, pressure on uterus to secure its contraction, and giving ergot and stimulants.

The two cases of probable separation of placenta before the birth of the child may be worth particularizing.

(1.) The woman flowed several times during the last six weeks of pregnancy, sometimes passing large coagula. Placenta prævia was feared. No portion of placenta, however, was over os. The birth of the child was easy, but a large discharge of blood followed immediately, and the woman became faint. The placenta came away naturally.

(2.) Labor at full term. Pains began at five A. M. At nine A. M. I visited the patient, and learned that for an hour or more she had had fainting turns. Pains were good, the os was dilated, and membranes were protruding. Fainting turns continued. Pulse became slow and feeble. I ruptured the membranes, and the baby was soon born. The exit of the child was followed by a large gush of blood. The child was dead. Introduced hand into uterus, found placenta detached, and delivered it at once. Uterus contracted and hæmorrhage ceased. Severe after-pains followed.

One other case of interest may be mentioned. The labor was natural; four hours in duration. On the seventh day after delivery, in consequence, apparently, of undergoing considerable excitement, uterine hæmorrhage came on. This subsided the next day. On the ninth day it came on worse than before, making it necessary to empty the womb and give ergot. The bleeding again ceased. The next day the hæmorrhage returned, but soon subsided, and uterus could be felt well contracted. On the thirteenth day after delivery the bleeding recommenced and continued till the next day, when a solution of ferric alum was injected into the uterus. This stopped the trouble.

Prolapse of Bladder. Two cases. Both appeared as smooth, fluctuating swellings before the advancing head. In each case the catheter introduced into the urethra could be traced into the swelling. The urine having been drawn off the bladders were pressed up, and as the heads advanced they disappeared.

Placenta Prævia. Three cases; all partial.

(1.) Patient seven months pregnant. Slight flowing at intervals for a fortnight; rather severe for six hours. Edge of placenta was separated from its attachment, the head of child descended, and the hæmorrhage ceased. Child still-born.

(2.) Labor three weeks premature. Flowing came on followed by pains. Os partially dilated, and edge of placenta could be felt. Head could also be felt,

[1] Read before the Obstetrical Society of Boston, October 11, 1884.

which slowly descended, and hæmorrhage gradually ceased.

(3.) When seven months pregnant had three convulsions, the urine being albuminous. Nine days afterward flowing came on, followed by labor pains, and partial placental presentation was discovered. Child was delivered by turning. Woman died three days after of septicæmia.

Prolapse of Umbilical Cord. Two cases. In each case cord was found prolapsed on arrival and with no pulsation. Both babies still-born.

Spina Bifida. Two cases.

Thrombus of Labium. One case. The labor was normal. A thrombus of left labium was discovered the next day, severe pain having been felt in external organs since the previous afternoon. Labium was everted; color was livid; the parts were very tender; discoloration extended through perinæum and upon the nates. Distention was chiefly internal, nearly closing vagina. The effusion of blood was large. On the third day the thrombus ruptured, and a large amount of coagula was discharged. These coagula continued to be discharged for several days. The woman suffered but little pain. On the ninth and tenth days there were headache and febrile disturbance. On the nineteenth day the cavity was contracting with slight purulent discharge. On the thirtieth day the patient reported herself as well.

Phlegmasia Dolens. Six cases.

Cystitis after Delivery. Four cases. One of these cases was a severe one, lasting three months. The woman was delivered by forceps. The perinæum was lacerated to sphincter, and there was also a serious laceration of the cervix. The cervix had been much elongated and thinned during labor, having been pushed along before the vertex, and with difficulty kept back as the vertex advanced. The laceration was discovered while wiring the perinæum. Both perinæum and cervix healed well.

Ophthalmia Neonatorum (purulent) occurred in two cases. Both cases recovered.

Two acephalous monsters.

The Umbilical Cord was wound round the neck of the child twice in two cases, and three times in one case, so tightly that it had to be cut before delivery could be effected. In neither case could the cord be carried over the head or the shoulders.

Septicæmia. Three cases. One died, and two recovered. In neither case were antiseptic injections made into the womb.

Vesico-Vaginal Fistula. One case. The labor was natural, lasting about sixteen hours. A fistula manifested itself on the third day after labor, much to my surprise. There seemed no sufficient cause for its existence. An operation was performed for its cure with partial success. The woman would not consent to a second operation, and I afterwards lost sight of her.

Deaths. Five in number.

(1.) Metritis followed by puerperal mania. Died at end of second week.

(2.) Convulsions at seven months. Urine scanty and albuminous. There were only two. Nine days after there was uterine hæmorrhage, caused by partial placenta prævia. Child was lying crosswise. Os was dilated, membranes were ruptured, and delivery was effected by turning. Five days afterward the woman died of septicæmia.

(3.) Died of puerperal peritonitis.

(4.) Died eight days after labor, and after two days of terrible dyspnœa from valvular disease of heart, which had afflicted her for a considerable time before her labor.

(5.) In the midst of a severe attack of pneumonia, patient being at full term of pregnancy, labor pains began. At the end of twelve hours, the pains slackening, and the head lying low in the pelvis, the forceps was applied, and delivery was effected. No bad puerperal symptoms followed, but death resulted from pneumonia six days after labor.

If the last two cases be deducted, in one of which death resulted from valvular disease of the heart, and in the other from pneumonia, the number of deaths will be three, or one in two hundred.

CASE OF EXTRA-UTERINE PREGNANCY. RUPTURE; PERITONITIS; RECOVERY.[1]

BY E. E. MONTGOMERY, M. D.,
Obstetrician to the Philadelphia Hospital.

MARCH 19, 1884. Mrs. M. has had four children and two miscarriages, the last miscarriage occurring some four months since. She has for several years suffered from chronic phthisis. Menstruation was absent for two periods, but two weeks ago she had a bloody discharge for several days. Although she had been suffering from the phenomena usual to her in early pregnancy she then concluded that she was not pregnant.

On the 18th, after a fright, she was taken with severe pain in the right side, which, continuing to grow worse, was attended by frequent micturition, a sensation in the pelvis of weight or bearing down, intermittent vomiting, and a serous vaginal discharge. Her husband called at three A. M. to-day (March 19th), informed me she had cramps, and asked for a prescription for her relief. I gave a prescription containing morph. sulph., one eighth grain to each dose, to be given every two hours until relief.

I saw her at eight A. M., when she was quite pale, complaining still of pain in the right inguinal region. As I had a clinic at nine A. M. I made a hurried visit, injected morph. one fourth grain, hypodermically, and ordered ℞ quin. sulph., two grains, ext. opii, one half grain, in pill, every three hours.

Five P. M. Pain somewhat relieved; stomach very irritable, would retain nothing; pain greatly increased by vomiting; face pinched, pale, and anxious looking; lips bloodless; pulse 90. Bimanual examination disclosed the uterus slightly enlarged and retroverted. Douglas's cul-de-sac presented a mushy or doughy sensation. On the right side could be felt a small, irregular-sized mass, which was diagnosticated to be an escaped fœtus from a tubal pregnancy. The pills were discontinued, and ext. op., one grain, in suppository, substituted, to be given every six hours, and an alkaline mixture and one half fluid ounce each of milk and lime-water were given every three hours by the stomach.

March 20th. She slept poorly, but does not suffer so much from pain. There is marked tenderness over the lower part of the abdomen, more marked upon the

[1] Read at a meeting of the Philadelphia Clinical Society, October 24, 1884.

left side. Examination per vaginam. The mass is felt posterior to the uterus, and is quite hard and tender upon pressure. The uterus is fixed. Pulse 90. Vomited once. She has been kept perfectly quiet. The bladder relieved by the catheter. ℞ quin. sulph., five grains, ext. op., one and one half grains, in suppository, every six hours.

March 21st. General condition better, though she slept but little. The introduction of the suppositories was attended with so much pain that they were discontinued, and morph. sulph., one sixth grain, with quin. sulph., two grains, given every three hours by the mouth.

March 22d. Some sickness of the stomach. Pulse 88. Temperature normal. Very nervous; easily disturbed. Abdomen still tender to pressure. Returned to the use of the suppositories. Slept well last night after tr. op. deod., twenty-five drops, were given.

March 24th. Temperature normal. Pulse 80. Abdomen still tender, especially over the lower portion and left side. Movement attended with pain. The suppositories induced so much pain that they were discontinued, and tr. op. deod., thirty drops, given by the mouth every three hours.

Subsequent to this date the convalescence was gradual. She regained her strength very slowly. She left the city the latter part of July, returning about the middle of September again pregnant.

Upon examination a few days ago the uterus was found enlarged to the usual size at two months, and posterior to it could be felt a smaller mass, in which the remains of the former gestation were evidently encapsulated.

In such cases it becomes an important question to decide when we should proceed to surgical measures.

Notwithstanding the successful termination of this case I would not uphold the treatment as the one most likely to yield a favorable result.

Had the symptoms of shock and internal hæmorrhage persisted during the third day as upon the second it was intended to make an abdominal incision, remove the fœtus and effused blood, and ligate the bleeding vessels. Such a course, pursued with the advent of the characteristic symptoms, would, without doubt, decrease the mortality of the accident.

A CASE OF EXTRA-UTERINE PREGNANCY TREATED SUCCESSFULLY BY ELECTRICITY.[1]

BY JAMES SIBBALD, M. D.

MRS. R., aged thirty-four years, a woman weighing 107 pounds, of spare build and exceedingly nervo-bilious temperament, was married when twenty-one years of age, and had a miscarriage about five months subsequently, since which time (for thirteen years) she was never pregnant. although very desirous of becoming so.

Her menstrual periods were always regular and natural up to June 16, 1884, at which time there was no sign of menstruation. One week later she commenced feeling sick in the morning, and also complained of soreness, with decided tenderness on pressure, over the right inguinal region, which gradually increased in severity. At the same time bloody discharges would appear, with no regularity, every week or two, lasting from a few hours to several days.

On July 3d, while standing in the street dealing with her butcher, she was suddenly seized with a violent pain in the abdomen, which caused her to fall in the street. She was picked up and carried to her bed. Morphia was administered hypodermically and poultices applied for six days before the tenderness subsided. For the next three weeks there was more or less tenderness over the right inguinal region.

On August 4th (just one month after the first attack) she had a second attack of local peritonitis, which lasted five days. At this time she was sweeping the floor, when she suddenly fell, overcome by the severe abdominal pain.

After the acute symptoms of the first attack had subsided a vaginal examination revealed a soft mass on the right side of the uterus, very sensitive to pressure, and displacing that organ to the left. The sound was passed cautiously into the uterus a distance of over four inches without obstruction. These facts, in connection with the cessation of menses, morning sickness, some enlargement and soreness of breasts, with occasional bloody discharges from the uterus, warranted a diagnosis of extra-uterine pregnancy.

On August 18th Dr. Montgomery saw the case in consultation, and coincided in the diagnosis. He advised the destruction of the fœtus, which was now in about the eleventh week of gestation, by means of electricity. Eight applications of the battery were made, which had the desired result. The mass is slightly perceptible on examination at the present time, the womb being still displaced to the left side. Menstruation has returned twice since, being perfectly normal, and no inconvenience is now experienced.

RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M. D.

ON CHANGES IN THE NERVOUS APPARATUS OF THE INTESTINAL WALL IN PERNICIOUS ANÆMIA AND IN GENERAL ATROPHY.

SASAKI[2] has carefully studied the intestines coming from fifty autopsies, and in two, cases of pernicious anæmia, marked changes were found in the nervous plexuses. One of these cases corresponds closely with those already reported by Jürgens[3] and Blasko,[4] while the other presents different and further advanced lesions.

The method employed was as follows: Pieces of the intestine were preserved, part in alcohol, and part in Muller's fluid.

The examination of Meissner's plexus was comparatively easy. Bits of the mucous membrane were torn off with the forceps, and then the submucosa was carefully separated from the muscular coat. The pieces were placed for twenty-four hours in very dilute acetic acid (1 to 400) in order to clear up the connective tissue, washed for a few hours in water, stained with picro-carmine, and examined in glycerine.

Auerbach's plexus, on the other hand, presented

[2] Virchow's Archiv, Bd. 96, S. 287.
[3] Berl. klin. Wochen., No. 28, 1882.
[4] Virch. Arch., Bd. 94 S. 136.

more difficulties. Portions of the intestine were left for a day or two in a weak solution of bichromate of potash (0.5 of the salt to 200 c. c. of water). The muscular coat was laid bare as above. Then with the aid of fine forceps and a hand lens the bundles of the circular layer were separated from those of the longitudinal, which latter, in the case of adults, can never be torn off in sheets. In this way specimens could be obtained entirely deprived of the inner coat, and consisting only of the longitudinal fibres with the peritonæum and subperitoneal tissue. The net-work of nerves was found spread out upon this surface. They were then treated with acid, as the others, and colored. In the staining care was exercised to have the muscular coat come in contact with the fluid. This usually took from twenty to thirty minutes.

The Microscopic Appearance. In the normal intestine of the adult Auerbach's plexus presents itself as a net-work of large bundles of nerve fibres, with here and there accumulations of ganglion cells. The size of such ganglionic nodes varies greatly; it may reach 0.18 mm. The nerve cells are placed closely together, and have a length of from 0.014 to 0.032 mm. Their shape is either polyhedral or elongated, and they are composed of a finely granular protoplasm, in which is imbedded a distinct nucleus and nucleolus. Besides these are found at the points of intersection numerous small spindle cells which belong to the sheath of the ganglion. From these nodal points broad projections are thrust out, which consist of rows of nervous elements or branches of pale nerve fibres. The same small elongated bodies are also to be seen in these branches. The nerve fibres appear almost homogeneous.

The examination of the first case of progressive anæmia revealed an extensive change in all the nervous elements throughout the entire intestine. On the first inspection it appeared that the ganglionic cells of the plexus myentericus were separated by a considerable interval from each other, and were extremely small and deformed. The greater number reduced to one third of their normal size. The protoplasm was very granular, contained yeliow pigment, and the greater number were without nuclei. Many cells had a glancing, homogeneous appearance, and resembled those which have been described as "sclerosed," and which have been found after lead poisoning. Between such lay a pale, finely granular mass, which the author believes was produced by their entire destruction. The small spindle cells were diminished rather than increased in number, and no thickening of the connective tissue sheath of the enlargements could be detected. The nerve fibres were narrower, were finely granular, and had lost their capability of taking coloring material. Many could only be recognized by their longitudinally striated look and scattered nuclei. Besides the "sclerosed" cells there were found numerous glancing, homogeneous particles of different size (0.003 to 0.03 in diameter). These lay partly in the plexus, in the nerve bundles or near them, and partly isolated, between the muscular fibres. Some were round or oval, others resembled a ring surrounding a ball, but with no concentric arrangement; and in many still smaller granules were found. They stained but slightly with picro-carmine, resisted the action of acetic, sulphuric, or nitric acid; neither did they dissolve in ether or take on a peculiar color with iodine. From this they correspond with the substance which von Recklinghausen has called hyaline. These bodies were often present in the intestines of old people, but never so abundantly as in the cases under consideration. They seem to have a relation with the corpora amylacea, and like them are normally found in small numbers. Their presence in large numbers is associated with a chronic atrophic process. The question as to their origin is not easy to answer. The fact of the presence of granules of a similar substance in the spindle-shaped cells of the neurilemma points to them as a probable source.

In Meissner's plexus similar changes were found. Small, wrinkled ganglionic cells, with granular protoplasm, and without nuclei, separated from each other by abnormally large intervals composed of a fine granular mass. The nerve fibres were granular, and stained poorly.

In regard to the muscular coats it may be said that they appeared narrower, and the fibres were thin, and opaque from the presence of minute drops. Elongated nuclei were rare.

In the vessels there was no marked change beyond the diminution in the number of nuclei. The papillæ were small, short, and cloudy, the glands shrunken, and their cells disintegrated.

In the second case the intestinal wall was not especially thinned, yet there was found a marked fatty degeneration of Auerbach's plexus throughout the entire canal. The muscular fibres were also affected in the same way, but to a less extent. Osmic acid was especially useful in demonstrating this. The ganglionic cells were mostly destroyed, but here and there perfect ones were to be met with. In the nodal points the fat drops were irregularly distributed, and not always in association with cells. The nerve fibres were filled with oil globules. Meissner's plexus was less markedly implicated. Its cells had in many places lost their sharp contour, and even looked like mulberries. Very little fat was noticed. The villi were of normal size, but showed a parenchymatous degeneration. The vessels showed nothing abnormal.

If the literature of pernicious anæmia is compared in its ætiological, clinical, and anatomical relation it is found that the course is irregular, extending over periods varying from six or eight weeks to several years. From this it is easy to believe that the disease may arise from different causes and represents no single process. Lépine has distinguished three forms in regard to origin: —

(1.) Lienal (splenic) and medullary form.
(2.) Gastro-intestinal.
(3.) That occurring during pregnancy.

The author regarded his two cases as belonging to the second class, which includes about one fourth of all cases.

The question still remains to be answered, what relation do the anatomical changes in the ganglionic apparatus and the atrophy of the intestines have with the general anæmia? Are they to be considered as primary, or as a partial expression of the general affection? In order to obtain information on these points eighteen intestines, which were atrophied in consequence of cancer, phthisis, or old age, were examined. In these cases were also brown atrophy of the heart and liver, and a small spleen. In the intestines there was found a thinning of the muscular coat, with a granular clouding and pigmentation of the ganglion cells of both plexuses. Fat drops were only found in the cases of cancer, and were usually distributed in the periphery around the nucleus. The form of the cells was

never altered. This, then, is considered to be a fatty infiltration rather than a degeneration. From this it would appear that a simple atrophy does not produce a degeneration of the nervous apparatus of the intestine; therefore the changes in these cases are regarded as those of origin. In both cases, also, there were symptoms referable to the intestinal tract, such as pain, vomiting, and diarrhœa, which could have had a marked influence on the formation of blood.

Was the atrophy of a chronic catarrhal or neurotic nature? For the first, which according to Nothnagel is the most common, would appear the slaty discoloration in the ileum, the regular injection of the mucosa of the jejunum, and the small cicatricial depressions in the cæcum. But all these are often found unassociated with atrophy, and without producing any symptoms during life.

The conclusions which are drawn are as follows: —

(1.) It is highly probable that the gastro-intestinal form of pernicious anæmia may be produced by recognizable anatomical lesions in the intestine.

(2.) Pernicious anæmia can be caused by an atrophy of the intestines. The correlated change in the nervous apparatus coming under the class of parenchymatous degeneration.

(3.) In the affection of the intestine which is not diffuse, and does not extend over a large area, the changes in the plexuses are restricted in a corresponding manner.

ON TONSILS AND LYMPHATIC FOLLICLES.

This article is the first of a series by Stöhr[1] on the conglobate bodies called the "peripheral lymph glands." They differ from the lymph glands proper, which are interposed in the lymph current, on account of their situation and the relation which they bear to an epithelial covering.

The mucous membrane of the mouth and pharynx is marked in some places by the presence of closely aggregated leucocytes. These appear either in the form of more or less sharply bounded uniform infiltrations, or as the so-called follicles (adenoid tissue of His, cytogenous tissue of Kölliker, or conglobate gland substance of Henle). This tissue, in parts, assumes the shape of prominences, partly projecting into the pharyngeal cavity and partly sunk in the depth of the mucosa. These are often complicated by numerous infoldings, and thus are formed the follicles and tonsils (palate, tubal and pharyngeal tonsils). Stratified pavement epithelium covers the surface and follows it through all the furrows to their deepest parts.

If sections of the human tonsil, perpendicular to its surface, are studied it is often very difficult to follow this epithelium to the bottom of the clefts. At times extremely narrow prolongations can be detected. At others even this is impossible, and the typical cells seem to be replaced by elements which are identical with the round cells of the adenoid tissue. This, however, is not the case. The flat epithelium is always present in the same thickness (in places even thicker), but is so permeated by leucocytes that it is only by aid of very fine sections and successful coloring that its existence can be demonstrated. This infiltration may extend over the entire covering of a furrow and suggest the possibility of a pathological change. Usually it is much more restricted in its extent.

The appearances thus briefly depicted are the results of an extended migration of indifferent cells through the epithelium into the buccal and pharyngeal cavities. And far from being of a pathological nature, this is to be regarded as a normal process. And wherever accumulations of round cells lie directly beneath the epithelium great numbers of them find their way out and appear on the surface as mucous and salivary corpuscles.

Careful examination shows that the path which they follow lies in the cement between the epithelial cells, and that their nuclei are curiously shaped, often lobed or curved like a horse-shoe. In some the nucleus is represented by several small fragments, the sum total of which would not exceed a normal one. These are never found in the proper adenoid tissue of the gland. Whenever there is fibrous tissue between the covering and the gland the former has very few leucocytes.

The epithelium covering the follicular glands in the adult is permeated throughout in the same way.

From the examination at different ages and from different animals it appears that the wandering of the cells commences at the time of birth and continues during life if not interrupted by disease, and that it is a constant appearance, which can be verified on every mammal that has tonsils.

The possibility of these paths of egress serving as those of ingress for micro-organisms is suggested, but there is no proof given.

ON THE EXTENT AND CONNECTION OF THE LYMPHATIC TISSUE IN THE PHARYNX.

Bickel[2] has undertaken an investigation of the above subject in view of the relation in which the pathological processes known as angina and diphtheria stand to the tonsils; the points being to determine exactly how far adenoid tissue extends, and what structures are to be considered as tonsils. These are determined by a comparison of the literature of the subject, and by the examination of the pharyngeal region in twenty-four cases.

The first step is to find out in what form the lymphatic tissue presents itself in the pharynx. Of the chief importance is the tonsillar form. As characteristic of this is the tonsilla faucium, or palatina, of which the following are the structural peculiarities: —

(*a.*) Circumscribed form.

(*b.*) A thickly diffused infiltration of connective tissue with leucocytes within which lie small follicles.

(*c.*) Crypts, that is, blind pockets covered with epithelium dipping down into the lymphatic structure.

(*d.*) The direct contact of the gland cells with the epithelium, and increase of the surface from the furrows and clefts.

To these four points can be added: the presence of a large number of mucous glands, the ducts of which open at the bottom of the furrows. This is not absolutely necessary, but should not be left unnoticed.

According to this description only the tonsils of the pharynx deserve the name in addition to those of the fauces. On the other hand, those of the Eustachian tube as well as the follicular glands of the tongue are to be regarded as more superficially extended formations, having no marked aggregation of mucous glands. In other words, as transitional forms from a simple infiltration of adenoid tissue. Of this last three degrees are distinguished as occurring in the throat: —

(1.) One so marked that the lymph cells entirely hide the presence of the connective tissue.

[1] Virchow's Archiv, Bd. 97, S. 211.

[2] Virchow's Archiv, Bd. 97, S. 340.

(2.) Where the cells and tissue have about the same proportions.

(3.) Where the fibrous tissue exceeds the round cells.

From a comparison of the published descriptions of the pharyngeal region it can be stated that there is a perpendicular ring of lymphatically infiltrated mucous membrane, marked by scattered follicles. This begins above with the accumulation at the vault (pharynx tonsil); passes then to the opening of the Eustachian tube, where there is another marked aggregation of follicles; from there it turns downward along the posterior edge of the velum palatinum, around the posterior pillars of the fauces, to the tonsilla faucium, then obliquely across the back of the tongue, to return in a similar manner to its starting point. Professor Waldeyer has given to this the name of the "lymphatic ring of the pharynx."

As the result of the anatomical examination the following is apparent:—

The palate tonsils are present in the fœtal condition as well as during the first year simply as an infolding of the mucosa. A slight elevation appears first at the bottom of the depression thus formed, and gradually projects beyond the line of its opening. The edge of this lies as a sharply-defined narrow line on the base of the newly-formed tonsil. This line can often be made out in later life, but only as an incomplete circle. The others present an entirely different method of development.

On the base of the tongue strongly marked folds of the membrane are found in the fœtus. These disappear after birth, and in reverse relation to their retrogression are formed the follicular glands of the tongue.

A similar process is seen in the pharynx; here it looks as if the entire membrane of the throat would become a huge tonsil; fine longitudinal folds directed towards the base of the skull deepen, often almost imperceptibly, into the pharyngeal tonsil. Folds of a like nature mark the boundary of the tubal opening and the anterior and posterior surface of the soft palate.

In the course of the first twelve months of life these folds become obliterated, and there only remains the tonsils of the pharynx and tube. Microscopically those raised portions present a diffuse round cell infiltration, with numerous rounded aggregations.

From the above mentioned ring the adenoid tissue extends out into the floor of the mouth with varying strength and frequency. It reaches from the posterior surface of the soft palate into the nasal cavity in an amount varying with the individual, but can generally be recognized as far as the anterior ends of the inferior turbinated bones.

Also it reaches over the epiglottis down into the larynx as far as the glottis spuria.

The tendency to a greater or less susceptibility to acute infectious processes seems to be connected with the greater or less abundance of lymphatic tissue. The richer and more extended this is, the greater will be the possibility that the epithelial covering will be loosened by the continual passage of cells through it, and it is easy to imagine that by this means the deeper seated layers would be more exposed to injuries coming from without.

TUBERCULOSIS OF THE TONSILS.

Strassman [1] has examined twenty-one cases of tuberculosis in reference to the frequency of implication of these glands. It has seldom been observed according to the literature on the subject, although the position at the entrance of the respiratory and digestive apparatus would be extremely favorable for infection, and the structure is essentially the same as that of other parts of the lymphatic system which are notably affected. The author, however, found it in thirteen of his cases, but it was present almost exclusively in the form of minute tubercles. At times there were large numbers in a single section, at others only a few in many cuts. These bodies were rich in giant cells, while the bacilli were scattered. The adjacent tissue was scarcely affected.

With the eye alone it was only with difficulty that their presence could be detected, and they were found under the most varying condition of the gland, some normal, some atrophied, some hypertrophied, with or without concretions.

The question naturally arises, are these to be regarded as of primary origin, or are they secondary, due to infection with sputa, etc. From the results of experiment of inoculation by feeding, Baumgarten was inclined to the view contained in the first half of the question. The author, on the other hand, from an analysis of his cases, thinks that it must be an accompaniment of tuberculosis of the lungs, and that there is no evidence in support of a primary affection of the tonsils and a subsequent absorption of poison from them. Clinical importance is hardly to be ascribed to it.

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

NOVEMBER 10, 1884. The President, DR. CHARLES D. HOMANS in the chair.

PERIOSTEAL SARCOMA OF THE FEMUR.

DR. E. H. BRADFORD showed the specimen and gave the history. The first symptom was a small swelling of the upper thigh in August last. This gradually increased until within the last two weeks, when the tumor has grown rapidly. Last week aspiration removed blood, in consequence of which he amputated at the hip-joint. In amputating Dr. Bradford first excised the head of the femur, then amputated the femur at the junction of the middle and upper thirds, using the Esmarch rubber tube to control the hæmorrhage. After all vessels were tied and bleeding stopped the rest of the femur and the remainder of the tumor were dissected out. Hardly any blood was lost, and to-day, the fourth after the operation, the patient is in good condition.

PREVALENCE OF SCABIES.

DR. F. B. GREENOUGH asked if members of the Society had seen any great increase in scabies. The disease has not been common here for some time until of late, but recently he had seen a great many cases. There were six new ones at the Boston Dispensary to-day. He had traced one nest of thirteen or fourteen comparatively well-to-do people to others bringing the disease from Gloucester, where it is said to prevail among Portuguese fishermen. Other men engaged in dispensary work had seen an increase.

Dr. J. C. White stated that he had observed the same increase in the prevalence of scabies in Boston and vicinity during the last year, and was unable to account for it inasmuch as immigration, upon which we depend for our supply of the disease, had not been especially active during this period. He had seen several marked fluctuations in its occurrence in the last twenty-five years. Before the War of the Rebellion it was so little seen as not to be recognized by practitioners, and during the war it was regarded, in the armies, as an unusual form of the affection, and extended from them over the whole country. Later it was imported to a large extent by European immigrants during prosperous times, but with business depression subsided, and was seldom seen outside of returned cattle drovers from England until this recent revival.

UNUSUAL CASE.

Dr. W. C. B. Fifield reported the case. A gentleman left his office well in the afternoon, in the middle of June. Was attacked suddenly in the street with profuse perspiration, and became so sick that a lady gave him her seat in a horse car. He was, however, able to walk a quarter of a mile to his home in the suburbs, and to eat supper, feeling generally improved. The next day he apparently had acute dysentery, losing an unusual amount of blood. He had at that time grave mitral disease. Pulse rapid, and temperature 103° F. to 104° F. Treatment consisted of Epsom salts and opiates. In ten days dysentery disappeared, and the pulse and temperature fell. This gain was quickly succeeded by rheumatic iritis, first of the left and then of the right eye, to be followed in its turn by acute rheumatism of most of the joints and tenderness of the liver, with vomiting, which vomiting was relieved by a blister over the liver. Rheumatic remedies had no effect, nor had opiates unless given subcutaneously. As the joints recovered and the temperature fell, a profuse diarrhœa set in, the dejections resembling the rice water of cholera, and as this diarrhœa ended articular rheumatism returned. There was a dejection of pure pus, after which, as the articular symptoms abated, the eyes were again attacked in succession by iritis; then followed another articular rheumatism, and the last symptom was a third iritis of the left eye.

Aside from opiates the treatment which was of service was peptonized milk, and for the eyes atropia. During the third attack of iritis of the left eye, atropia in the strength of five grains to the ounce, was used persistently before it dilated the pupil.

To a question by Dr. Greenough Dr. Fifield answered that there was no hereditary history of rheumatism, and to one by Dr. Minot, that the heart remains as before.

HYDROCHLORATE OF COCAINE IN GENITO-URINARY, EYE, AND THROAT SURGERY.

Dr. A. T. Cabot reported several observations upon the anæsthetic properties of hydrochlorate of cocaine, showing its power of annulling sensation upon the mucous membrane of the urethra, glans penis, and prepuce: —

Observation 1. An elderly man with congenital adhesion of the prepuce over the posterior portion of the glans; suffering also from balanitis, which rendered the parts extremely sensitive, presented himself for treatment. A four per cent. cocaine solution was applied with a camel's hair brush; three applications being made within ten minutes; at the end of which time the prepuce was dissected off from the glans without causing the patient any pain. Towards the end of the operation a slight sensitiveness showed itself, but was almost instantly annulled by a reapplication of the drug.

Observation 2. The same patient had a stricture of large calibre requiring the passage of a sound. The meatus and mucous membrane just within it were extremely sensitive, as was tested with an instrument.

The cocaine was applied about the orifice and as far within the urethra as it could be carried on a camel's hair brush. Fifteen minutes later a large sound was passed without any uncomfortable sensation, until it reached the deeper portion of the canal.

Observation 3. A young man, with narrow meatus, who was extremely nervous and anxious to take ether rather than suffer any pain, had his meatus slit thoroughly to double its natural size without a sensation, the cocaine having been applied three times in the previous ten minutes.

Observation 4. A small abscess of the scrotum was painted over with a four per cent. solution of cocaine, three times in ten minutes, and at the end of twelve minutes it was incised. This caused considerable pain, although it seemed somewhat less than would have been expected had the cocaine not been applied.

Experiments are as yet wanting to show whether healthy skin is more readily affected than skin infiltrated with inflammatory products, and whether a solution of the drug strong enough to render the horny skin insensible can be safely employed.

It is worthy of note that in the first case reported, the application, when made to the raw surface of the wound, was followed almost instantly by anæsthesia.

Dr. C. H. Williams spoke of a case reported by Dr. Polk as showing clearly the anæsthetic effect of cocaine, for here the operation was prolonged until the effect of the drug began to pass off and pain was felt, but a fresh application of cocaine again produced anæsthesia, and the operation was completed without discomfort.

When applied to any mucous membrane, a decided effect of numbing is obtained, but on the skin no certain results have been got as yet.

Mr. Theodore Metcalf states that the best coca leaves come from Peru. Many are also shipped from Brazil, but the supply of cocaine is likely to be quite limited for some time, as only from one to two grains are obtained from a pound of leaves.

Dr. H. W. Williams reported the successful use of cocaine in two operations for cataract in the forenoon of the day of meeting. Only a single application of two drops of a two per cent. solution was made to each eye. At the end of five minutes the corneæ, which had been previously tested and found to be sensitive, had lost their sensibility, and appeared to have no consciousness when touched. No fixation forceps were used, the patient turning and keeping the eyeballs in the required position. The corneal incisions were made and the cataracts extracted with great facility and without any unsteadiness or any manifestation of pain on the part of the patient.

Dr. F. I. Knight said that he had tried the drug

as a local anæsthetic in operating on two cases of papilloma of the larynx. The preparation used was the only one obtainable at present in this market — a muriate made from the alkaloid by the addition of muriatic acid.

Dr. Knight at first sprayed the larynx with a two per cent. solution without much effect. On a subsequent day he applied the same solution to the larynx with a camel's hair brush. In one case the anæsthetic effect was marked, and the remaining papillomatous tissue removed with ease. In the second case, although the patient spoke of the "numb feeling" in his throat, there was not sufficient diminution of sensation to facilitate the operation. On another day a four per cent. solution was applied to the larynx of this patient with the brush, but with little effect.

The most marked effect on the throat which Dr. Knight had seen was on the pharynx of a phthisical subject, which had been very irritable, as is frequently the case in such patients. The pharynx was brushed over with a two per cent. solution, and almost immediately the patient complained of a queer feeling in her throat, and sensation was so much reduced that he could drum on the pharynx with the laryngeal mirror without exciting the least reflex action, in fact the patient said she did not feel it.

Dr. Knight said he felt confident that in this drug laryngologists would have a great aid in operative procedures, but that we had everything to learn in regard to the strength of the solution to be employed and the best manner to apply it.

DR. E. H. BRADFORD read a paper on

CASES OF LITTLE'S DISEASE,

which is reserved for publication.

DR. J. J. PUTNAM asked if any cases had been acute.

DR. BRADFORD answered that one of his cases was thought by the parents to be acute, but that on cross-examination it seems very questionable. The statement is often made that an attack came on after acute sickness, but on inquiring it is found that the patient did not walk before.

DR. J. J. PUTNAM said that he was unable to throw any light upon the pathology of the interesting disease spoken of by Dr. Bradford. He was inclined to think that the seat of the lesion might vary within certain limits, and yet the outward features of the disease — due, namely, to a spasmodic influence probably brought to bear on all the muscles, but permitting a predominant action on the part of the strongest or most automatic — remain the same.

Perhaps in some cases there is no gross lesion at all.

Dr. Putnam had recently made the post-mortem examination of a boy who had suffered for five years from a bilateral mobile spasm, with impairment of the intelligence, and had been able to detect no lesion whatever with the naked eye.

DR. CABOT mentioned cases in which the adductors acted to make the patients knock-kneed and in which the legs were tied apart in bed for many days, only to return to the old position in a few minutes. In these cases cutting the adductors has enabled the flat-footed patients to walk with a crutch one foot at a time.

DR. BRADFORD remarked that he had not himself seen cases so severe, but he did not see any reason why tenotomy or myotomy should not be done.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M. D., SECRETARY.

OCTOBER 11, 1884. The President, DR. C. ELLERY STEDMAN, in the chair.

DR. WELLINGTON read

A SUMMARY OF SIX HUNDRED CONSECUTIVE CASES OF MIDWIFERY.[1]

DR. REYNOLDS said that the Society owed its warm thanks to Dr. Wellington for his valuable and interesting report. The very small number of instances in which forceps were needed, once only in thirty-three cases, was worthy of notice; and this especially in connection with the extremely low rate of mortality — half of one per cent. It was instructive to observe a similarly low rate of death in the admirable report of the Dublin Rotunda, just laid before the profession by Dr. Macan. Equally good results with those recorded in Dublin had of late been obtained also in other places.

DR. DRIVER, present by invitation, observed that he used forceps in ten per cent. of his cases; but the number of cases in which he performed version was small, as he believed that as a rule the forceps operation was safer.

DR. REYNOLDS said: In reading the statement, now commonly made, of the very frequent employment of forceps, one cannot help wondering whether this instrument is not often used merely that one may promptly end a tiresome and difficult process. "Delay" in labor, as justification for operative interference, should bear a precise and definite meaning. Mere slowness, the general condition of mother and child remaining excellent, and steady progress, however moderate, being made, is not in this sense "delay." In this relation, the unwarrantable prescription of anæsthesia, which is becoming the habit of not a few accoucheurs in this vicinity, is to be greatly regretted; for hydrate of chloral, an excellent resource during the period of dilatation, is of no value in the expulsive stage. This abandonment of ether is excused, by asserting that anæsthesia delays the progress of labor, and farther that it must, if it lessens suffering, diminish at the same time uterine contraction and so prepare the way for flooding. Now it is as clear a canon in trying to relieve the suffering of childbirth as it is in treating intestinal colic, that the use of every remedy, opium, chloral, or anæsthetics, is conditioned utterly upon the presence of pain, upon its severity and its persistence. If there be but little pain, resort to any one of them is wholly unjustifiable. If under the employment of either of them the process of labor is arrested, the indication for continuing the agent ceases. It is true that in a small minority of cases ether suspends uterine action and must be withdrawn; but these instances, few in number, are more than offset by that other minority, not infrequently women of powerful frame and strong muscular development, who, broken down by intense suffering and wholly unmanageable, are yet able, when under moderate anæsthesia, to give invaluable aid.

In reply to questions the speaker admitted that he frequently saw fit to make the administration of ether for a time nominal, that he might test the value of voluntary efforts; but said that he believed that he had not for a long time been obliged in any case to for-

[1] See page 509 of this number of the JOURNAL.

mally relinquish anæsthesia on the ground under consideration. It is to be understood that in these remarks reference is had exclusively to what may be called the judicious employment of ether in average cases: and by this is intended such an exhibition of it as will lessen suffering without arresting the progress of labor; withholding it wholly the moment that pain subsides; never abolishing consciousness, and seldom taking away the power of intelligible speech. In thus using it the mere duration of labor is no doubt in most cases increased; but by what right does an attendant grudge for this purpose an added hour or half hour, provided the patient, who has little or no knowledge of time, is in great measure freed by his treatment from that risk of exhaustion which comes from the continued endurance of suffering. Obstetricians cannot be too strongly warned that the risk of hæmorrhage in childbirth, following loss of uterine contraction, is due wholly, utterly, exclusively, to loss of nervous power; that to bring about such exhaustion prolonged endurance of pain is the one all-powerful factor, as the wise palliation of agony is the best of all expedients for preventing the danger.

In operative obstetrics deep surgical anæsthesia is often of priceless value. Thus used, this remedy has been of incalculable worth in saving life. Nay more, its employment bids fair to revolutionize the practice of difficult obstetrics. Etherization carried to this extent will of course bring subsequent risk: the effect of the remedy must then be carefully watched and every precaution observed. Yet here also the good that is achieved far outweighs the added danger. Patients worn out in advance by mental worry or by bodily fatigue and those exhausted by repeated and continuous childbearing bring indeed to labor conditions that after delivery favor uterine relaxation; but even in these cases, provided severe suffering be present, the hope of escape from peril is probably not lessened, but rather increased, by the judicious employment of ether. The criticism upon it is as unreasoning as that which forbids us to administer hypnotics and opiates in the delirium of typhoid, on the ground that opiates arrest the secretions and diminish appetite. What suitable opiate will ever equal the exhaustion of sleepless delirium in producing these very results? "I am sure," an eminent practitioner lately said, "that I saved two valuable lives by adding under those conditions to chloral, bromide, and opiates the inhalation of ether, without which last I could give no relief." Few obstetricians in the United States can base their judgments upon a clinical experience more extended than that of Dr. Fordyce Barker: other observers are encouraged to express their strong convictions by his outspoken declaration of last year, that while he rarely, if ever, conducts a labor of any importance without an anæsthetic, he could not recall during many years a patient under his care, in whose case there had been post-partum hæmorrhage. It is a satisfaction to put once more these expressions of opinion before this Society. Would that the words could be made more emphatic! No man has a right to habitually withhold in his lying-in hospital this inestimable form of relief, or in the case of private patients to insinuate the alleged peril of its use, unless he can show clear and unmistakable evidence that such danger exists; and the burden of proof should lie wholly on his side.

DR. RICHARDSON did not favor the use of ether in childbirth for two reasons: in the first place he thought that ether caused a diminution in the force and frequency of the pains, whereby the labor was prolonged and the child's life occasionally endangered; in the second place he was persuaded that the uterus did not contract so well post partum when ether had been given and that therefore there was more danger of hæmorrhage. He had seen in hospital practice several instances of post-partum hæmorrhage which he was led to ascribe to the ether which the patient had taken: he had never seen post-partum hæmorrhage in private practice. In the first stage of labor he used chloral hydrate to prevent unnecessary suffering; but in the second stage he believed in the timely use of forceps, both to save time and to prevent suffering. He never waited until the fœtal pulse began to flag or intermit; but when with a fully dilated os the labor did not make constant progress, he seldom waited more than two or three hours before completing the delivery with forceps. In private practice one is frequently called upon to use ether, and in such cases he would never hesitate to use it, but should always feel a certain amount of uneasiness with reference to both mother and child.

DR. SINCLAIR said that for twenty years it had been his firm belief that the use of ether not only predisposes the patient to post-partum hæmorrhage but prolongs the labor: he therefore very seldom used ether in private practice except at the close of the labor and in instrumental deliveries. He was in favor of the early use of forceps, especially when a flagging fœtal pulse indicated that the child's life was in danger.

DR. BOARDMAN said that of late years he had given ether in private practice, and thought it promoted the labor and relieved suffering. He used it only in the second stage and gave it sparingly. He had never seen post partum hæmorrhage either in hospital or private practice which could be attributed to the use of ether.

DR. ABBOT said that after such a protracted discussion he would merely mention a case in his own practice which he thought well illustrated the evil of too free administration of an anæsthetic in labor as well as delay in the use of forceps. The case occurred years ago, at the time when the use of ether in childbirth was a novelty. A lady engaged him to attend her in her first confinement on the express condition that he should give her ether, and as freely as she wanted it. At the time little was known about the judicious use of this agent in labor. According to agreement she was allowed to inhale it very freely. As time passed its use was somewhat suspended, as it seemed to check the progress of the child. It did not, however, restrain the efforts of the patient in expulsion, for these were so great as to cause extensive emphysema of the cellular tissue, which extended from the eyes down to the breasts, probably from a rupture at the bifurcation of the trachea. The labor progressed slowly, at the end of thirty hours the head being partly through the superior strait. At this time, the child being alive, it seemed advisable to apply forceps. At the period when the case occurred this instrument was an obstetrical bugbear. Students were warned not to use it, except in great extremity. An eminent obstetrician was called in consultation, who, after due consideration of the situation, advised longer delay, as the patient was in a fair condition and pains were still active. Yielding to the authority of age and experience the patient was allowed to go unaided for twenty-four hours longer, the child making slow progress. At the

end of that period, the head being pretty low down, forceps were applied by the gentleman who had been called in the day before, with the result of a not difficult delivery of a dead child, very large, probably weighing twelve pounds. Dr. Abbot had no doubt that the free use of ether in this case had greatly retarded the labor, and that the delay in the use of forceps was responsible for the death of the child. This with subsequent experience had taught him the wisdom of a judicious use of anæsthetics in labor, as well as the great value and harmlessness of a timely use of forceps. The emphysema occurred during the last stages of labor, and the amount of ether inhaled was probably over two quarts. The emphysema disappeared by the end of a week, and the patient made an uninterrupted convalescence.

DR. WELLINGTON said, in reply to a question, that he did not believe it was safe to attend lying-in women coincidently with cases of scarlatina and erysipelas.

DR. INGALLS stated that in 1860 he had the professional care of about one hundred and thirty cases of scarlatina during an epidemic which lasted a period of seven months: this was in Winchester. There were all grades of the disease. Obstetrical and any other practice that offered he attended to as at any other time: careful review of the history of the epidemic soon after its close and many times since permits the assurance of his not having been the medium of communicating the disease.

PHILADELPHIA CLINICAL SOCIETY.

G. BELTON MASSEY, M. D., RECORDING SECRETARY.

MEETING of October 24, 1884. DR. BEATES in the chair.

EXTRA-UTERINE PREGNANCY.

DR. MONTGOMERY reported A Case of Extra-Uterine Pregnancy, Rupture, Peritonitis, Recovery.[1]

Also, for DR. JAMES SIBBALD, A Case of Extra-Uterine Pregnancy Successfully Treated by Electricity.[2]

DR. JOHN B. ROBERTS coincided with Dr. Montgomery as to the advisability of performing laparotomy where the symptoms of rupture continued urgent,

DR. CLARA BARTON asked what form of electricity had been used.

DR. G. BELTON MASSEY: The question put by Dr. Barton is of no little importance, and the answer should depend on a clear conception of the work to be done in a given case. Electricity is called upon for two separate and distinct functions in extra-uterine pregnancy: to kill the fœtus and to produce its absorption. In the former case a somatic death of the germ contained in the tumor is desired; in the latter merely a molecular death or change. In this latter instance, where the death of the fœtus has occurred, and we merely wish to promote its absorption, together with any effused blood or other material, the indications are almost exactly similar to those of any other intra-abdominal tumor, the current with greatest electrolytic power — the galvanic — is to be preferred. On the other hand, if we wish to arrest the onward progress of life in the fœtal mass in the interest of the unfortunate mother, that current which will accomplish this object with least danger to the mother is to be preferred. This is undoubtedly the faradic current. Shock must be the quality of value here. It is simply a question of transmitting a sufficiency of shock through the abdominal walls of the mother to the more vital parts of the fœtus. If the ordinary faradic battery is not strong enough the gravity of these sad cases would even warrant the building of a weak dynamo for this special purpose. As to method of application: the external percutaneous passage of the current by moistened electrodes would seem to be the best. A vaginal electrode might be used, however, the principal endeavor being to send the current directly through the tumor. Drs. Thomas and Mundé have recently reported a number of cases to the American Gynecological Society where successful results had followed the use of electricity. To my mind, however, their remarks as reported lacked definiteness in this matter of the choice of current, and the exact object desired in the individual case. Dr. Thomas does not advise the use of electricity after the fifth month, but an operation instead. Possibly he anticipated difficulty in then producing death, but this could be overcome by increasing the strength of current in the manner I have indicated; even if an operation was afterwards performed the previous arrest of the placental circulation might be of value.

In response to inquiries from Drs. Hall and Roberts, Dr. Massey said that an insulated sound with free extremity would form an excellent vaginal electrode, but that the use of acupuncture needles was totally unnecessary.

DR. MONTGOMERY, in closing the discussion, said that he had applied one electrode in the vagina in contact with the uterus and the other over the hypogastrium. He thought acupuncture unnecessary, though it was formerly the practice to use this procedure, as it was liable to cause peritonitis from the liquor amnii escaping into the peritoneal cavity. There is but little difference in the use of either current. There were two reasons why electricity was unavailable after four and a half or five months. The liability to rupture was greatest in the early months, — before the third month. After that we may as well allow the case to go on to a later month, as an operation will be necessary any way. A large fœtus is more dangerous to the mother after loss of vitality, and cannot be allowed to remain. Although the woman had fallen in the case related he thought the fœtus was still living, and therefore advised the electricity with the direct purpose to kill. Subsequently the tumor became smaller. The fœtus and appendages become encapsulated in the abdominal cavities of the mothers in these cases. There is no advantage in destroying the fœtus prior to operation.

[2] See page 511 of this number of the JOURNAL.

— The proceeds, amounting to $22,000, of a fête held at the International Health Exhibition, were distributed October 10th among the hospitals and dispensaries of London.

— The City Council of Philadelphia have been soliciting medical opinions regarding the effect on public health of salting the tracks. They have got views of diametrically opposite character, and will have to decide for themselves.

FIRST ANNUAL MEETING OF THE NEW YORK STATE MEDICAL ASSOCIATION.

Held at the Murray Hill Hotel, New York, November 18, 19, and 20.

First Day — Morning Session.

The report of the Committee of Arrangements was made by Dr. J. W. S. Gouley, Chairman; after which was delivered the

ADDRESS BY THE PRESIDENT,

Henry D. Didama, of Syracuse. In it he warmly advocated the three years' graded course of medical education, and strongly urged that it should be adopted in the large schools in New York as a worthy example to be followed by the others throughout the State.

THE ADDRESS IN SURGERY

was given by Dr. E. M. Moore, of Rochester, who took Transfusion for his subject. He preferred natural blood to defibrinated blood, milk, or saline solutions, and had devised a simple apparatus by which the blood could be conveyed to the veins of the patient without danger of injecting air or having the blood coagulate, which he considered the great points to be avoided. It consisted of a narrow rubber sac, into which the blood of the donor was to be received, to the lower end of which was attached a canula and mandrel, by means of which the stream flowing into the patient's vein could be instantly arrested whenever desired. He believed that a transfusion should never occupy more than one minute at the outside, and that two ounces, or less, of blood was quite sufficient for most cases. In case a larger quantity seemed necessary, the operation was to be repeated without withdrawing the canula.

Congratulatory addresses were made by Dr. Wm. Detmold, President of the New York County Medical Association, Dr. Shoemaker, of the Pennsylvania State Medical Society, Dr. Clark, of the Vermont Medical Society, and Dr. Wylie, of the Connecticut Medical Society.

Dr. Gouley, Chairman, read the

REPORT OF THE COMMITTEE ON ORGANIZATION OF DISTRICT ASSOCIATIONS,

proposing a plan for five such branch associations in the various sections of the State, which should each hold one stated meeting each year, and the president of each of which should be the vice-president residing in that district. The plan was unanimously adopted, and a recess was then taken for the organization of the district associations.

Afternoon Session.

Dr. J. C. Hutchinson, of Brooklyn, read a paper on

TRANSFUSION,

in which he described an apparatus devised by himself, the principal feature of which was a graduated glass cylinder provided with a thermometer, and surrounded by a double rubber sac filled with hot water for maintaining the temperature at the required point. Into the bottom of the cylinder was secured a rubber tube, to the lower end of which was attached a canula, provided with a stopcock, to be inserted into the median basilic vein of the patient. The fluid he used was a saline solution, and he thought that from twelve to twenty ounces was required, which should not be allowed to flow at a faster rate than one ounce per minute. He believed that the benefit to be derived from transfusion was not so much of a nutritive character as the restoration of vital fluid to the circulation and the stimulation of the heart.

Dr. Alfred L. Carroll, of New Brighton, Staten Island, read a paper on the

DURATION OF CONTAGIOUSNESS AFTER ACUTE INFECTIOUS DISEASES.

This was a question which had never been definitely settled; but was one of great practical importance, especially as regards the time that children should be kept from school after recovering from such diseases. With a view to obtaining light on the subject he had addressed inquiries to a number of prominent medical teachers and practitioners throughout the State; but for the most part had found a very wide variance in their replies, and he trusted that the Fellows of the Association would endeavor to aid him in the further prosecution of the matter by communicating to him the results of their own experience.

Papers were then read by Dr. John S. Jamison, of Steuben County, on Chronic Intestinal Catarrh, and by Dr. E. R. Squibb, of King's County, on

THE MODERN PROGRESS OF MATERIA MEDICA.

Dr. Squibb thought that polypharmacy was much less in vogue now than formerly; fewer and more active agents, the power and definite action of which were known, being employed. The more concentrated forms of drugs, like fluid extracts, were used in preference to tinctures and syrups, and they were prescribed not in the fixed doses set down in the books, but according to the physiological and therapeutic effects noticed in each special case.

Dr. W. H. Robb, of Montgomery County, read a paper on

THE MANAGEMENT OF CRIMINAL ABORTION.

In the discussion which followed Dr. Ely Van de Warker said that he regarded the use of ergot for the relief of hæmorrhage in abortion at or before the third month as a waste of time, and that irregular contractions were often excited by it; an opinion which was concurred in by Dr. Moses H. White, of New Haven, who thought it not only useless, but harmful, at this period, as it not infrequently caused the retention of the ovum by the abnormal contraction of the organ which it excited.

Dr. Charles Buckley, of Monroe County, read a paper on

CHRONIC MERCURIAL POISONING.

In a case under his care very serious symptoms resembling those of arsenical poisoning were found to be due to mercury used in coloring the hard, red rubber plate of a set of false teeth worn by the patient. He had since also noted several other similar cases, though less severe in character.

Dr. R. H. Sabin, of Albany County, read a paper on

A CASE OF ACUTE LEAD POISONING RESULTING FATALLY.

The patient, apparently in good health, suddenly became unconscious and remained in this condition for thirty-two hours, when death ensued. No autopsy was permitted; but the immediate cause of death was supposed to be cerebral effusion. Other men occupied in the same work as the patient suffered from the ordinary symptoms of lead poisoning.

The following papers were read by title: The Therapeutics of Diphtheria, by Dr. J. W. Moore, of Albany County; Notes on Dislocation of the Hip, based upon 238 Cases Occurring in the State of New York, by Dr. Frederick Hyde, of Cortland County; and Intestinal Obstruction, by Dr. Avery Segur.

NIGHT SESSION.

DR. H. E. MITCHELL, of Rensselaer County, read a paper on

ERRORS OF REFRACTION: THE IMPORTANCE OF THEIR RECOGNITION AND CORRECTION IN EARLY LIFE.

On account of the rapidly increasing number of defective eyes in children he thought general practitioners should be on their guard, and do what they could to put a stop to it. By means of an ordinary set of test types and the optometer, a simple variety of which he exhibited, such difficulties could be readily detected.

DR. AUSTIN FLINT, of New York, read a paper on the

DIETETIC MANAGEMENT OF DYSPEPSIA.

In what he said he wished it to be understood that he regarded indigestion and dyspepsia as distinct affections. As a rule, the diet which was beneficial to the healthy individual was beneficial to the dyspeptic, and the guides for eating should be the appetite, the palate, and common sense. Dietetic idiosyncrasies were by no means as frequently met with as was generally supposed to be the case, and the old adage that what was one man's food was another man's poison had little truth in it. It was of prime importance that the dyspeptic should be disabused of the notion that he should observe strict rules in regard to the quantity, quality, and variety of his food, as well as to the time of eating; and nothing was so well adapted to prolong digestive trouble as the habit of introspection indulged in by so many dyspeptics.

DR. N. C. LYNDE read a paper on

DOUBLE SYNCHRONOUS AMPUTATIONS.

It was accompanied by a table which he had made from reports received from surgeons throughout the State. The cases were nearly one hundred in number, and nineteen twentieths of them were due to railroad injuries. In amputations of the upper extremities nearly all recovered, while in those of the lower extremities (thirty-four in number) half recovered. He urged immediate operation, as a rule.

Dr. Lynde also read a paper on

THE FUNCTIONS OF THE AURICLES,

in which he took the ground that the auricles acted merely as reservoirs and diverticula for the blood poured into the heart, and did not contract, as claimed in the books.

This opinion was vigorously opposed by Drs. Austin Flint, Jr. Austin Flint, Sr., Moore, and Ross. The latter stated that at the last meeting of the New York State Medical Society he had reported a case of rupture of the auricle, which he thought could not possibly have occurred except in the act of contraction.

DR. E. D. FERGUSON, of Rensselaer County, read a paper on

THE USE OF THE ASPIRATOR IN HYDROTHORAX,

in which he said that owing to the dangerous and even fatal results which he had seen produced by the aspirator by causing pyothorax, he now never resorted to it except when dyspnœa or other serious symptoms supervened. Dr. Bowdich had maintained that the aspiration should be continued until the patient complained of pain in the epigastrium or dyspnœa; but he thought that it was much better that it should be stopped before this point was reached, as the occurrence of these signs indicated a more or less grave condition already, and he would advise that more than a pint of fluid at the outside should never be withdrawn at one time. In the pelvic cavity much evil had resulted also from the too free use of the aspirator, and on the whole he thought that the instrument had perhaps been productive of more harm than good.

DR. THOMAS F. ROCHESTER, of Erie County, read a paper on

A NEW PROCEDURE IN PARACENTESIS THORACIS.

This was the introduction of the finger through the opening, and the separation with it of the ribs, when the latter were so close together that it was impossible to insert a drainage-tube. He had practiced it in three cases with marked success.

In the discussion of these two papers which followed, DR. FLINT said that there was no doubt a great deal of truth in what had been said, but he was hardly willing to go so far as the author of the paper, and DR. MOORE said he was disposed to agree with Dr. Ferguson in regard to the use of the aspirator in acute pleuritis, but that in empyema it was vastly safer and better than opening the pleural cavity; while DR. ROCHESTER, who said he had probably performed paracentesis thoracis oftener than any one in the country except Dr. Bowditch, thought that it was a waste of time to employ aspiration in empyema, and that the use of the drainage-tube was the only satisfactory method of treating it. DR. FIFIELD, of Boston, remarked that ten years ago Dieulafoy had insisted that only a certain quantity of fluid, not to be exceeded, was to be withdrawn, and that he believed Dr. Bowditch had some time ago resorted to the procedure described in Dr. Rochester's paper. With his last instrument Dieulafoy had provided a set of canulæ which could be left in situ in the chest walls, and such a contrivance he thought was better than the drainage-tube.

The following papers were read by title: Pyæmia and Death after the Operation for Convergent Squint, by Dr. J. J. A. Burke, of Monroe County; Relations of Habit to Disease, by Dr. C. M. Kittredge, of Dutchess County; Report of a Case of Nephro-Lithotomy for Calculous Pyelitis, by Dr. Wm. Watkyns Seymour, of Rensselaer County; and Report of a Case of Excision of the Rectum for Cancer, also by Dr. Seymour.

SECOND DAY. MORNING SESSION.

PROPOSED LIBRARY.

On motion of DR. GOULEY, resolutions were passed

providing for the establishment of a library for the Association in the city of New York and for a library fund.

DR. S. C. ALLEN read a paper on

A CASE OF DIARRHŒA FROM DISEASE OF THE PANCREAS.

The patient had for some time what Dr. Allen called "adipose diarrhœa," but greatly improved under treatment. He had also granular disease of the kidney, however, as indicated by the condition of the urine, and finally died of uræmia combined with senile debility.

THE ADDRESS ON OBSTETRICS AND GYNÆCOLOGY

was delivered by DR. T. GAILLARD THOMAS, of New York. In it he spoke of the great advance in the prevention and treatment of puerperal septicæmia which the obstetrician had been enabled to make through the discovery of the bacterial origin of disease, of the treatment of extra-uterine pregnancy by electricity and laparotomy, of the induction of premature labor in placenta previa and aggravated nephritis, of the usefulness of Tarnier's tractors (which he regarded as the only real improvement in the forceps since the days of Smellie and Levret), of the advantages of laparo-elytrotomy, and of Emmet's, Battey's, Hegar's, and Tait's operations, and of the drugs recently introduced into this department of practice, such as permanganate of potash, and the fluid extracts of ergot of corn, viscum album, and viburnum.

DR. DARWIN COLVIN, of Wayne County, read a paper on

VENESECTION IN THE CONVULSIONS OF PREGNANT AND PARTURIENT WOMEN,

in which he claimed from a large experience that this was better than any other treatment; citing instances in which he believed death would inevitably have resulted had not free bleeding been resorted to.

In the discussion which followed DR. MOORE said that he believed that bleeding was of service in suspending the convulsions until the cathartics, which were always given in connection with it, had time to act, and that it was the cathartics that really cured the patient by eliminating from the system the poison which gave rise to the convulsions. Anything that would temporarily suspend these, therefore, would be useful, and he thought that ether was better for this purpose than bleeding, chloroform, morphia, or any other agent. Its inhalation was to be freely and steadily kept up until either the uterus was emptied or the bowels well moved by a purgative.

DR. THAYER, of Brooklyn, said that Norwood's tincture of *veratrum viride*, in doses of a teaspoonful, would also fulfill very admirably the indication referred to by Dr. Moore.

DR. C. C. F. GAY, of Erie County, read a paper on

FRACTURE OF THE BASE OF THE ACETABULUM.

Uncomplicated cases always got well without any treatment except rest, and as the positive diagnosis was always difficult, if not impossible, he wished to warn the profession against the danger of too much manipulation. He presented a specimen of fracture in three directions and involving the *os innominatum*, and read a history of the case.

TUBAL PREGNANCY.

DR. J. G. ORTON, of Broome County, read a paper on A Case of Tubal Pregnancy, at Full Term, of Fourteen Years' Standing.

Nearly one hundred bones of the fœtus had been removed through an opening which appeared spontaneously in the rectum, about four inches above the anus, when the patient died from an attack of diarrhœa, which was epidemic at the time in the town where she resided. The bones and sac were exhibited.

DR. NATHAN BOZEMAN, of New York, read a paper on a Case of Tubal Pregnancy, considered in Relation to Rupture of the Tube; Diagnosis and Treatment.

Dr. Bozeman performed laparotomy in this case; but as it was not until more than a week after the rupture of the cyst (the physician in attendance having mistaken the diagnosis), the patient died thirty-three hours afterwards from exhaustion. He urged the use of electricity to destroy the fœtus before the rupture of the cyst, and, in the event of a rupture, the immediate resort to laparotomy to arrest the hæmorrhage in the abdominal cavity.

The following papers were read by title: The Practice of Medicine of Forty Years Ago with Comparative Position at Present, by Dr. B. L. Hovey, of Monroe County; Notes on Peat as a Surgical Dressing, by Dr. W. S. Tremaine, of Erie County; and A Case of Ovarian Cyst, with Operation, by Dr. T. M. Lloyd, of Kings County.

DR. C. S. BULL read a paper on

HYDROCHLORATE OF COCAINE IN OPHTHALMIC SURGERY.

He had used it with success in a large number of operations, and spoke successively of its effects upon the sensory nerves of the cornea and conjunctiva, upon the pupil, and upon accommodation. He considered it a great boon to the ophthalmic surgeon in relieving him from the thraldom of ether and chloroform.

DR. MITCHELL said that he had been equally pleased with the results obtained from its use, though for a considerable time past he had found bromide of ethyl an excellent substitute for ether and chloroform. It was much more prompt in its action, and he believed that for short operations at least it was perfectly safe.

NIGHT SESSION.

The following papers were read by title: Common Sense Versus Hypothetical Medication in Treating Chronic Diseases, by Dr. Jonathan Kneeland, of Onondaga County; Cerebral Epilepsy, by Dr. C. F. Macdonald, of Cayuga County.

DR. FREDERICK W. PUTNAM, of Broome County, read a paper on a Case of Dislocation of the First Phalanx of the Thumb Forwards. The author of the paper had been able to find but four cases of this dislocation on record.

(To be concluded.)

— Sir Spencer Wells has been urging the claims of cremation in England, where, among its active supporters, are to be counted the Earl of Shaftesbury, Sir Henry Thompson, Mr. Ernest Hart, several of the Bishops of the Established Church, and the City of London Commission of Sewers.

Medical and Surgical Journal.

THURSDAY, NOVEMBER 27, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

THE WISDOM AND CONSTITUTIONALITY OF STATE REGULATION OF THE PRACTICE OF MEDICINE.

ANY movement in a democratic country like our own, having for its object a State regulation of the practice of medicine, is generally met and opposed by a cry of interference with individual rights, class legislation, and other well-known demagogical formulæ. When, moreover, such a movement is supported by qualified medical practitioners, who best know the evils which prevail in the absence of restrictions upon medical practice, a suspicion immediately presents itself to the minds of a certain portion of their fellow-citizens — a suspicion which is sedulously cultivated by the quacks and pretenders — that a monopoly is being created, and that such men, however respectable in their daily walk of life, are seeking their own advantage rather than that of the public.

This being the case, as we have on several occasions had reason to assure ourselves, it was with particular pleasure that our attention was drawn to a very clear and cogent statement of the constitutionality and desirability of the regulation of medical practice by State Legislatures, emanating lately from a member of the legal profession, a judge of the Court of Appeals of West Virginia.

The Legislature of West Virginia passed a law in 1882, similar to that existing in Illinois, to regulate the practice of medicine. The execution of the law, as in Illinois, was intrusted to the State Board of Health, which, like the State Board of Illinois, seems to perform its duties under the law in an active, efficient, and discreet manner. The law provides, in brief, that all persons desiring to practice medicine in the State shall present themselves before the Board for examination and a license, except such as had practiced in the State continuously for ten years prior to the passage of the law, or such as are graduates of a "reputable" medical college in the school of medicine which they profess, who may, upon presenting their diplomas and satisfying the Board, also obtain a license. Under this law the Board brought an action two years ago against a quack and obtained judgment. The defendant did not take exception to the allegations proved against him, but appealed on the ground of the unconstitutionality of the law. Judge Green, who presided, with his colleagues, at the second trial, affirmed the constitutionality of the law in an opinion which covers at some length and with much clearness, as we have said, both the merits and the soundness of such legislation.

Whilst there can be no doubt, as his Honor thinks, that the Legislature of every State should permit the utmost freedom of action by each citizen consistent with the public welfare, and ought not by law to impose any restraint thereon which the paramount claims of the community do not demand, it, of course, does not follow that the Legislature cannot legitimately restrain the action or conduct of any individual or citizen by a general law applicable alike to all, when such restraint is imposed for the purpose of promoting the comfort, the health, or the prosperity of the community at large. Under these circumstances the Legislature of any of the States has a perfect right under its general police power to pass laws placing individuals under restraint in the exercise of any business, calling, or profession. This power has been constantly exercised by State Legislatures, and the courts have universally recognized such power and have held that acts of the State Legislatures passed in the exercise of this power were constitutional and valid. In a great variety of cases State Legislatures have required licenses to be granted before a citizen could engage in a certain business or in certain professions, when from the character of the business or profession the public was liable to be imposed upon, unless the individual citizen was placed under this and other restraints imposed on all alike who engaged in such business or profession. Thus, laws have been passed to license bakers and to regulate both the weight and price of bread, and to prohibit the baking of bread for sale by those not licensed. And such acts of the Legislature have been held valid and constitutional. In no State in the Union is a citizen permitted to engage in the selling of intoxicating liquors without being placed under restraint by legislative acts. These restraints vary much in different States, and in very many of them the person desiring to engage in such business has first to obtain a license from a specified body or person, and before obtaining such license has to establish his fitness to engage in such business by proving his moral character. The general right of the Legislature by statute to regulate the sale of intoxicating liquors, and to place persons engaged in this business under whatever restraint the Legislature deems necessary to protect the community from injury, either to its morals or health, by those engaged in this business, is universally recognized by the courts, and is so well understood that no decision need be referred to as recognizing this species of legislation as valid.

Other sorts of business have also been put under restraint and regulation, the general rule being that the Legislature may restrain any one in the exercise of his natural rights to engage in any business whenever the promotion of the public safety, health, or prosperity requires a restraint of any particular sort to be put upon any particular business. The principle involved in this regulation by law of various sorts of business has been also extended to various callings and professions. Thus the practice of law is a profession

which the Legislature of every State has deemed one which should be regulated by law, and those engaged in this profession put under restraints for the protection of the general public. The person proposing to practice law is everywhere required to obtain a license from some person or persons qualified to determine whether the applicant has the qualifications necessary to practice law. The constitutionality of such laws or even their propriety has never been questioned.

The authority of the Legislature to require any one engaging in the practice of law to obtain a license is recognized as a matter of course. Statutes requiring that any person who undertakes to practice law must first be examined by judges competent to determine whether he has the requisite qualifications are based upon the well-known fact that none but those who have been specially educated with reference to practicing law can do so without great injury to the community who must employ lawyers in their business, and who are necessarily incompetent, to a considerable extent, to judge of the qualifications of a lawyer, and are thus subject to be imposed upon by pretenders ignorant of their profession. To furnish the community some protection against such impostors the statute law in perhaps every State in the Union prohibits any one from practicing law till he has first been examined by a competent judge or by a competent body of men, and a certificate of his qualifications and a permission to practice law has been obtained. The same reasons would seem to equally require that no one should be allowed to practice medicine who has not been first examined by some competent person, or body of men, as to his qualification to practice medicine, and obtained permission to do so, for it is obvious that the doctor equally with the lawyer requires a special education to qualify him to practice, and that the community in the case of the doctor, at least as much as in the case of the lawyer, are incompetent to judge of his qualifications, and are liable to be imposed upon by impostors and quacks professing to practice medicine. Indeed, the liability to imposition on the community through quack doctors would, Judge Green thinks, be even greater than their liability to be imposed upon by pretenders in the practice of law, yet the Legislatures of many States have singularly neglected to protect the community against imposition on them by quack doctors, but have left the community to only such protection against them as was furnished by the common law, and by it physicians undertaking to practice their profession were held responsible not only for due care and diligence, but for that degree of skill and capacity which ordinarily belongs to those who practice medicine. But, as in the case of lawyers, many of our State Legislatures have by statute law afforded additional protection to the community against the humbuggery of quack doctors.

It was claimed by the defendant that the law regulating the practice of medicine in West Virginia violated an article of the State Constitution, which provides that "all men are by nature equally free and independent, and have certain inherent rights, of which, when they enter into a state of society, they cannot by any compact deprive or divest their posterity, namely, the enjoyment of life and liberty with the means of acquiring and possessing property, and of pursuing and obtaining happiness and safety." This claim was disposed of quite summarily, the judge expressing himself as follows: "Of course all men have a right to the means of acquiring property, but the means used must be lawful means. An individual cannot acquire property by stealth or robbery. In so doing he infringes on the rights of others, on their right under this very provision of our bill of rights to possess property. So he cannot have a right to acquire property by the practice of medicine if he has no qualifications to practice medicine, and if in his attempt to do so he destroys the health of others in violation of the law of the land. And therefore the Legislature has a right by law to declare that he shall not acquire property by the practice of medicine unless he possesses the requisite qualifications, and there can be thus given some assurance to the community that he will not destroy the health of others. For how can others enjoy their life as provided for by this section of our bill of rights if any quack has an absolute right to destroy life by his attempt to practice medicine. The Legislature, therefore, in declaring what shall be the qualifications of a person before he shall acquire property by practicing medicine does not violate this provision of our bill of rights."

We do not reproduce these portions of the arguments advanced and the opinions expressed in this decision because they will be new to our readers, but because they come from a non-medical source, and are couched in plain words suitable for plain people. Those of our colleagues who have long been convinced of their truth themselves may some time find them useful in their efforts to convince others. We are glad to congratulate the State Board of Health of West Virginia upon the sturdy support which it receives in the discharge of beneficent but disagreeable duties.

DR. CLEVENGER ON POLITICAL ABUSE OF THE INSANE.

AT a recent meeting of the Chicago Medical Society Dr. S. V. Clevenger, special pathologist to the Cook County Asylum, a few miles from Chicago, read a paper on the Political Abuse of the Insane. Stating that the European governments subsidize laboratories and salary eminent physicians, he contrasted with this fact the condition of things existing in the average American asylum, more especially those controlled by local trustees instead of by legislatures. There is, he continued, a wonderful uniformity in the degradation of American institutions for the insane; the same brutalities are rife in them; the employees are generally of the same class; the same intriguing, bickering, and general roguery occur, and all of the so-called physicians are nearly of the same stripe; the same air of secrecy is maintained in one as in the others. While he admitted that a majority of asylum

attendants were kind hearted, the pernicious influence of the brutes was too prominent to be overlooked. These brutes were mostly active workers in political campaigns, who felt entitled to the political spoils. The average official who appoints such men is often of the same stripe. When $200,000 or $300,000 are yearly appopriated for the maintenance of an asylum the chances for division are excellent, because the inmates do not know enough to complain, and any officer who is not corrupt is usually intimidated into silence. If he cannot be entangled in some scandal or some hold cannot be secured on him the gang often concocts a scheme out of whole cloth and uniformly swears to it. It is pure accident if a good physician succeeds in effecting an entrance to an asylum as an appointee. The charlatan who abides in saloons and is well acquainted with the "boss" or members of the gang stands the best chance for election to office. Such a person is usually of the bummer order, who delights in pistol shooting and threatenings, who prostitutes his position in all sorts of ways for the benefit of bad politicians, — this he said and more.

We have quoted these remarks at length because we believe the author to be entirely misinformed with regard to the "average American asylum." We wish also to protest against such misrepresentation. With such statements upon record we cannot wonder that there has been so much unfair criticism of our institutions in Europe, and that most English alienists come over here to be agreeably surprised at the superiority of our asylums, in many respects excelling their own. Our distinguished colleague Dr. Tuke is the latest to bear witness to the admirable character of all of our insane asylums [1] which he had seen.

In speaking of the Cook County Asylum, Dr. Clevenger says of the newly-appointed reform medical superintendent, Dr. J. G. Kiernan, that his first order to the attendants was to restrain no patient without an order from a physician. A great uproar followed. This was an unheard-of proceeding there, and much nonsense was talked over the new order. The next order was that the night watch should not issue medicines to the patients at their own will, but were to call up a physician. As much as ten gallons of sleeping potions were doled out per month in the most unskillful manner to all classes of noisy patients. Any death resulting from this was of course attributed to "exhaustion from insanity." Among the new arrangements which disgusted the gang most of all was that requiring employees to take off their hats in the wards and address the patients in a decent manner. . . . The patients are insufficiently fed and scantily clothed. They suffer for everything. The medicines are impure and often valueless, and upon investigation, without whitewash in it, many terrible things may be brought to light.

If Dr. Clevenger has generalized from this one asylum we can readily believe that he had good grounds for his severe criticisms. But having had a pretty large experience in inspecting American insane asylums, and far from wishing to extenuate their faults, we must say that the Cook County Asylum is unique for its bad management, so far as our knowledge goes. Nearly ten years ago we called the attention of the Chicago physicians to some gross abuses [2] in the treatment of the patients there, and they (the Chicago Medical Society, if we remember correctly) promptly had them corrected. The Chicago Citizens' Association has requested the Chicago Medical Society to appoint a number of physicians to act in conjunction with laymen of the Association in investigating the charges of mismanagement at the County Insane Asylum. Drs. C. G. Smith, E. Ingalls, C. G. Paoli, R. Tilley, and C. W. Earl were appointed by the chairman, the Citizens' Association to select three names of the five presented.

We have always been opposed to insane asylums governed by local authorities, of which there are not very many in this country, believing that all such institutions should be under State direction, and we regret exceedingly the action of our last Massachusetts Legislature in going back to them.

[1] We exclude, as we suppose Dr. Clevenger does, the British asylums of Canada.

QUARANTINE AS A SIEVE.

THE discovery of a man dying from yellow fever in a boarding-house on Spring Street, in New York, November 19th, is a sufficiently good illustration of the value of quarantine in *excluding* disease from a country. The sick man had been steward of a vessel which arrived the day before from Costa Rica. The vessel passed quarantine upon the assurance of the captain that there was no sickness on board. A similar occurrence was reported from New York not many months since.

A REMARKABLE LAPAROTOMY.

DR. W. T. BULL, visiting surgeon at the New York Hospital, performed, November 3d, a remarkable laparotomy, the result of which has thus far, November 22d, been strikingly successful. The patient was a male, the victim of accidental shooting with a 32 calibre revolver, the ball entering to the left of and just below the navel. There were no symptoms of perforation, and he was in good general condition twelve hours afterwards. The bullet wound was explored under ether and found to penetrate the abdominal cavity. Laparotomy was performed, sutures taken in seven intestinal perforations, and the ball removed from the wall of the sigmoid flexure.

Favorable progress has been made since without serious symptoms of any kind, complete recovery being only delayed by an extra-peritoneal abscess in the abdominal wall.

— It is said that Bellevue Medical College will hereafter issue its diplomas in English instead of in Latin as heretofore.

[2] See vol. xciii., p. 692.

MEDICAL NOTES.

— By the will of the late Mrs. L. J. Kowles the sum of $25,000 is bequeathed to the City Hospital, Worcester, Mass.

— *The North-Western Lancet*, published at St. Paul, Minn., has passed under the editorial charge of C. B. Witherle, M. D. (Harv.), formerly of this city. The magazine is to be enlarged and otherwise improved.

— An epidemic characterized by hysteric and choreic phenomena is described in *Lyon Medical* (October 5th, *et seq.*) remarkable for its extent among a rural and ignorant class of persons and of young age. It occurred in a town of Ardèche, and began with a girl of eleven who was frightened by hearing the particulars of the death of a young companion. There was marked hyperæsthesia, especially of the senses of touch, hearing, and sight, followed by spasmodic contractions of certain groups of muscles. She continued at her work (connected with silk weaving), and soon other children who at first had laughed at her contortions were similarly affected. Nine other girls and two boys in all became victims to this strange disorder. When all were at work in a common hall an attack of convulsions would come upon all at once as by an electric shock. A peculiarity of the case was that several of the girls had not yet menstruated; in these no ovarian tenderness could be detected. Isolation and hydrotherapeutics constituted the principal treatment, which was effective in stopping the epidemic.

— A young female in a Spanish town is reported in the *Deutsche Medizinal Zeitung* (16th October) as in a remarkable cataleptic condition. She is twenty years old, and for nine months has not opened her eyes. She has become completely deprived of sensation. Various mechanical means, such as pricking, burning, friction, etc., have been tried to rouse her, but in vain. The respiration is regular, somewhat slowed, as is also the heart beat. The face neither very pale nor red. Body and limbs are very emaciated, with normal temperature. The teeth are closely shut on one another. The eyelids can scarcely be opened enough to allow of seeing the sclerotic.

— A correspondent of the *Medical Record* has recently published a list of "Therapeutical Delusions" of a pretty sweeping character, among which many practitioners will recognize some of their own pet prescriptions. That journal says editorially: —

"We have carefully examined the 'delusions' set forth by our correspondent, and find that in the main they agree with the results of the more conservative clinicians and of pharmacological experiments." They are as follows: "It is a delusion that veratrum viride or aconite will abort croupous pneumonia or essentially modify its course; that chlorate of potash is of any use in catarrhal angina; that nitrate of potash is an anti-pyretic, anti-rheumatic, or (to any appreciable extent) a diuretic; that lime-water will dissolve a diphtheritic or croupous membrane; that nitrate of silver is of any value in epilepsy; that the excessive and continuous use of iron induces plethora with dizziness, flushings, and palpitations; that iron should be given in phthisis; that mercury is anti-plastic and anti-phlogistic; that arsenic has any value in diabetes; that iodide of potassium promotes absorption of serous exudations and of non-specific connective tissue in hyperplasia; that sulphur and sulphur in baths is of any value in rheumatism; that charcoal, when moist in the stomach and intestines, has any absorptive power, or is of any use in flatulence by virtue of that power; that dilute acids are 'cooling,' that is, lower temperature and lessen heart action in the non-febrile; that colchicum is beneficial in rheumatism; that drinking sulphuric acid prevents chronic lead-poisoning; that iodoform given internally is anything but a poor substitute for iodide of potassium; that croton-chloral has a specific effect on the fifth cranial nerve; that tannic acid (or the plants containing it) is of any value given internally for hæmorrhages, except, perhaps, those of the stomach and bowels, or that it is of any value as a gargle in chronic pharyngitis, or that it is an astringent to mucous surfaces or blood-vessels; that turpentine is a stimulant to the heart and nervous system; that musk is a nerve or heart stimulant (it belongs with turpentine to nerve depressants); that ox-gall is of the slightest therapeutical utility; that hydrocyanic acid in ordinary medicinal doses is either a local or general sedative (it is rather an irritant); that quinine in either large or small doses is a stomachic, except in convalescence from malarial attacks; that hydriodic acid has any specific effects other than those possessed by the iodides."

— The significance of "intermittent pulse" is treated of by Dr. B. W. Richardson in the *Asclepiad*, July, 1884. The author states that if it occur in infancy it is an important indication of the existence of serious nervous derangement. Occurring in young adults it has the same meaning, and tells the story of commencing failure of power. In five cases the author has known it to be the first physical indication of derangement of mind in which suicide was attempted. In persons advanced in life and in persons prematurely old intermittency is often the herald of symptoms of nervous failure. Persons in whom there is permanent intermittent action of the pulse pass through all acute diseases with less chance of recovery than others of similar age and like constitution who have no such failure. The author also states that he has often noticed the hereditary character of the phenomenon. With reference to treatment, there is no known specific method. Excitement should be avoided, and in cases where there are symptoms of cerebral congestion depletive measures are sound. Nothing relieves the intermittent action of the heart so rapidly as alcohol judiciously administered, and nothing clenches the affection more decisively than alcohol indiscriminately prescribed. All alcoholic fluids as beverages must be avoided, but if the case demand it then at bed-time half an ounce of pure alcohol in warm water will often act most effectively.

NEW YORK.

— At a meeting of the County Medical Association held November 17th, Dr. Charles A. Leale read a

paper entitled A Study of Asiatic Cholera during the Epidemic of 1866, in which he said the following formula had proved of service in his hands: —

℞ Morphiæ sulph. . . . . gr. i.
Tinct. cardamom comp. . . . . f 3 i.
Tinct. capsici . . . . . f 3 iij.
Spts. camphoræ . . . . . f 3 i. M.

Of this a teaspoonful was to be taken, in two ounces of water, every fifteen minutes until the symptoms were relieved or rendered tolerable. It was then to be given at longer intervals until the effects of the morphia were observed on the pupils. The medicine might be required for at least three days.

— The recent meeting of the State Association was a splendid success in every way, and it was especially noteworthy for the large number of gentlemen in attendance from distant parts of the State, as well as of delegates from other States. Among the latter were Dr. Fifield, of Boston, Drs. Clark and Upham, of Vermont, Drs. M. H. White and W. C. Wile, of Connecticut, Dr. Garnett, of Washington, and Drs. Gross, Atkinson, Shakespeare, Solis-Cohen, Keating, Packard, and Nancrede, of Philadelphia. Dr. Earle, of St. John, New Brunswick, was also among the guests.

— *New York Cancer Hospital.* By the will of the late Mrs. General Cullum, one of the founders of this hospital, the Halleck estate in San Francisco, estimated to be worth $100,000, is left to this institution. At the time of its organization Mrs. Cullum subscribed $50,000. It is this hospital to which Mr. John Jacob Astor gave $200,000 a few months ago. The buildings are in process of erection at Eighth Avenue and One Hundred and Fifth Street, opposite Central Park, and will be completed in about a year's time.

— *Abdominal Surgery in the General Hospitals.* The general surgeons are entering on this field of practice, and with marked success. Dr. Stimson has recently reported two successful cases of supra-vaginal hysterectomy from the Presbyterian Hospital. At St. Luke's Drs. Peters, Little, McBurney, and Bull have performed eight laparotomies for ovarian or uterine tumors, with but one death, and one vaginal extirpation of the uterus with recovery. At the New York Hospital within the past three months the services of Drs. Weir and W. T. Bull have furnished a series of two ovariotomies, one supra-vaginal hysterectomy, and three vaginal extirpations of the cancerous uterus without a death. With the exception of Dr. Stimson's cases, which were treated in the General Hospital wards, most of these patients were operated on and treated at least for a week or ten days in private rooms. At the Woman's Hospital the "tumor patients" are still put into cottages.

WASHINGTON.

— Dr. Hosmer A. Johnson, of Chicago, has resigned from the National Board of Health, and Mr. W. P. Dunwoody, formerly clerk of the Board, has been appointed in his place. Mr. Dunwoody has also been appointed secretary of the Board to succeed Colonel Waring, who has resigned that office. We understand the funds of the Board are completely exhausted.

— Dr. S. V. Bemiss, of New Orleans, a former member of the Board, died lately.

Miscellany.

ADJOURNED CONFERENCE OF STATE BOARDS OF HEALTH.

At the conclusion of the report on the Prevention of Epidemic Cholera in America, during the meeting of the National Conference of the State Boards of Health at St. Louis, Mo., on the 13th and 14th of last month, and after urging upon Congress in the strongest terms its duty to enact such legislation and to appropriate such funds early in its coming session as will prevent the importation of this disease to our shores, it was resolved that when this Conference adjourned it should be to meet in Washington, D. C., the second Wednesday in December next, and that the Secretary be directed to invite the attendance at that time of the quarantine officers and the health officers of the principal cities in the United States and Canada; and that all delegates to that meeting be prepared to report the sanitary status of their State or locality, and what steps have been taken to improve the same, and to prevent the introduction of disease.

In accordance with this resolve a meeting of the Conference will convene at the Ebbitt House at ten A. M. December 10th.

SEWAGE FARMING AT PULLMAN.

The Pullman sewage farm, which is the largest experiment of purification of sewage by filtration in this country, says the *Chicago Tribune*, is *apparently* a success, both as to the purification of sewage, quantity and quality of crops, and financial return. It is on the Calumet River, near Kensington, and the sewage from Pullman is conveyed to it through an immense iron pipe three miles in length. The sewage is distributed through surface drains, and is carried off clear and odorless by a system of under-drainage. It has been in operation two years with the following comparative result: —

	1883	1884
Cabbages, heads	120,000	200,000
Potatoes, bushels	7,958	6,400
Onions, bushels	1,000	3,500
Squash, tons	10	45
Turnips, bushels	100	500
Celery, dozen bunches	8,200	18,000

Full cars of produce have been shipped all over the United States to such places as Vicksburg, Miss., Pittsburg, Pa., New Orleans, La., Atlanta, Ga., Memphis, Tenn. In less than car load, produce has been shipped as far east as Hartford, Conn., and Preston, Mass., and south as far as Galveston, Tex.

Sauerkraut works have just been completed, and if the low price of cabbage continues a large quantity of the article will be manufactured. A dairy farm stocked

with Holsteins has been started. Undrained land sown in oats averaged twenty-two bushels to the acre this year. Hay to the amount of one hundred tons was cut. About forty men and boys are employed. Middle men are not allowed to handle the produce. The crop of this year is larger than that of last year, but prices are lower. The crop of 1883 paid eight per cent. on the investment.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 15, 1884.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2374: under five years of age, 837; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 514, consumption 360, lung diseases 303, diphtheria and croup 228, typhoid fever 76, diarrhœal diseases 64, scarlet fever 49, measles 31, whooping-cough 23, malarial fevers 20, cerebro-spinal meningitis 13, puerperal fever six. From *scarlet fever*, Philadelphia 11, Boston 10, New York eight, Chicago seven, St. Louis four, Cincinnati three, Providence two, Haverhill, Quincy, Chicopee, and Randolph one each. From *measles*, New York 15, Cincinnati six, Philadelphia, Chicago, and Fall River one each. From *whooping-cough*, New York eight, Boston four, Philadelphia and Baltimore three each, Chicago two, St. Louis, District of Columbia, and Haverhill one each. From *malarial fevers*. St. Louis nine, New York five, Baltimore three, Philadelphia, Chicago, and Nashville one each. From *cerebro-spinal meningitis*, New York and Chicago four each, Worcester two, Cincinnati, Providence, and Lowell one each. From *puerperal fever*, Chicago four, Providence and Charleston one each. From *erysipelas*, New York, Philadelphia, Chicago, and Lowell one each.

Two cases of small-pox were reported in St. Louis. Cases reported in Boston: scarlet fever 61, typhoid fever 32, diphtheria 20, and measles eight.

In 109 cities and towns of Massachusetts, with an estimated population of 1,379,064 (estimated population of the State 1,955,104), the total death-rate for the week was 18.01 against 22.66 and 17.72 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending November 1st, the death-rate was 20.6. Deaths reported 3464: infants under one year of age 902; acute diseases of the respiratory organs (London) 348, diarrhœa 84, fever 67, scarlet fever 66, measles 57, whooping-cough 50, diphtheria 31, small-pox (London 21, Birkenhead two, Hull one) 24. The death-rates ranged from 15.0 in Norwich to 28.8 in Preston; Birkenhead 17.2; Birmingham 21.1; Bradford 21.4; Leeds 21.0; Leicester 25.5; Liverpool 23.0; London 19.5; Manchester 23.9; Nottingham 16.5; Sheffield 21.0; Sunderland 20.8. In Edinburgh 18.8; Glasgow 26.8; Dublin 24.7.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM NOVEMBER 15, 1884, TO NOVEMBER 21, 1884.

COWDERY, S. G., captain and assistant surgeon. Granted leave of absence for one month. S. O. 237, Department of the East, November 17, 1884.

HAVARD, VALERY, captain and assistant surgeon. Granted leave of absence for four months, — permission to go beyond sea, — to take effect when his services can be dispensed with at his present station. S. O. 268, A. G. O., November 14, 1884.

PHILLIPS, JNO. L., first lieutenant and assistant surgeon. Assigned to duty at Fort Keogh, M. T. S. O. 134, Department of Dakota, November 5, 1884.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE U. S. NAVY FOR THE WEEK ENDING NOVEMBER 22, 1884.

AMES, HOWARD E., passed assistant surgeon. Detached from the Greely Relief Steamer Bear and assigned to special duty in New York. November 17, 1884.

BRIGHT, GEORGE A., surgeon. Detached from the Galena and placed on waiting orders. November 19, 1884.

CLEBORNE, C. J., medical inspector. To duty at Philadelphia, Pa., as member of Medical Examining Boards. November 21, 1884.

DU BOIS, F. L., surgeon. When detached from the Naval Examining Board, November 29th, is ordered to the Galena. November 20, 1884.

GREEN, EDWARD H., passed assistant surgeon. Detached from the Greely Relief Steamer Thetis and assigned to special duty in New York. November 17, 1884.

HALL, J. H., surgeon. Detached from Navy Yard, Mare Island, and assigned to duty at the Naval Hospital at that Yard. November 19, 1884.

HUGG, JOSEPH, surgeon. To the Minnesota as relief of Surgeon Woolverton. November 15, 1884.

MARTIN, WILLIAM, assistant surgeon. To special duty in connection with the New Orleans Exposition. November 19, 1884.

NASH, F. S., passed assistant surgeon. Detached from the Greely Relief Steamer Alert and assigned to special duty in New York. November 17, 1884.

SIMON, W. J., surgeon. To the Philadelphia Hospital for treatment. November 17, 1884.

WOOLVERTON, T., surgeon. Detached from the Galena and placed on waiting orders for sea service. November 15, 1884.

OBITUARY.

DR. SAMUEL AUGUSTUS FISK died at his residence in Northampton, of organic disease of the heart, on Sunday, November 16, 1884, at the age of sixty-three. He was born in Cambridge, Mass., graduated at Yale College in 1844, and received his degree of M. D. at the University of Pennsylvania in 1846, establishing himself at Northampton four years later. He was President of the Massachusetts Medical Society from 1870 to 1872.

Of few men could it more regretfully be said, "The place which knew him shall know him no more." His life was eminently not one of those to be measured by figures on a dial, but rather by all which he did and purposed, and by all the sterling influences of his character. The good he did will live after him.

During his term of active practice his kindly presence and acknowledged skill were the solace and reliance of his patients; while his energy, sagacity, and high sense of honor gave him influence, not only among his fellow townsmen and the physicians of his immediate neighborhood, but extending through the counties of Western Massachusetts.

Thus he lived, devoted to his family, loyal to his friends, faithful to his profession. The education of his nephew for the profession he loved was to him an object of the deepest interest.

As in all his social and professional relations, so as President of the Massachusetts Medical Society he was an example of dignity, courtesy, fidelity, and sound judgment; and his zeal for its interests and reputation continued during his life, through all the anxieties and infirmities of threatening disease, of which he knew himself to be the subject.

BOOKS AND PAMPHLETS RECEIVED. — A Practical Treatise on Massage. Its History, Mode of Application, and Effects, Indications and Contraindications, with Results in 1400 Cases. By Douglas Graham, M. D., Fellow of the Massachusetts Medical Society. New York: Wm. Wood & Co. 1884.

An Aid to Materia Medica. By Robert H. M. Dawbarn, M. D. New York: J. H. Vail & Co. 1884.

Diseases of the Nose. By Clinton Wagner, M. D., Professor of Diseases of Nose and Throat in the New York Post-Graduate Medical School, etc. New York: Bermingham & Co. 1884.

A Theoretical and Practical Treatise on Hæmorrhoidal Disease, Giving its History, Nature, Causes, Pathology, and Treatment. By William Bodenhamer, A. M., M. D. Illustrated. New York: Wm. Wood & Co. 1884.

A Practical Treatise on Diseases of the Ear, including a Sketch of Aural Anatomy and Physiology. By D. B. St. John Roosa, M. D., LL. D. Sixth Edition, Revised and Enlarged. New York: Wm. Wood & Co. 1885.

Some Notes on the Pathology of Intra-Nasal Inflammation. By John N. Mackenzie, M. D., of Baltimore. (Extracted from Medical News, October 4, 1884.)

Quiz Compends? No. 10. A Compend of Organic and Medical Chemistry, including Urinary Analysis and the Examination of Water and Food. By Henry Leffmann, M. D., D. D. S., Professor of Chemistry and Metallurgy in the Pennsylvania College of Dental Surgery, etc. Philadelphia: P. Blakiston, Son & Co. 1884.

Manual of Chemistry. A Guide to Lectures and Laboratory Work for Beginners in Chemistry. A Text-Book specially adapted for Students of Pharmacy and Medicine. By W. Simon, Ph. D., M. D., Professor of Chemistry and Toxicology in the College of Physicians and Surgeons, Baltimore, Md. With Sixteen Illustrations on Wood and seven Colored Plates, representing fifty-six Chemical Reactions. Philadelphia: Henry C. Lea's Son & Co.

Hair, Microscopically Examined and Medico-Legally Considered. By Wm. J. Lewis, A. M., M. D., F. R. M. S., Hartford, Conn. Read at the Annual Convention of the American Society of Microscopists, August, 1884. (Reprint from Proceedings of the Society.)

Address.

CONSERVATIVE PROGRESS.

FIRST ANNUAL ADDRESS TO THE NEW YORK STATE MEDICAL ASSOCIATION, DELIVERED IN NEW YORK, NOVEMBER 18, 1884.

BY HENRY D. DIDAMA, M. D., SYRACUSE, PRESIDENT.

THE advance of science is hindered not more by obstinacy than by fickleness.

The skepticism which uses an honest crucible is a blessing; the skepticism which wields a club, and smashes old things indiscriminately *because* they are ancient is a curse. Underneath its destructive malice is often a credulous and craven tenderness for anything which is new.

One face of Janus was emblematic of Memory, and looked benignly upon the past with its garnered treasures; the other represented Hope, and peered eagerly into the rich possibilities and promises of the future. These faces were not mutually inimical; they were complemental; they were unity in diversity.

In medicine, bigotry and laziness sometimes call themselves conservative; opposed to these are discontent and love of novelty, which may assume the label progress; but genuine progress and enlightened conservatism work harmoniously together to perfect medical science: the one patiently tests all things, the other holds fast that which is good.

In medicine much is worthy of conservation; not a little is still moot; research is very active and confident; vast fields await exploration. Your attention is invited to a few illustrations and suggestions.

In *Pathology* the predisposing causes of disease are fairly well known by long and careful observation: but in the dazzling field of the microscope they are apt to be forgotten.

Inheritance, acquired vices, insufficient or improper or excessive food and drink, vitiated air, deficient sunlight, exposures, indolence, overwork, worry, these are predisponents which act by so impairing the resisting power that attacking foes of feeble potency are able to gain an easy victory.

Many diseases, such as eruptive, contagious, and malarial fevers; pneumonia, consumption, erysipelas, septicæmia, pyæmia, and even suppuration are now quite generally regarded as the work of micro-organisms — the *contagium vivum*.

The doctrine of germs is essentially modern; although Harvey is thought to have had glimpses of its truth more than two hundred years ago. But Harvey never regarded germs as living particles, capable of prolific multiplication; he considered the emanations from a certain disease able — by what he called a seminal influence — to propagate the same disease in a healthy person.

The witty Jonathan Swift, in the early part of the last century, described a microscopic specialist whose enthusiasm is hardly eclipsed by the zeal of any modern observer. He had discovered worms in the flesh of certain diseased animals, and he published an account of his observations. His paper attracted some attention and received favorable comment. Inflated with flattery and vanity, the now famous discoverer continued to use his lens, and forthwith published the startling announcement that worms are the fountain and origin of all diseases.

In the present germ excitement — analogous to the gold fever of 1848 and the petroleum craze of later years — we are not to ignore other and well-established causes. We encourage the search for new *microzymes* — as we do prospecting for gold and oil; we watch intently each promising indication, but we prudently reserve our credence and wait for verifications of alleged discoveries, knowing that some observers have that keen vision pointed out in the couplet: —

> "Optics sharp it needs, I ween,
> To see what is not to be seen."

We not only braid fadeless chaplets for the modest brows of those who unearth a new *Bacillus*, whose pedigree can be established beyond question, but we bestow our admiration upon those ingenious philological microscopists who, if they cannot diagnosticate hereditary diseases by the physiognomy of the blood corpuscle, are yet able to invent some magnificent name for the minutest pest which infests the human organism.

We urge that investigation cannot be too extensive and thorough, but we counsel that there be no premature rushing into print with generalizations, lest the observations shall turn out illusory, lest alleged causes shall prove to be but unimportant coincidences.

The reward for patient work may be slow in coming, like the flour from the mills of the gods, but it will be of excellent quality at last.

If he is worthy of national gratitude who makes two blades of unnecessary grass grow where but one had a feeble struggle for existence before, how much more deserving of temporary immortality is he who establishes his claim to a new *cacozyme*, be it *bacillus* or *micrococcus* or *spirillum*, especially if he can tell us what to do with it.

The specific micro-organisms of tuberculosis and splenic fever and — perhaps — cholera have been differentiated; those of miasmatic diseases, seen as the *palmella* in Ohio by a genius of sharp optics, and as a micrococcus by Italian observers, remain to be verified. There should be little doubt of their existence, notwithstanding the incredulity recently expressed by an eminent writer who still pins his faith to the ancient notion that a poison is generated by decomposing vegetation. For while a living and developing organism will account for all the facts of origin, incubation, and behavior of miasmatic fevers, a dead poison is quite unsatisfactory and insufficient.

But the germs which cause scarlatina, measles, pertussis, etc., have thus far eluded search. It is still an undecided question whether croupous pneumonitis be a germ fever with a local expression.

The suggestions of our eminent friend and associate, who called attention to this point several years ago, are entitled to, and are receiving, consideration throughout the world. Continued observations are still needed to confirm or overthrow the proposition.

In *Therapeutics* conservative progress finds an ample field. To prevent, to guide to a favorable termination when prevention has been neglected, to alleviate when recovery is impossible, to delay the inevitable escape of the soul from its weary prison, — these are the important duties of the physician.

A thorough knowledge of the composition and structure of the body, and of the relation of parts, is indeed of great importance. The action of organs in health, and their perverted action in disease, rightly demand the most careful study.

The foes which boldly attack the citadel of life, and the occult influences which insidiously undermine and sap the vital forces, these may well engage our earnest attention.

The fascinating analysis of our secretions and excretions, of our food and medicines and poisons, deserves all the consideration which it receives.

The innumerable instruments of precision, which promise to substitute mathematical accuracy for vague guess, and which are too often used not to supplement but to supplant other and valuable methods of investigation, these, like the tribe of Abou Ben Adhem, will continue to increase, till they become multitudinous — if not perplexing — like the grasshoppers of the West; these rightfully challenge recognition and study, while with unappeasable appetite they devour our substance if we attempt to add them all to our Armamentarium.

But anatomy and histology, physiology, pathology and chemistry, ætiology, diagnosis and prognosis; the possession of all the scopes, all the graphs, and all the meters, and the familiar and dexterous use of them; all these, interesting as they may be to the scientist, important and indispensable as they may be as preliminaries, foundations, and aids to medical skill, all these are practically worthless except as they contribute to the relief of human suffering.

"The real physician," says Broussais, "is the one who cures; the observation which does not teach the art of healing is not that of a physician, it is that of a naturalist."

And paraphrasing Sacred Writ, it may be added: there remaineth therefore pathology, diagnosis, therapeutics, these three; but the greatest of these is therapeutics.

Therapeutics, then, — which includes all means to prevent and manage disease, — being the superstructure to which all medical ologies are but foundation stones and adornments; the very fruitage of the tree of life; the sole beneficent application of all medical science, its importance to humanity, and therefore to the physician, cannot be overestimated.

Efforts to elevate the standard of medical requirements are worthy of commendation. Owing to the fierce rivalry of schools and the facility with which incompetence secures its diploma, it has been deemed very important, by many reformers, to have the licensing power placed in the hands of an independent Board of Examiners.

Should such a Board be constituted, it may properly require a thorough preliminary training, it may be so comprehensive in its demands, and so vigorous in its examinations, that no one guilty of ignorance regarding the fundamental branches of medical and other cognate sciences shall be able to gain admission to the ranks of a noble profession.

But if, in these exalted demands and these exacting examinations, therapeutics be ignored or belittled; if therapeutics be not elevated to the highest position and regarded as the one thing needful, the very vital principle without which everything else is but dead and useless science, and with which alone the physician does all his skillful deeds of benevolence, then the ordeal to which the candidate is subjected is delusive and beggarly. It may even deserve reprobation. The object of a Board of Examiners should be to protect the community from the ravages of additional incompetency. Its action must of necessity be prospective. It cannot hope to uproot a professional ignorance, which, associated with length of years and engaging manners, has become popular and almost sacred. But it can determine the minimum amount of knowledge which must be possessed by every candidate who shall gain admission to the medical fraternity.

If its examinations shall be comprehensive and searching, and at the same time not so narrow and technical as to regard an error in orthography less excusable than a gross blunder in medical practice, it may accomplish its good purpose. But if it tithes rigorously the mint, anise, and cumin, and neglects the weightier matters of applied medical science, if it shows partiality, allowing Vitreus Ceruleus, who believes the radiance which filters through blue glass to be the only and omnipotent remedy for all diseases, and the gushing Aquarius, who dotes on and swears by magnetized spring water as a panacea, and the innocent Credulus, who puts all his faith in faith alone, and the oily and plausible Sinbad, who pretends to be under the guidance of disembodied spirits, if the Board allows these to shirk entirely the examination in therapeutics and materia medica to which plain, unpretending Medicus — who recognizes the importance of these sciences — is subjected, then when it puts these five on the same high level before the public, giving each the same indorsement and the same license, it inflicts a wrong on Medicus, places an unnecessary and useless burden on Ceruleus, Aquarius, Credulus, and Sinbad, and perpetrates a fraud on a confiding and misled community.

To serve the public wisely and well the Board should subject every applicant, whatever his callow crotchets or prejudices or intentions may be, to the same examination in every branch of medical science as understood by the vast majority of the profession. Possessing the learning requisite to pass this examination, and endowed with his credentials, the tyro should be at liberty to adopt and practice any special delusion or idiocy which his fancy may indicate or the credulity of the public make profitable. For as he can never entirely divest himself of his useful knowledge the community will have all the protection it is possible for an Examining Board to furnish.

Some of the general principles of Therapeutics are worthy of the most careful preservation. Many of the measures employed in preventing and stamping out various so-called zymotic diseases are fairly successful; and constant research is adding largely to their numbers and potency. The importance of iodine and mercury in certain diseases; the palliative and curative effect of opium in a variety of complaints; the efficacy of Peruvian bark in miasmatic affections; the desirability and possibility of preventing and subduing high temperatures in fevers and inflammations; the wonderful results secured by certain heart tonics; the neutralizing and eliminating measures which have shortened the term of rheumatism from six weeks to six days; the undiminished power for good of ferruginous preparations in suitable cases; the occasional utility and even saving power of the once abused and now as much maligned venesection: these are merely samples of therapeutic principles and practice, whose truth is attested by countless critical level-headed observers throughout the whole world.

New discoveries in etiology, pathology, and materia medica will modify our views and constantly increase our ability to overcome disease. They will show us when to interfere actively and when to watch and wait.

And while we hold fast to well-founded principles of treatment and to remedies whose adoption has been tried, we give a hearty welcome and testing to every new measure, to every new medicine, which has a satisfactory indorsement. We are hampered by no dogma; so that while we are not seduced by utopian theories, while we make no experiments with obvious and gross delusions, and while we set our faces like flint against fraudulent pretenses and practices, we carefully consider every promising suggestion, by whomsoever made, and we gladly adopt every useful discovery, and every tested new application of old principles and remedies.

(*To be concluded.*)

Original Articles.

SOME DISEASES WHICH MAY BE MERELY SYMPTOMS OF THE EFFECTS OF POISONING BY SEWER GAS.

BY F. GORDON MORRILL, M. D.

NOTWITHSTANDING the attention which bad drainage and defective plumbing with consequent evils have attracted of late years, I am quite sure that we are in the almost daily habit of overlooking the fact that certain diseases are often caused and prolonged by the unsuspected presence of sewer-gas poison. I believe that a considerable percentage of all cases of sore throat (including both forms which tonsillitis usually assumes), trouble of the digestive tract, neuralgia, rheumatism, pneumonia, gout, asthma, and even so-called "nervous prostration," is attributable to this cause; and I have named these affections in the order of frequency with which they have occurred under my personal observation when good proof of their causation or prolongation by the presence of sewer-gas has been obtained.

The cases which I give are merely outlined for the purpose of illustration (as their only claim to interest is based upon their ætiology), and are fair samples of a respectable number of each kind which I have seen during the past five years.

CASE I. Gastro-duodenal catarrh. A. B., aged six, had a very severe convulsion December 10, 1883, which proved to be a manifestation of the above-named disorder, the symptoms of which had been well-marked for a month preceding. Under a proper regimen of diet and medicinal treatment the case progressed favorably for a fortnight, when a relapse occurred, and the child seemed as far from recovery as ever. The peppermint test revealed trouble in the bath-room adjoining her chamber, which was promptly remedied and speedy recovery followed. A younger sister, who had suffered from nausea and diarrhœa during the forty-eight hours preceding the examination of the drainage, at once got better, and both children have remained perfectly well ever since.

CASE II. Diarrhœa of a watery character. C. D., aged fourteen, was suddenly seized with intense abdominal pain in April, 1879. Numerous watery discharges soon followed, and persisted in spite of energetic treatment until the third day, when the trouble ceased, only to return again in a grave form (for now blood was present in the discharges) twelve hours later. A break in the drain under the cellar floor was found and repaired, and the child at once recovered. This would read well if reported in full as a case of "winter cholera."

CASE III. E. F., aged fourteen, had been under the care of an eminent practitioner during the four months preceding my first visit. Her symptoms were weakness, progressive emaciation, and great distress after taking food, the cause of which neither physical examinations nor the condition of the urine revealed. The long continuance of her trouble, its mysterious nature, and the fact that previous treatment had obtained no better results, led me at once to have the drainage examined, strongly suspecting that something wrong would be discovered. The result justified my suspicions, for the waste pipe of the bowl in the adjoining bath-room was found untrapped and leading directly into the soil pipe (which was not continued up through the roof), and a bad break was discovered in the main drain. A slow but steadily progressive recovery followed the necessary repairs.

CASE IV. G. H., aged forty-two; mother a chronic consumptive; the lady herself of poor physique and worn out with family cares, had pneumonia, right apex, front, December 10, 1882, from which she very slowly recovered. January 20, 1883, harsh respiration still detected over seat of trouble. Progressed slowly but favorably until February 5th, when a sudden attack of watery diarrhœa, accompanied by pain and a great many discharges, reduced her greatly. This condition lasted in spite of all remedial measures for five days, when the defects of drainage which had been discovered meanwhile were remedied, and the diarrhœa ceased as quickly as it had begun. The patient's condition was such at one time as to excite grave fears, and I think a possibly fatal result was avoided by recognizing the cause of the trouble.

CASE V. Neuralgia. A young lady, aged twenty-three, who had been subject to paroxysms of intense pain in the hepatic region during the two winters preceding my visit, was seen by me for the first time November 28, 1883, on which occasion the paroxysm was severe enough to require the hypodermic injection of one half grain of morphia. A history of her trouble revealed the fact that while absent from the city during the summer months she never had pain, but that upon her return to town the paroxysms at once began, and towards midwinter occurred with great frequency. She had been treated homœopathically for a long time as a case of congestion of the liver. Examination of the plumbing revealed an absence of any trap under the set bowl — which in this case was placed near the patient's bed. This deficiency was supplied, and the pain has never returned.

I can recall a number of neuralgia in which sewer gas has played an important part, and mention this one merely on account of its somewhat rare location.

CASE VI. Tonsillitis. J. K., aged thirty-seven. Subject for years to inflammation of the tonsils (accompanied by enlargement, but no deposit of any kind), which would confine him to the bed. In 1880 he came under my care twice with this affection.

No trap under set bowl. The patient, who is an active business man, decided to prevent any possible further trouble from this source, so had the pipe cut and sealed up, and a large jar placed under the bowl to receive the flow off. Since that time he has not had a tonsillitis.

Cases of follicular tonsillitis are often attributable to

sewer-gas poison, and numerous instances illustrating this fact have come under my observation, with the details of which I will not trouble my readers, as I think most of us realize that both this trouble and the ordinary erythematous sore throat may be thus caused. Dr. Langmaid informs me that in cases of public singers sojourning at hotels he has on several occasions advised cutting and sealing the waste pipes of set bowls to hasten the cure or prevent the recurrence of throat troubles.

CASE VII. Rheumatism. L. M., aged forty-two, subject to very severe attacks of inflammatory rheumatism and also gout, the latter being hereditary. In the house which he lived in cerebro-spinal meningitis, pneumonia, scarlet fever, and nearly all the other ills which flesh is heir to held full sway during the two years following the introduction of modern conveniences into an old-fashioned family mansion. His wife, too, had two severe attacks of rheumatic fever during this period. Competent authorities pronounced the entire arrangement of plumbing and ventilation to be faulty in the extreme, and L. M. decided to seek another residence, which he speedily found. Results: In his wife's case no more rheumatism. In his own case neither rheumatism or gout for eighteen months, when an attack of the former followed long exposure on a marsh during a shooting trip in the West.

CASE VIII. Pneumonia. An aged lady, the grandmother of Case II., a monomaniac on the subject of warmth, who never ventured out-doors from November 1st to the middle of May, had an attack of acute pneumonia in April, 1879, after a winter passed under the protecting influences of furnace heat, open fires, window strips, and numerous shawls and wraps of all kinds. At the same time another member of the family had watery diarrhœa (Case II.) and I think both diseases may be fairly attributed to the same cause.

CASE IX. Asthma. A little girl, aged eight, had severe paroxysms of asthma in the winter of 1878. The patient lived in a house where numerous faults in drainage and plumbing were discovered. The family were in poor circumstances, and the terms of their lease were such as to render them responsible for all repairs, while their lack of means prevented their seeking another residence until the present lease expired. Up to the time of their removal (October, 1878) the child continued to suffer from asthma, but the attacks ceased immediately after changing her residence to a house where the sanitary arrangements were good.

CASE X. Nervous prostration. Mrs. X., a lady of rather flighty temperament, but who had enjoyed good health until within two years of her first coming under my observation, in December, 1881. During the period mentioned she had suffered from intense weakness and all sorts of anomalous complaints, in short, her condition seemed composed of equal parts of hysteria and debility, and her life had become a burden to her family as well as herself. She had been assiduously treated by a regular physician during the first eighteen months, and during the six months preceding my first visit had been trying the "faith cure," so called, which in her case seems to have consisted in hiring a female of unprepossessing exterior and exaggerated dignity of manner to stare at her steadily for an hour or two every day. I was summoned to advise regarding an acute rheumatic affection which had recently appeared. Her other symptoms, with the mysterious nature of which she was fully impressed, she preferred to have remain under the supervision of the exponent of the "faith cure." Salicylate of soda very soon relieved her rheumatism, and I ventured to suggest that it would be well to have the drainage inspected. To be brief, this was found to be decidedly bad, and the mason and plumber soon brought about the disappearance of the nervous prostration and the dismissal of the exponent of faith.

This case has led me to wonder whether oil of peppermint might not prove indirectly the means of relieving some few of the cases of neurasthenia, with the details of which our ears are constantly filled by sympathetic friends of the sufferers.

The point which I have tried to establish is one which is often hinted at but not pressed so strongly as I think it deserves to be. When we are called to a case of typhoid nor diphtheria we at once order an inspection of the drainage and plumbing, and are seldom disappointed in finding defects, but I am convinced that we ought also to do this in many other cases of diseases which are as yet merely suspected of being infectious, and in some to which no suspicion is attached. Sewer-gas poison seems to seek out the patient's weak spot, and often brings discredit upon the physician, whose inability to relieve his patient is due to his failure to appreciate its unlimited powers of mischief.

THE USE OF MANACA (FRANCISCEA UNIFLORA) IN THE TREATMENT OF ACUTE RHEUMATISM.

BY HERBERT C. ROGERS, M. D., BROOKLYN, N. Y.,
Adjunct Surgeon Long Island College Hospital.

MY attention was first called to manaca by a physician practicing in South America. I am in the habit of giving the fluid extract in ten to twenty drops, using the preparation made by Parke, Davis & Co., of Detroit, Michigan.

CASE I. March 3, 1883. Was called to see James D., aged twenty-one, a native of Ireland, car driver. He had enjoyed good health until three days ago, when he was suddenly seized with a severe chill followed by fever and sharp pains in his limbs. The next morning he was unable to walk. The left knee and ankle were swollen, red, and painful. The right knee had been affected, but got better before he sent for me. He perspires profusely. Suffers most from his pain at night. He complains much of headache. Tongue badly coated. Bowels constipated. Urine deeply colored and free from albumen; specific gravity 1030. Pulse 130. Temperature 104° F. He was ordered five grains of calomel and ten grains of compound jalap powder, also ten drops of fluid extract of manaca every three hours. The painful joints to be covered with cotton.

March 4th, eleven A. M. He has had but little sleep during the night. The right knee and ankle have become inflamed. He suffers a good deal from headache. Bowels have moved several times. Examination of his heart negative. Ordered ten drops of tincture of opium with the fluid extract manaca every three hours. The painful joints to be wrapped in cloths wet with liq. plumbi et opii. Temperature 104½° F. Pulse 130.

March 5th, 11.30 A. M. Patient passed a better night. Has been able to sleep three hours. Swelling

and pain less. Temperature 103½° F. Pulse 120. Headache better. Vomited once towards morning Bowels have moved three times during the last twenty-four hours. Examination of heart negative. Treatment continued.

March 6th, two P. M. Still improving. Temperature 103° F. Pulse 120. Stopped opium unless pain should become severe. The fluid extract of manaca increased to fifteen drops every three hours.

March 7th, ten A. M. Pain, heat, and swelling have disappeared from all the joints with the exceptions of the right knee and left elbow. Treatment as before. Temperature 101° F. Pulse 114.

March 8th. Temperature 100¾° F. Pulse 110. No change in condition since yesterday.

March 9th. Found patient sitting up. The inflammation has disappeared from elbow. He says he feels well, and wants to go out. Temperature 99⅗° F. Pulse 100. Is to take the manaca three times daily.

March 12th. Patient about the house. Says he feels as well as he ever felt in his life, and is anxious to go to work. All joints are in a healthy condition. Appetite good. Is to take the manaca for a few days longer. Careful examination of his heart fails to detect any abnormal murmur.

CASE II. March 22, 1883. Fannie C., aged twenty-one, born in England, single, a seamstress by occupation. She had been confined to her bed for two days. Complains of pain, attended by swelling and redness, in almost all her joints, particularly of the knee and wrist. She has not been able to sleep for two days. The pulse rapid, 120. Tongue thickly coated. Urine high colored, free from albumen. Temperature 103° F. Ordered ten drops of the fluid extract of manaca in water every three hours, and one fourth of a grain of sulphate of morphia at bed-time. The painful joints to be enveloped in cotton-wool. Ordered a milk diet.

March 23d, ten A. M. The patient feels about the same. Has been able to sleep a few hours during the night. Temperature 102⅘° F. Pulse 120. Treatment continued.

March 24th, 10.30 A. M. Patient complains of severe pain in the shoulders and hands. Other joints are a little better. Increased the fluid extract of manaca to fifteen drops every three hours, and to take one sixth of a grain of sulphate of morphia every two hours till pain is relieved. Careful examination of the heart fails to disclose any abnormal murmur. Temperature 102° F. Pulse 118.

March 25th. Slight improvement. Pain in the hands and shoulders not so bad. The morphia seems to affect her bowels. Temperature 102° F. Pulse 118.

March 26th. Condition about the same. Pain, swelling, and redness disappearing from the joints. Reduced the fluid extract of manaca to ten drops every four hours. Temperature 101¾° F. Pulse 100.

March 27th. Same as last note. Temperature 101¾° F. Pulse 100. Continued treatment.

March 28th. A distinct systolic murmur was heard at the base of the heart to-day. The pulse has increased in frequency, being 120. Temperature 101¾° F. Is to take twenty drops of the fluid extract of manaca every three hours.

March 29th. Examination of heart to-day reveals a very loud murmur at the base, completely masking the second sound, and heard under the clavicle. A few bronchial râles are heard over the anterior part of the chest. Temperature 100¾° F. Pulse 116.

March 31st. Symptoms continue about the same. A double murmur is still plainly audible. The pain in all the joints is much less. The fluid extract to be taken every four hours. Temperature 100° F. Pulse 100.

April 2d. The improvement still continues. Her appetite is increasing, and she sleeps better. Temperature 100° F. Pulse 100.

April 4th. Condition about the same as last note. Temperature 99° F. Pulse 90. Treatment continued, with ten drops of tincture of iron three times daily.

April 7th. The double murmur still continues, but not so loud. It is heard at the upper end of the sternum, below the clavicle, but faintly at the apex. Temperature 98° F. Pulse 90.

April 10th. The pain is gradually passing away. The murmur is very faint at this examination. To take five drops of the fluid extract of manaca three times daily.

April 14th. The murmur has entirely disappeared. The patient is up and about the house. As she is still anæmic is to take the tr. ferri for a few days longer.

CASE III. January 15, 1884. Samuel A., aged twenty-three, bar tender, born in Germany, married, always enjoyed good health until a few days ago, when his left knee began to pain him, and became swollen, red, and hot. By advice of some of his friends he rubbed the joint with kerosene oil, and wrapped it up with flannel.

January 16th, two A. M. Patient had a chill this morning followed by pain in the right knee and thigh, which are red and swollen. He cannot bear anything to touch them, and complains if any one walks across the floor, as he says it jars the bed and increases his suffering. Temperature 103° F. Pulse 124. Ordered fluid extract of manaca in doses of ten drops every three hours, and sufficient opium to ease the pain. His joints to be enveloped in cotton-wool.

January 17th. The inflammation has extended to the left thigh, both shoulders, and ankles. He is covered with a profuse, acid perspiration. Urine scanty, but free from albumen. Temperature 103½° F. Pulse 130. Increased the manaca to fifteen drops every three hours.

January 18th. Condition unchanged. Is obliged to take one and one half grains of opium to produce sleep. Increased the manaca to twenty-five drops every three hours.

January 19th. Condition about the same as last note.

January 22d. Mr. A. is feeling more comfortable. He slept better last night than he has done for over a week. The pain, heat, and redness have nearly disappeared from all the joints, with the exception of the left knee, which is still quite painful and moderately swollen. His appetite, which has been very poor for the last two weeks, is improving, and he begins to relish such food as he is allowed to take. This consists of Volentine's beef juice, milk, and Vichy water. Temperature 101° F. Pulse 116. Continued treatment, with the exception of the opium, which is to be omitted.

January 24th, nine P. M. Patient's condition about the same as last note. No abnormal heart murmur can be detected. Temperature 100⅕° F. Pulse 110.

January 27th. Found patient sitting up in bed The pain, swelling, heat, and redness have disappeared rom right knee, thighs, shoulders, and ankles. The left knee is somewhat swollen, and gives him pain

when moved or touched. Careful examination of heart and lungs negative. Temperature normal. Pulse 100. Manaca to be reduced to fifteen drops every three hours. Also ordered

℞ Ferri et quiniæ cit. . . . . gr. lxiv.
Tr. gentianæ co. . . . . q. s. ad ℥iv. M.
Sig. Teaspoonful after eating.

February 3d. Patient resumed his business this morning. The left knee is still a little swollen, but free from pain.

CASE IV. Patrick C., aged twenty-five, expressman, born in Ireland, married, came under observation April 3d. On the 1st of April the patient had a well-marked chill, with vomiting, headache, fever, and acute pain in left wrist, accompanied by heat, redness, and considerable swelling. He grew weak, lost his appetite, and felt unable to exert himself, but attended to his business until April 3d, when he sent for me. I saw him at eleven A. M. The inflammation had attacked the ankles, knees, and right shoulder. Urine scanty, high colored, free from albumen. Temperature 102° F. Pulse 118. No abnormal cardiac murmurs perceptible. Ordered milk diet and twenty drops of fluid extract manaca every three hours. The painful joints to be bathed with the following liniment: —

℞ Liq. plumbi subacetatis . . . . . ℥ij.
Tr. opii . . . . . ℥i.
Aquæ . . . . . q. s. ad Oi. M.
Sig. External use only.

April 4th, ten A. M. Condition about the same. Slept fairly well last night. Complains that the milk makes him sick. Ordered five grains of sodii bicarb. to each glass of milk. Treatment continued. Temperature 101° F. Pulse 120.

April 6th, eleven A. M. Pain in all the joints, with exception of the left wrist, has been considerably relieved. Appetite is improving. Temperature 100½° F. Pulse 110. Applied small blister (2×2) to left wrist.

April 7th and 8th. Condition same as last note.

April 10th. The swelling, redness, and pain in all the joints have greatly diminished. Careful examination of the heart to-day fails to detect any abnormal murmur. Temperature 100° F. Pulse 100.

April 16th. All acute inflammatory symptoms have disappeared. Only slight stiffness of the limbs remains. The patient is able to go about the house. Appetite fairly good. Ordered the fluid extract of manaca to be discontinued, and the following tonic to be taken: —

℞ Tinct. ferri chlorid., Syr. Zingiberis, Aquæ, ... āā ℥ij. M.
Sig. Teaspoonful in wineglass of water, after eating, through a glass tube.

REPORT ON DISEASES OF CHILDREN.

BY T. M. ROTCH, M. D.

SIMULATED DISEASES IN CHILDREN.[1]

DR. JULIUS EROSS, assistant in the hospital at Budapest, has written a long and interesting article on this subject, describing the bad influence which sympathetic parents have on this class of cases, also the results of healthy children being brought in contact with those suffering from various nervous disorders, such as chorea. Girls were found to carry out the rôle of pretended disease better than boys. The symptoms were of all kinds: deafness, blindness, headache, pains in the extremities or thorax, palpitation, dyspnœa, spasmodic cough, vomiting, weakness of joints: clonic contractions, paralysis, convulsions, and many others. Eröss states that the unmasking of the pretended symptoms was found to be the best way to cure the children, and he cites a number of cases which he had observed in the hospital during the last three years. The following are some of the more interesting of his cases: —

I. H. K., a girl twelve years of age, began on the 8th of February to have such an intense spasmodic cough that a physician had to be summoned. Examination of the organs of respiration showed them to be normal; the cough continued with short intervals for four days, when she was sent to the hospital and soon recovered.

II. N. N., a girl six years old, pretended to be totally blind in one eye. Her father stated that she had received a blow on the left eye, that inflammation had followed, and resulting blindness. The ophthalmoscope showed the eye to be normal. The right eye was closed with a bandage and the child told to walk towards the examining physician, Dr. Vidor, who by various manœuvres soon proved that the sight of the pretended blind eye was perfectly good.

III. J. S., a girl eleven years old, was reported by her mother to have had repeated attacks of vomiting for three years; the vomiting lasted for days, sometimes weeks, and would then cease for five or six days and begin again. The vomiting was without straining. The child always retained solid food, but even a few spoonfuls of soup, milk, coffee, or water were immediately rejected. The patient looked so well nourished, and her functions were so regular, that it was soon observed that she really did not vomit at all, but that the liquids were retained in the mouth and not swallowed. She was kept in bed and only allowed to have soup and milk, which she very soon decided to swallow and retain.

IV. J. D., a girl eleven years old, had for two weeks complained of pain in the stomach, and during the attacks pains also in the upper extremities; the hands would begin to tremble so that she let her work fall and the trembling would last for several minutes.

V. R. L., a girl thirteen years old, was reported to have had the following symptoms for two years: tonic and clonic spasms of the upper extremities, of the trunk, diaphragm, and abdominal muscles followed each other in quick succession; the rigidly extended arms presented the appearance of epilepsy; the muscles of the shoulders were in active motion, so that the shoulder-blades moved quickly backwards and forwards. The lower extremities remained quiescent. These movements continued until the child had been in bed for an hour, and even then the shoulders and arms would twitch for a minute at a time. Sleep brought complete quiet, but on the next day the contractions returned as before. The child's confidence having been obtained it was found that she could at will control part of the movements while the other muscles were in action, and finally she consented to control all the movements, though for a long time she found it impossible to keep her fingers quiet on account of the contractions having extended over the long period of two years.

GASTRIC SYMPTOMS CAUSED BY INFLAMMATION OF THE LARYNX.[1]

The pharyngitis which accompanies certain diseases of the stomach in children, notably gastric catarrh, has for a long time been recognized and properly classed as a gastric symptom, and on the other hand disease of the larynx or pharynx may extend to the stomach either by swallowing the secretion of catarrhal, ulcerative, or malignant inflammation, by reflex irritation, or in consequence of the constant desire to swallow causing a frequent clearing of the throat and forcible swallowing of a small quantity of mucus, accompanied each time by a little air which may be thus pumped into the stomach in a sufficient quantity to cause serious derangement. In connection with this class of cases Dr. E. Löri reports some severe gastric symptoms in children, produced by inflammation of the posterior wall of the larynx.

In one case, a boy eleven years old had suffered from persistent vomiting of everything he ate for about three weeks in spite of careful treatment, all food being vomited a few moments after it was swallowed. The boy was intelligent and complained of nothing but slight pain in the stomach. On examination the posterior wall of the larynx was found to be intensely congested and swollen, so that it projected like a half hazel-nut. On the right side of the swelling was a raised white point, which proved to be a fish bone five centimetres long. This was removed, and all symptoms of stomach trouble vanished. Another child, five years old, had complained for three weeks of pain in the larynx and stomach, and during the last two weeks had had frequent eructations occurring ten to twenty-four times a minute, and only partially ceasing in sleep. The appetite was poor and the child pale and thin. Examination showed the larynx to be normal except on the posterior wall, where there were two raised points of inflammation. Tannin was insufflated, and in two days all the symptoms were improved, and after repeating the insufflation daily for two weeks the case was entirely cured. The author reports several cases of the same kind to show that in children it is not extremely rare to find gastric symptoms arising from inflammatory disease of the posterior wall of the larynx.

SEPTIC PNEUMONIA.[2]

Dr. Oscar Silbermann reports his observations on eleven cases of the septic pneumonia of infants, which have come under his care. Ten of the mothers had well-marked puerperal fever, and six of them died. Five of the infants were taken sick on the first day, five on the second, and one on the fifth day. All died. Four had pneumonia alone; seven had pneumonia and pleurisy. Icterus was only observed in four cases.

The disease always began with tracheo-bronchitis and fever. Dullness was often not well marked, and the other organs, as a rule, were not attacked.

The introduction of the poison in these cases was, apparently, by aspiration of the infected amniotic fluid.

The pathological appearances found in these primary cases of septic pneumonia were catarrhal pneumonia, and the alveoli filled with white and red blood corpuscles and cast off epithelium, while the interalveolar connective tissue remained normal.

In contra-distinction to the conditions found in these primary cases Silbermann calls attention to the cases of secondary septic pneumonia where the infection, starting from the umbilicus, extends under the peritonæum along the vertebræ, and under the aorta to the mediastinum, and thence, beside the intercostal and bronchial arteries, to the interstitial tissue of the lung and to the pleura, the alveoli remaining free. In this secondary form of pneumonia the symptoms pointing towards the lung are much less prominent, being usually masked by those caused by an accompanying peritonitis and meningitis. The author mentions also an especial predisposition in the new-born for direct puerperal infection through the air-passages, found in the peculiarly active changes in the superficial epithelial cells of the air-passages, the tendency towards innervation of the pharynx, and thus aspiration of fluid into the trachea, while the weakness of the expiration hinders the expulsion of foreign bodies from the bronchi.

THE BROMIDES IN INFANTILE THERAPEUTICS.[3]

Dr. Jules Simon, in a clinical lecture on this subject, states that the physiological effect of bromide of potash is to diminish the reflex sensibility of the mucous membrane of the pharynx and fauces. Small doses stimulate the gastric mucous membrane and increase the appetite. Large doses irritate the stomach and may cause intense gastralgia. After being absorbed the bromide of potassium slows and regulates the heart's action, but though it is not so dangerous as digitalis it cannot be given indefinitely in cardiac affections. As soon as the effect is obtained its administration should be suspended, for the continued use of it enfeebles the muscular system and the genital organs.

The bromides are indicated in eclamptic manifestations and cerebral irritability. In epilepsy progressively increasing doses should be given for several days and then gradually diminished. It is necessary, however, to keep up its administration for a long time after the attacks have ceased, using it, for instance, for fifteen days in every month. The combination of the bromide with the iodide is especially indicated in epileptic attacks symptomatic of cerebral lesions. Bromide of potassium is also indicated in the cephalalgia and cardiac irritation of adolescence. In regard to the doses, the average amount to be given to infants less than one year old is three grains in two doses at the time of nursing. Over one year, six grains may be given in two doses with food, and always well diluted. Over two years, fifteen, thirty, or even forty grains may be given until a marked physiological effect is produced. In some cases very large doses are required; in others increasing doses for five or ten days, then decreasing until it is suspended altogether.

MODIFICATIONS OF TEMPERATURE BY INUNCTIONS.[4]

Fourcault having shown that the application of an impermeable varnish to the skin of an animal causes a lowered temperature, several physicians have attempted to make a practical application of this refrigerant effect in exanthematous diseases, using fatty matters, collodion, or traumatieine (gutta-percha) dissolved in alcohol.

Schlemann and a number of German physicians, after different trials, have found that fever seems mo-t

[1] Jahrb. für Kinderheilk., xxi. B., 1 und 2 Heft.

[4] Journ. de Méd. de Paris, March 8, 1884. Amer. Journ. Med. Sciences, July, 1884.

influenced by inunctions. Senator was the first to make experiments of a serious and practical nature on this subject, using the thermometer as a guide. The experiments showed that in the healthy subject the application of fatty matters or varnish caused insignificant modifications of the temperature, but that if fever was present they diminished the temperature to a greater or less extent. Dr. Cobrat, of Lyons, has experimented with lard, cerate, and vaseline in the different acute affections of children, and in every case he obtained an abatement of the general temperature of the body. The thermometer in the rectum often showed a diminution of $1\frac{4}{10}°$ F., sometimes more, but rarely so much as $3\frac{6}{10}°$ F. The maximum abatement was attained in these experiments in about one hour after the inunction, and in from two and a half to three hours the temperature had again risen, while another inunction at this time gave the same results. Dr. Cobrat's experiments were made on children of from one to two years of age. He had occasion also to use this method in the case of a child of three months, and on another thirteen days old. In these cases the abatement was considerable. Under the influence of vaseline the temperature fell $2\frac{8}{10}°$ F. and even $3\frac{6}{10}°$ F. This treatment has been conclusively demonstrated to be free from danger by Schlemann, who used inunctions on scarlet-fever patients for more than four weeks at a time.

SUPPRESSION OF URINE.[1]

Dr. Paxon reports an interesting case of a boy six years of age and exceedingly anæmic, to whom he was called on the 5th of January with the history of not having passed any urine for two days. The catheter was easily passed, but no urine was found in the bladder. This state of affairs continued until the 8th, when the child vomited, and began to have a sleepy appearance. At this time a somewhat fluctuating tumor, the size of a lemon, was discovered in the lumbar region, between the kidneys. Injections of pilocarpine were then given, and on the 9th the tumor disappeared, and the child passed with great difficulty 538 grammes of very dark urine. Two days later suppression for twenty-four hours again occurred, but on the pilocarpine injections again being renewed the secretion of urine became normal, and has since continued to be so.

HYPODERMIC INJECTIONS OF MORPHIA IN CONVULSIONS.[2]

Owing to the well-grounded reluctance of physicians to give subcutaneous injections of morphia to infants it is well to record the cases where such injections have been given in order that we may have some recognized data by which we can determine what is a safe dose at different ages; this is of especial importance in the treatment of those severe eclamptic attacks which at times resist the usual methods of dealing with them. Dr. Clark, of Oswego, New York, reports the case of a girl eighteen months old, who had been in almost unintermitted convulsions for two hours, various remedies producing no effect. The cause of the attack could not be ascertained, but was supposed to be of cerebral origin. One sixth of a grain of morphia sulphate was injected into the arm, and in about two minutes the convulsion ceased entirely, and after a quiet sleep of three or four hours the child awoke apparently well. Twenty-four hours later, after some evidence of the attack returning, the symptoms readily subsided to doses of Dover's powder, in moderate amount, the dose not being stated. In some days, however, the child was found to have her faculty of speech, which was considerably advanced, impaired; since then her appearance has been bright, and her power of speech is constantly improving. Clark believes from his experience that a child of from two to five years old will stand as much opium in proportion to the development at that age of the energies of the nervous system as an adult. He also states that he would unhesitatingly inject a thirty-second of a grain in persistent or recurrent convulsions and repeat in fifteen minutes if necessary. In connection with Clark's cases Dr. Hughson reports the case of a Negro boy, two years of age, who had been sick with a high fever for two days, and who had been in convulsions for an hour; the child was unable to swallow, and was rapidly sinking into a dying condition. A subcutaneous injection of a fifteenth of a grain of the sulphate of morphia was given, and in ten minutes he was quiet, and in twenty minutes asleep; the child had malarial fever. There was no return of the convulsions, and there was complete recovery from the malaria.

RÖTHELN.[3]

Dr. W. A. Edwards, having had an opportunity for observing one hundred and sixty-six cases of what he considered rötheln at the Philadelphia Hospital, presents the following conclusions in a paper on this subject: He places the stage of incubation at about ten days, or rather between ten and twelve days, and the prodromal stage, in which the temperature of thirty per cent. of the cases did not exceed 100° F., at three days. The eruption usually began on the face, and rapidly spread over the body and limbs; it was multiform in character, punctated, and at times macular, more or less confluent, and appearing in patches which were very irregular in outline and size, and the centres of which were much higher in color than any other part. In the eruptive stage the temperature rose from one to three degrees, being in proportion to the extent and severity of the eruption. The eruption lasted on an average five days, and was followed by a desquamation of furfuraceous scales. Sore throat was always present, and the cervical glands were enlarged. Slight albuminuria was present in thirty per cent. of the cases, and in nine cases the albumen was considerable, and was accompanied by dropsy, but no casts were detected. The chief points of differential diagnosis relied on by Dr. Edwards are the eruption appearing on the third day, first on the face, its rapid extension, its gradual shading off into the surrounding skin, its elevation, more particularly in the centre of the patch, which is also the brightest in color, and the point where desquamation first shows itself; also the laryngeal character of the cough and the continual presence of sore throat. He also notes in his cases as of diagnostic value that they never gave rise to or protected from measles or scarlatina. [These cases are reported in order to show that although there may be a disease rötheln *per se*, yet the reports of the symptoms of such disease as laid down by those who have observed it during epidemics vary so much that we are still at a loss to give an exact picture of the disease, as we can of measles and scarlet fever. T. M. R.]

ERYSIPELAS.[1]

Erysipelas in infancy, especially if it invades large surfaces, is such a serious disease that the following case is of interest from the fact that the child recovered. An infant ten months old was attacked with redness and swelling of the right labium. The whole vulva soon became greatly swollen and very tender; the disease then extended to the pubes and the abdomen, and invaded every part of the body and limbs, requiring about four days from its appearance at any part until the skin of that part assumed its normal color again. When the erysipelatous inflammation extended to the feet there was marked œdema. The neck and head were also invaded, the eyelids and lips being the last points of attack; even the palms of the hands and soles of the feet were affected. The duration of the attack from its commencement at the vulva to its disappearance at the eyes and mouth was fifteen days. Iron and quinine were given internally.

Hospital Practice and Clinical Memoranda.

COCAINE IN OPHTHALMIC SURGERY.

BY B. JOY JEFFRIES, M. D.

I HAVE been using cocaine for eye operations during the month of November past with a little different result from those some others report. From two to eight per cent. solutions were tried. I judge four per cent. will answer, if, of course, the drug is pure. We can, however, be assured of the effect before operating. The cases were cataract, strabismus, secondary capsule, superficial and deep foreign bodies in cornea and sclerotic, chalazoin, etc. The solution with acid smarts a little, not over thirty seconds, and so does the drug dissolved in hot distilled water. In *thirty more* I have always found the eye anæsthetic. I therefore do not understand the reports of gentlemen here and abroad of having to wait several minutes, etc. In one case of squint the pupil dilated as with atropine. Several drops have to be used for this operation, and hence the effect is probably more marked.

Anæsthesia can readily be kept up by the application of a drop every few minutes. In between twenty and thirty operations I have seen no ill effect to be attributed to the drug. In one third of these I should have used ether. The time and pain saved in the foreign-body cases were well worth saving. If the drug only allowed us to hold the lids apart *continuously* it would be most valuable. The cases of foreign bodies deep in the cornea or sclerotic would have required prolonged use of ether.

After the first incision in chalazoin the solution applied to the wound deadened the pain, but seemingly only as far as it reached. This was also the case in squint operation. Sensation was destroyed by a few drops (four per cent.) in the conjunctival wound. The eye speculum, of course, gives an unpleasant dragging sensation, but its presence is tolerated for several minutes, in fact, as long as the anæsthesia is kept up.

From one to ten drops have proved sufficient for the operations I have done. The expense is nothing compared with the relief from pain and, in children, the fright, etc. *Pulling* on the iris seems to cause pain, and one must be careful on this account. *Cutting* it when drawn out does not. Hence a caution as to Passarant's operation. Enucleation I have not yet done with the drug. I see no reason why we should not use a drop to quiet the eye so as to get a thorough inspection in adult or child.

Reports of Societies.

FIRST ANNUAL MEETING OF THE NEW YORK STATE MEDICAL ASSOCIATION.[2]

SECOND DAY. NIGHT SESSION.

DR. JOHN P. GRAY, of Utica, read a paper entitled

HINTS ON THE PREVENTION OF INSANITY.

Many of the cases of insanity which he met with at the State Asylum at Utica might have been prevented, he thought, if the patients had been properly treated at the first. It was at the very beginning of nervous trouble that such cases should be taken in hand, and he gave suggestions of the methods by which, with judicious dietetic, hygienic, medicinal, and moral treatment, insanity might be warded off in a large number of instances.

DR. STEPHEN SMITH, of New York, read a paper on

EXCISION OF THE KNEE IN PREFERENCE TO AMPUTATION IN CERTAIN DEFORMITIES OF THE LEG,

in which he said that excision was preferable because statistics showed that it was at the least fully as safe as amputation above or below the knee, and that it was a recognized fact that an anchylosed knee was more useful to the patient than any stump.

In the discussion which followed DR. S. W. GROSS, of Philadelphia, who was one of the delegates from the Pennsylvania State Medical Society, described an operation devised by his father for breaking up the adhesions and releasing the patella in bony anchylosis of the knee-joint, so that the limb could be extended until the heel came within one inch of the ground, which was found to be the best position for such patients. DR. MOORE thought that excellent results could be obtained with the osteoclast of M. Robin, of Lyons.

THE CURETTE.

DR. GEORGE T. HARRISON, of New York, read a paper on The Curette: Its Place and its Power in Uterine Therapeutics, in which he described the various conditions of the uterus in which the instrument was applicable and the best method of using it in appropriate cases. Careful preliminary treatment was often required, and it was sometimes necessary to dilate the os uteri with steel instruments; while anæsthesia was advisable in some cases. Antiseptic injections were always to be made, and the patient should be advised to keep her bed for a day or two after the application of the curette.

DR. FREDERICK S. DENNIS, of New York, read a paper on

THE RELATIONS BETWEEN TUBERCULOUS JOINT DISEASES AND GENERAL TUBERCULOSIS.

The tuberculous origin of a large number of cases of joint disease was, in his opinion, clearly established;

[2] Concluded from page 521.

the presence of the bacilli tuberculosis at the seat of disease affording the most positive proof of this. According to the best statistics, only one sixth of the cases of joint disease were attributable to traumatism, while one third of them were associated with scrofula. Scrofula, however, acted only by presenting a suitable soil for the development of tuberculosis. The latter always spread from local foci, and if the local disease could be removed early by operation or otherwise, the development of general tuberculosis might be prevented. He related a case in which he performed amputation for disease of the knee joint in which the presence of the bacilli tuberculosis was demonstrated by Prof. W. H. Welch, and in which the patient, although he recovered well from the operation, afterwards died of acute miliary tuberculosis; almost every organ in the body being the seat of tubercular deposit.

DR. GROSS, in an able address, during which he said that tuberculosis in its action in the system was precisely analogous to cancer, expressed himself in perfect accord with the views of the author of the paper.

DR. WM. T. LUSK, of New York, read a paper on

THE MANAGEMENT OF BREECH CASES IN WHICH THE LOWER EXTREMITIES ARE EXTENDED UPWARD PARALLEL TO THE BODY OF THE CHILD.

If instruments were required he preferred the forceps, especially with Tarnier's tractors, to any other. Next in his estimation stood the fillet, and then the blunt hook. If the child was believed to be dead the cephalotribe was the most useful instrument.

DR. THOMAS H. MANLEY, of New York, read a paper on

WOMEN AS MIDWIVES,

advocating the establishment in New York of training-schools for midwives.

THIRD DAY. MORNING SESSION.

CONGRATULATIONS TO MESSRS. CARNEGIE AND VANDERBILT.

DR. FLINT submitted resolutions, which were unanimously adopted, offering congratulations and thanks on behalf of the interests of science and of humanity, to Messrs. Andrew Carnegie and Wm. H. Vanderbilt for their recent munificent gifts to the cause of medical education.

ELECTION OF OFFICERS.

The following officers for the ensuing year, which were proposed by the Committee on Nominations, were unanimously elected: President, Dr. John P. Gray, of Utica; Vice-Presidents, Drs. W. H. Robb, of Montgomery County, J. G. Orton, of Binghamton, J. C. Green, of Buffalo, and J. C. Hutchinson, of Brooklyn. New members of the Council: 1st District, Dr. Wm. Gillis, of Franklin County; 2d District, Dr. R. C. McEwen, of Rensselaer County; 3d District, Dr. Frederick Hyde, of Cortland County; 4th District, Dr. Darwin Colvin, of Wayne County; 5th District, Dr. J. W. S. Gouley, of New York County. Dr. S. S. Purple was appointed member of the Council at large by the President-elect.

DR. AUSTIN FLINT, SR., of New York, delivered an

ADDRESS ON MEDICINAL AND NON-MEDICINAL THERAPEUTICS,

in which he urged that a common sense view of treatment should be taken; withholding drugs where the healing power of nature could accomplish the recovery of the patient better without their aid, and prescribing them judiciously where clear indications were presented for their use. In the course of his remarks he spoke at some length of the many useful properties of alcohol in disease, and also of the importance of moral influence upon the patient. A satisfactory work on mental therapeutics he thought was a desideratum in medical literature.

Resolutions of sympathy for Dr. L. A. Sayre in his long illness, proposed by DR. FLINT, were adopted, and the President-elect, DR. GRAY, who was introduced by the Chair, then made a brief address.

THIRD DAY. AFTERNOON SESSION.

DR. CASPAR GRISWOLD, of New York, read a paper on

FALSE ALBUMINURIA.

The substances found in the urine that were liable to give a precipitate resembling urine were, phosphates, mucus in such excess that a slight cloud would not be observed, uric acid, peptones, and resinous drugs, like copaiba. Having explained the methods of detecting these he spoke of cases in which albumen was present in the urine but did not come from the kidneys. It was then due to the presence of blood, pus, or prostatic or spermatic fluid.

Papers were read by Dr. Samuel W. Smith, of New York, on The Early Use of the Knife in Nævus of the Cavernous Angioma Variety as contrasted with other Modes of Operation for Removal; by Dr. E. G. Janeway, of New York, on Abscess of the Liver; and by Dr. Austin Flint, Jr., of New York, on Typical Cases of Diabetes Mellitus not before reported.

DR. J. LEWIS SMITH, of New York, read a paper on

DIPHTHERITIC CROUP,

in which he contended that while the pathological appearances were practically identical in croup and in diphtheritic laryngitis and tracheitis, croup could exist without diphtheria, since before the appearance of the latter disease in New York a number of fatal cases of croup were reported each year. His main reliance in the treatment were alkaline inhalations, and to these he had lately been in the habit of adding *tripsin*, which was found largely in extractum pancreatis, and which was an excellent solvent for fibrine.

In the discussion which followed DR. GARRISH described the advantages of bichloride of mercury, DR. ROCHESTER those of insufflation of one part of iodoform to two of bismuth, DR. MOORE those of insufflation of bicarbonate of soda, and DR. REESE those of inhalations of kerosene.

DR. ROSS, of Chemung County, reported a case of

RUPTURE OF THE UTERUS.

It occurred during labor at full term, and the child, membranes, and placenta all escaped into the abdominal cavity together. Dr. Ross believed this to be the second case of the kind on record.

DR. BONTECOU, of Rensselaer County, exhibited

A CASE OF CONSERVATIVE SURGERY.

The patient received a severe gun-shot injury of the shoulder-joint during the war, and resection was afterwards performed, care being taken that as much as possible of the periosteum should be left. The result

was that several inches of the humerus were reformed by nature.

The following papers were read by title: Stretching of the Nasal and Intra-Orbital Nerves in Ciliary Neuralgia, by Dr. Ross, of Chemung County; Organic Disease of the Brain not a Constant Factor in Insanity, by Dr. Clark, of Niagara County; Supporting the Perinæum in the Act of Parturition, by Dr. Hartmann, of New York; and a Case of Gun-Shot Wound of the Stomach, with Recovery, by Dr. Hinton, of New York.

DR. GOULEY, of New York, read a paper on a case of

LIGATURE OF THE PRIMITIVE ILIAC ARTERY FOR DIFFUSE ANEURISM OF THE EXTERNAL ILIAC ARTERY.

Dr. Gouley regretted that he had not applied a second ligature and opened the sac, in which case he thought the patient's life might have been saved. As it was the walls of the sac sloughed, and the man died on the nineteenth day after the operation of pyæmia.

The paper was discussed by Dr. Moore, of Rochester, Dr. Fifield, of Boston, and Dr. Naucrede, of Philadelphia.

The Association then adjourned.

In the evening the Association was entertained at a banquet at the Murray Hill Hotel by the Fellows residing in New York. And on Friday, the 21st, surgical cases and operations, and an exhibition of various forms of bacilli, were seen at Bellevue Hospital, after which there was an excursion to the hospitals and other institutions on Blackwell's, Ward's, and Randall's Island under the charge of the Commissioners of Charities and Correction.

SPECIAL MEETING OF THE BOSTON MEDICAL LIBRARY ASSOCIATION FOR THE PRESENTATION OF A BUST OF THE LATE DR. J. MARION SIMS.

NOVEMBER 25, 1884. DR. OLIVER WENDELL HOLMES, President.

A special meeting of the Boston Medical Library Association was held Tuesday evening, November 25th, to accept the gift of a bronze bust of the late Dr. J. Marion Sims from an anonymous donor. About one hundred members of the Association, as well as some distinguished strangers, were present when the meeting was called to order by the presiding officer, Dr. Holmes.

The presentation of the bust, which was regarded by those present as an admirable likeness of Dr. Sims, — especially in profile and three-quarters view, — was made by Dr. JAMES R. CHADWICK in the following words: —

Mr. President and Members of the Boston Medical Library Association, — Few of you who were present at the exercises held in this city a year ago, to commemorate the hundredth anniversary of the foundation of the Medical School of Harvard University and the dedication of its new building, will have failed to observe upon the platform the close shaven features and the erect form of the world-renowned gynecologist, Dr. J. Marion Sims. He looked the personification of health, so that the news of his sudden death within a month must have filled you all with sorrow. On the day after those ceremonies I had intrusted to my professional care by Dr. Sims a lady whose affection and gratitude he had richly earned by saving her life by a surgical operation and by subsequent assiduous attentions.

A month after his death I was invited to act upon the committee charged with raising a memorial fund with which to erect in Central Park, New York, a statue of Dr. Sims. On asking his former patient to give practical evidence of her oft expressed sense of gratitude to Dr. Sims, I was met by a refusal, on the ground that the form the memorial was to take was ill suited to keep alive his memory among that class of the community — the medical profession — which in future ages would alone be qualified to appreciate his life work at its true value. To meet this not unnatural sentiment I then suggested her placing in this hall, which is likely long to be the place of union of all the medical societies of this city, a bust of Dr. Sims. To this she at once assented and authorized me to order the bronze bust which I now have the honor of presenting to this association with the single condition that the donor's name should not be revealed. The bust was taken about three years ago, as a personal favor, by Dubois, the greatest living French sculptor. It represents Dr. Sims in his prime, and both as a likeness and as a work of art cannot be surpassed by any piece of modern sculpture.

Dr. J. Marion Sims was born in Lancaster District, South Carolina, January 25, 1813. Having received his medical degree from Jefferson College, Philadelphia, in 1834, he practiced his profession in and about Montgomery, Ala., until 1852, when, reduced almost to a skeleton by a persistent chronic diarrhœa, he moved to New York and there established himself. For the remainder of his life he divided his time between New York and Europe, finding a host of patients of the highest social position on both continents ever claiming his professional services. The highest honor was bestowed upon him by the profession of his native country, and the sovereigns of Europe vied with each other in covering him with their coveted decorations. He died suddenly of heart disease in New York on November 13, 1883.

The life work of Dr. Sims is too recent and the merits of his individual achievements too indeterminate to make it proper for us to estimate them now and here. The one salient fact of his career dominates all other considerations, that by his ingenuity, pertinacity, and enthusiasm he did more than any other man in the history of the world to stimulate the study of the diseases peculiar to the female sex and to lead up to their present successful treatment. This is enough to entitle him to the gratitude of our own and of all future generations.

The President, DR. HOLMES, on accepting the gift in behalf of the Association, said: In accepting the gift of the bust of Dr. J. Marion Sims to the Boston Medical Library Association, it is my pleasant duty, as President of that Association, to express our gratitude to the donor for this most acceptable present. Unfortunately, we do not know whom we are to thank. *Stat nominis umbra.* The name of the giver is not to be found on the pedestal but in the shadow of the bronze effigy. We can only draw our bow at a venture and discharge our thanks, trusting that they will find the object of which they are in search.

This bust is well entitled to a place of honor in our library. Dr. Sims stands upon record as one of those benefactors of the race whose contributions to human

welfare are found all along the pages of the history of medicine. They are not emblazoned like the exploits of the conqueror, but they are no less victories. Nor do I know any forms of human suffering which it gladdens us more to relieve than the agonies and the injuries which a mysterious arrangement of nature has made inseparable from the lot of woman, the mother of mankind. It was in this sphere of medical art that Dr. Sims chiefly labored, and to this that he made his invaluable contributions. It is not for me to remind you of his ingenious inventions and operations. They are well known to all who are engaged in treating the diseases of women; that is, not merely specialists, but all family physicians, and they will carry his name to posterity on the list of those who have deserved the grateful remembrance of all mankind.

Let us hope that this bust will not stand alone, but that our profession will send forth many a master of his calling, who shall deserve to have his features reproduced in imperishable shape, and that future benefactors, known or unknown, will emulate the donor whom we thank this evening, and preserve their lineaments in bronze or marble.

DR. GEORGE H. LYMAN, being called upon by the Chair, made the following remarks: —

I respond very cheerfully, Mr. President, to the invitation to say something of Dr. Sims and his work, though all that can be said in a few words has, perhaps, been already uttered by yourself and Dr. Chadwick.

When I reflect upon the complete revolution which has taken place in that particular department of our calling with which Dr. Sims's name is so closely associated, and see so many representative men assembled to do honor to this occasion, it brings back to me very forcibly the beginning of my professional life some forty years ago. Returning from Paris full of zeal and enthusiasm, I brought with me the teachings of Jobert and others who were then beginning to feel their way in gynæcology. Of course I had a speculum or two as a part of my armamentarium. I soon learned, however, that my older friends by no means partook of my enthusiasm, and that unless I wished the reputation of an "irregular," I must be cautious how I encouraged such new-fangled notions. Still later, when ovariotomy was beginning to force its way against all manner of vituperation, a paper was called for as to the circumstances under which such an operation was justifiable! The result, among other things, was a collection of statistics which showed that up to that period only 300 well-authenticated operations had been performed throughout the world, with a mortality of some forty per cent. Now, on the other hand, there are numbers of individual operators who have done more than that, the experience of a few reaching to four or five times that number, and with a mortality varying from five to twenty per cent. Nowadays the use of the speculum, then so much derided, has become as common as the use of the stethoscope, and every well-informed practitioner employs it in suitable cases. The various chronic affections of the uterus and appendages, then so little understood, are now subject to a rational and very successful treatment. All this has gradually led to the recent wonderful advances in peritoneal surgery which fairly constitute a distinct era in the history of medicine, surpassed by nothing, perhaps, unless it be the discovery of ether.

These remarks, Mr. Chairman, will not seem irrelevant when we remember the large contribution to this progress which we owe to the distinguished man to honor whom, by placing his bust in our hall, we meet here to-night. None have done more, few as much, in this special department, and it is well for our own sakes and as a stimulus to those who are to come after, that this admirable memorial of him should be in constant view.

It was my good fortune to have known Dr. Sims for many years, and always as the most charming and genial of men. He was an enthusiast, as all progressive men must be, but he was earnest and honest with it all. His place in the medical history of this century will be, if not that of the originator of modern gynæcology, at least that of one who did the most for its advancement.

The evidences of this high appreciation of him are not confined to his native country. Frequent visits to Europe made his name and fame widespread in England and on the Continent, and honors were showered upon him with a liberal hand. His numerous operations there did much for the honor of American gynæcology, and already its students are so looking to this country for the latest and best information that we may expect them to come to us to find their best facilities among our American teachers.

The meeting adjourned soon after nine o'clock, and an agreeable hour was spent in the examination of autographs and diagrams recently presented, and the discussion of an informal collation.

NEW YORK ACADEMY OF MEDICINE.

THE SURGICAL MANAGEMENT OF RACHITIC DEFORMITIES OF THE LOWER EXTREMITIES.

AT a meeting of the Academy held November 20th, DR. V. P. GIBNEY read a paper on the above subject. Having devoted some introductory remarks to terms and definitions, he expressed the conviction that a fair proportion of cases of the deformities referred to recovered spontaneously. This opinion was based on the results which he had witnessed at the Hospital for Ruptured and Crippled on Forty-second Street, with which he had been connected for a number of years. Between the years 1871 and 1877 255 cases of genu valgum under fourteen years of age had been observed at that institution. Where apparatus was used it consisted of external and internal steel springs, of moderate strength. The larger number of osteotomies were performed in children between the ages of three and eight. One reason why he thought a large number of cases recovered spontaneously was because no adults with such deformities were met with in the city. Of 1005 cases of bow-legs treated at the Forty-second Street Hospital, 997 were under fourteen, three in adults, and five between fourteen and twenty.

He then proceeded to inquire what cases could safely be left to nature. In children under two years he would not advise apparatus or operative interference unless the deformity was extreme. In those between two and three, with a moderate degree of deformity, he would also leave the case to nature; but would examine the condition of the bones very carefully and have the patient kept under close observation. As knock-knee and bow-legs were due, as a rule, to rachitis, medicinal and hygienic would naturally constitute an important element in the treatment, and he had known

cases in which these deformities entirely disappeared during a sojourn in the country.

In case the bones were found to be yielding, he advised the use of manual force under certain circumstances, as, for instance, when parents were too poor to purchase apparatus or too improvident to look after it properly, and when there was little time in which to effect a cure. In one case where the child's parents were poor Italians he had broken the femur, tibia, and fibula on both sides.

In the matter of apparatus he thought Mr. Wm. J. Little stood at the head. He placed no limit upon the efficacy of splints, and undoubtedly cured with them many cases in which most surgeons would have adopted operative procedures. All the springs now in use acted on the principle of the bringing to bear of force against the convexity of the curve at its apex. Having remarked that osteoclasis had never been popular in this country, Dr. Gibney went on to speak of osteotomy, and referred to the brilliant success of McEwen with this operation. At the International Medical Congress at Copenhagen he had reported 820 personal osteotomies, in only eight of which did any suppuration occur. Five of the patients died, but in not one of them was the fatal result due to the operation. Severe arterial hæmorrhage in this operation had been reported by some surgeons, and in one case of his own he had had alarming hæmorrhage from the bone itself. He then described a case in which he had performed it in anterior tibial deformity, a condition in which he said he had never seen any effect produced by apparatus. In this instance the child had worn apparatus for twelve months prior to the operation. Dr. Gibney had performed nine linear osteotomies during the past six months at the New York Polyclynic, and he was in the habit of sending patients home as soon after the operation as the plaster dressing had become hard.

The lessons which he said he had learned in regard to this procedure were as follows: —

(1.) Exaggerate the curvature of deformity.

(2.) Examine the limb at the end of a week to ascertain whether the amount of curvature is the amount desired.

(3.) Do not hesitate to refracture by manual force, if it be necessary.

(4.) In dispensary cases do all the operating that you propose at one sitting.

Strict listerism was to be employed during the operation, and after it three months was not too long for the patient to wear some form of support. McEwen, he thought, had convinced every one that supra-condyloid osteotomy was the only one for *genu valgum*.

Dr. Joseph C. Bryant agreed with Dr. Gibney that there were a large number of cases which could be safely left to nature. No better proof of this could be desired, he thought, than could be afforded by a visit to some of the districts of the city occupied by poor blacks and Italians. The number of cases of such deformities among this class of the population was exceedingly large; yet when those who had suffered from them in childhood had grown up the deformities were usually found to have disappeared. In speaking of the treatment by manual force he said that if in connection with a case of bow-legs he found that the bones were springy, he would endeavor to correct the deformity by forcible pressure upon the point of greatest convexity, repeated two or three times. In one case of sharp anterior tibial curvature he found it necessary to divide the *tendo Achillis*. At the first operation he reduced the deformity two thirds, and then repeating the forcible pressure three times a week, in six weeks he secured a perfectly straight tibia. In a case of this kind he considered manual force better than osteotomy. In regard to osteoclasis he said that he would certainly never use it in the vicinity of a joint, as would be necessary in cases of genu valgum. Osteotomy he considered one of the important advances in surgery of the century. He always performed it with strict antiseptic precautions, and had never seen a drop of pus after any of his operations. It was apparently called for in all cases which had reached a stage where consolidation of the bones had taken place.

Dr. Charles T. Poore thought that rachitical deformities were more common now than formerly. There was no question that in the earlier stages of rachitis the bones could be bent, but he had not seen spontaneous recovery when the bones had become hardened. In regard to osteotomy he thought that the cases which had gone badly (as from hæmorrhage from arteries, etc.) were due, as a rule, to accidents which might have been avoided. In his own cases he had never kept the patient in bed more than five weeks, and at the end of four weeks he usually took off the plaster dressing. He had never seen a recurrence of the deformity. In correcting the deformity of bow-legs he considered the osteoclast better than manual force, care being taken never to fracture the bone within three inches of the condyles. He had had no experience in trying to bend bones without an instrument, and it must be very hard work. In osteotomy he did not use listerism, strictly speaking, and did not dress the wound after McEwen's plan, always endeavoring to secure primary union.

Dr. M. H. Henry said that at the Emigrant's Hospital he had seen a large number of young children, born in Europe, arrive with rachitical deformities of the legs, but under the good hygienic conditions with which they were there surrounded they all seemed to recover without surgical interference. The limit of their stay was five years.

Dr. M. J. Roberts made some extended remarks, in the course of which he said that while many of the cases might recover spontaneously the process was a slow one, and with the aid of appropriate apparatus the cure could be effected in half the time. Every case, therefore, in his opinion, ought to receive treatment if possible. In speaking of osteotomy he described an electro-osteotomy which he had devised, by means of which the femur of a child could be sawn through with perfect ease in two minutes, and of an adult in five minutes.

Dr. Gibney closed the discussion, and in reply to an inquiry from the President, Dr. Barker, said that he had not noticed any difference between the sexes as to frequency or curability of the disease. He had noticed, however, that a good many women who suffered from flat-foot had had bow-legs when they were children.

— The forty-second annual meeting of the New York Society for the Relief of Widows and Orphans of Medical Men was held at the hall of the Academy of Medicine on the evening of November 26th.

CHICAGO MEDICAL SOCIETY.

L. H. MONTGOMERY, M. D., SECRETARY.

STATED meeting, November 10, 1884.
DR. EDMUND ANDREWS reported

TWO CASES OF GASTROSTOMY.

He stated that the term itself was a barbarous one, — an etymological blunder so far as literary usages are concerned, — composed partly of Greek and partly of Latin, the "philological monstrosity" being, apparently, an attempt by its author to enlarge the word gastrotomy, which literally signifies stomach-cutting, and by the addition of a syllable to signify a mouth, so as to make the compound mean a cutting of the stomach to make a mouth, literally a stomach-mouth cutting. He said the word should be gastrostomaty, and even then there would be nothing left in the compound to signify the "cutting;" therefore to express the full meaning of "stomach-mouth-cutting" would require the form gastro-stomatomy, a term whose length and harshness of sound is sufficient for its condemnation. The following is a brief synopsis of the balance of the paper.

CASE I. was a little girl, aged six years, who swallowed some concentrated lye several months previously, cauterizing the lower part of the œsophagus, and gradually inducing a stricture. Dr. E. P. Cook, of Mendota, Ill., dilated the stricture, after which the child was sent home greatly improved, but after leaving his care she relapsed, and was then placed in care of the writer. Upon her arrival it was ascertained that she had been unable to swallow anything for a number of days. Dilatation was essayed, and the patient improved for a time, regaining a partial power at least of swallowing liquid food. However, it was soon perceived that the advantage thus gained could not be maintained, and after faithful trial it became evident that the little one was gradually starving. So-called gastrostomy was then performed in a room which had been sprayed for an hour with carbolic acid, but the spray was not permitted to touch the peritonæum. The usual incision was made in the hypochondrium from the xyphoid cartilage downward and to the patient's left. The colon was found partly in the way, but it was easily pushed downward. The stomach was then drawn out with long toothed forceps. The viscus was identified by the relations of the gastro-epiploica vein, and secured to the abdominal wall by a long suture on each side, as it was feared starvation would ensue were not this plan pursued, and the patient's life be still further jeopardized. The stomach was opened at once, and its edges *sewed* closely to the skin all around the incision. There was a good deal of shock, but reaction occurred, and union by first intention followed without difficulty and with no peritonitis. Peptonized food was regularly inserted, and on inspection was found perfectly digested except when meat was used. This, whether raw or cooked, would be ejected from the wound unchanged even when retained twenty-four hours. For some days the patient improved, but it soon became evident that most of the food, though digested, did not pass through the pylorus. It seemed that this orifice of the stomach required a little pressure to unfold it, and that whenever the stomach contracted for the purpose the chyme escaped by the fistula into the dressings, and did not pass on into the intestines. A rubber pad tight enough to stop the outflow could not be tolerated. A soft rubber tube with a flange and valve was substituted, in which the inner disc could be adjusted to the inner wall of the stomach; then by clamping the tube outside of the outer disk to the wall of the abdomen a perfect valve was obtained which prevented leakage. The effect of the inner disk on the walls of the stomach was feared at first, but it produced no perceptible irritation. The opening in the stomach was purposely made pretty large, the surgeon hoping at a future time to introduce a finger upward into the lower end of the œsophagus, and then by pushing down upon it to succeed in restoring the natural passage. As above stated, the valve retained the food perfectly, and the patient took an abundance, and even learned to know when she was hungry, and to call for her meals. The improvement was but temporary, however, and she began slowly to fail again without obvious cause. The power of assimilation seemed to have exhausted itself. She constantly grew weaker, and died the thirty-sixth day after the operation.

CASE II. An adult male patient. Six months previously he swallowed some caustic ammonia, producing a contracting ulcer of the lower part of the œsophagus. In September last he placed himself in the care of the writer, having been unable to swallow anything for some days. By a persistent use of bougies the stricture was dilated, and the power to swallow liquid food restored. He then returned home, having learned to introduce the bougie himself. In time, however, he lost the art of passing the instrument, and in October returned in the same condition as before. Diligent trials to dilate the stricture a second time gained only a slight temporary power of passing small quantities of liquids a day or two at a time, and within a week or so it was perceived that his progress was downward, and that he was slowly starving. Moreover, the points of the bougies seemed to be creating a local inflammation in the right lung, as if making a false passage in that direction. To continue their use, therefore, was not deemed judicious, and an operation was decided on at once. The operation was the same as in the former case except that the opening was smaller. The same difficulty of regurgitation of the food occurred, and was controlled by a similar valve. The patient was doing well thirty-two days after the operation, and bids fair to recover.

The statistics of this operation are not very encouraging. Of 207 recorded cases forty were for cicatricial stricture of the œsophagus like those above cited. Of these forty twenty-one died. Yet when no other hope of life or relief is offered, an operation which gives one chance in two is a great benefit.

EXCISION OF THE RECTUM

was the next subject, of which DR. ANDREWS reported two cases, at present under treatment.

CASE I. An epithelioma not involving the border of the anus. In operating the entire external sphincter was saved. The incision was carried from an inch in front of the anus back to the coccyx, opening the anus antero-posteriorly, and cutting off the gut just above the verge. After dissecting it upward a little and tying numerous vessels the rectum was separated from the pelvic chamber mainly by the finger, and the *tube* divided about three inches upward just above the

top of the growth. There was no shock and not much subsequent pain or inflammation.

CASE II. was almost exactly a repetition of the first except that the verge of the anus was involved in the disease, and consequently was dissected out with the rest. Both patients were doing well and very comfortable at the time of the report.

Statistics. The statistics are much like those of epithelioma elsewhere. Billroth, of Vienna, thinks he permanently saves about one third of the cases. Of 608 collected cases 140 died of the operation, and of 100 of those who survived the operation, whose accounts were traced up, thirty-one were doing well at the end of one year, and seventeen were alive and well with no return at the end of three years.

LITHOLOPAXY.

DR. ANDREWS reported having operated twenty-three times with one death. He is confident that the plan he pursued of keeping the nerves of the bladder benumbed during the operation by filling it with carbolized water tends greatly to prevent both shock and inflammation. He thought it worthy of inquiry whether the remarkable local anæsthetizing properties of the new agent, cocaine, would not enable us to operate without ether and without producing shock. . . .

A NEW INSTRUMENT FOR OPERATING ON VARICOCELE

was the next topic discussed by Dr. Andrews. Operations for destroying the veins in varicocele have occasionally produced death, and in other cases resulted in neuralgic scrotum, with or without atrophy of the testicle. Many surgeons have followed the lead of Prof. Frank Hamilton in preferring Sir Astley Cooper's plan of shortening the scrotum sufficiently to make it its own suspensory bag. This operation is vexatious because the imperfect character of the old-fashioned adhesive plasters rendered it difficult to support the sutures sufficiently to secure union by first intention. Now that we have the rubber plaster, which never lets go its grip, we can cut the scrotum very short and still hold the wound firmly together and secure a triumphant success. Sundry clamps have been invented to hold the skin of the scrotum firmly while the surgeon cut it off and sewed it up; the evil of the clamp is that it compresses the arteries so that after cutting away the pouch the surgeon is unable to find and ligate the vessels. If he sews up the wound without attending to this point, experience shows that after the clamp is removed hæmorrhage often takes place inside the scrotum, distending it with clot and forcing open the wound, thus delaying the cure. To meet this difficulty Dr. Andrews has devised a kind of "varicocele bow," which he exhibited and described as follows: It consists of two curved parallel bows connected at the ends and inclosing a slot three eighths of an inch wide between them. Twelve holes are drilled through the bars of a size to admit ordinary pins. The surgeon draws the scrotum through the slot (having the concave border towards the base of the scrotum) to such a distance as he deems sufficient, secures it there by inserting, one by one, as many pins as he finds necessary to hold the pouch securely. He then cuts off the scrotum outside the convex border of the bars. As the scrotum is not pinched by the instrument the blood spouts freely, especially from the artery of the raphe. The operator can carefully and deliberately secure every bleeding point, which being accomplished he sews the cut edges together, and then drawing out the pins removes the bow and applies his plasters. The neatness and despatch of the operation are thus greatly enhanced.

REPORT OF COMMITTEE ON NATIONAL SANITATION.

DR. JOHN BARTLETT, on behalf of the Committee on National Sanitation, presented the following preamble and resolutions: —

MR. PRESIDENT, — The committee appointed at the meeting of this Society September 15, 1884, to consider and report upon a series of resolutions presented by Dr. L. H. Montgomery, having reference to national sanitary matters, respectfully report the following preamble and resolutions as suitable to be adopted: —

Whereas, Experience has firmly established the fact that the ravages of certain infectious and contagious diseases may be in good measure prevented, controlled, or arrested by the enforcement of suitable sanitary regulations; and

Whereas, The United States is constantly exposed to the importation of disease from foreign countries, and, because of the facility and rapidity of inter-state transit, to the rapid spread of infection once finding lodgment on our borders; and

Whereas, This exposure, because of the prevalence of cholera in Europe, is just now unusually great; and

Whereas, The facts are that matters of sanitation are in some of the States of this Union entirely neglected, while in others they are simply taken cognizance of by the appointments of Boards of Health, in their functions advisory only, and not clothed with powers of authoritative action; and

Whereas, Either of these State Boards of Health, as now constituted, may prove derelict or inefficient in its duties, or act without concert with, or even in antagonism to, the Boards of other States; and

Wheaeas, The exigencies occasioned by the appearance of violent epidemics demand organized means for the prompt recognition of the outbreak of disease, and vested authority, limited in its area by the boundaries of the country only, to take such immediate steps in matters of protection as vaccination, isolation, quarantine, etc., as experience has taught to be useful; and

Whereas, No national authority in sanitary matters now exists; therefore

Resolved, That it is the judgment of the Chicago Medical Society that the sanitary interests of the United States demand the establishment of a national health authority, which shall have for its main functions the detection of pestilential and epidemic diseases, and the enforcement, where necessary, of sanitary regulations tending to prevent, to abate, or to suppress them.

Resolved, That as a step toward the consummation of the idea suggested in the foregoing resolution a committee of three be appointed by this Society to collate facts tending to show the usefulness and necessity of a national sanitary organization, and to compile the same in such form as may be available for disseminating information upon, and creating an interest in, national sanitary legislation.

Resolved, That the said committee be empowered and instructed to urge the importance of national sanitary legislation upon the attention of the congressional delegation from Illinois, and fittingly to present the subject to the representatives of the people in both houses of Congress.

O. C. DE WOLF, *Chairman.*

Upon motion, duly seconded, the resolutions were voted upon *seriatim*, and were carried unanimously, when they were again read. The suggestions embodied in the report were unanimously adopted, and Drs. John Bartlett, R. E. Starkweather, and J. H. Hollister were appointed members of the committee.

After which two papers were read on Hydrochlorate of Cocaine.

DR. BOERNE BETTMAN reported some cases illustrating the use of

HYDROCHLORATE OF COCAINE AS A LOCAL ANÆSTHETIC.

CASE I. Oloff D., aged twenty-two, consulted the writer for a stricture of the nasal duct. A few drops

of a solution of cocaine produced complete anæsthesia in three minutes. A Weber's knife was introduced into the canaliculus, shoved forward into the sac, and the duct slit open with but trifling pain to the patient. With an Auel's syringe a few drops of cocaine were injected into the nose. Five minutes later the firm stricture was forced with a Bowman's probe. The pain, according to the patient's statement, was seventy-five per cent. less than that experienced five years ago when subjected to a similar operation. Anæsthesia lasted fifteen minutes.

CASE II. A piece of steel had been imbedded in the cornea of a policeman for two days. The eye was extremely sensitive. Two drops of cocaine benumbed the eye in three minutes. The digging out of the mote with a spud was painless.

CASE III. Mr. M. complained of severe earache, produced by an otitis media acuta purulenta. The introduction of a cotton holder or speculum was not permitted. Instillation of two drops of cocaine was followed by almost immediate cessation of pain, when the ear could be manipulated without the slightest annoyance to the patient.

CASE IV. The most striking results were obtained in the case of Mrs. T., on whose right eye an operation for cataract was performed. Several drops of cocaine applied every few minutes produced complete anæsthesia in ten minutes. The corneal section was made without the patient being aware of the fact. The only step in the operation which caused the slightest pain was excision of the iris. At this stage, when questioned about the sensation, the patient remarked that it felt as if a pin were pricking her.

The physiological and therapeutical effects of this remedy may be tabulated as follows: —

First. Hydrochlorate of cocaine is a powerful local anæsthetic, not penetrating in nature, rapid in its effects, which, however, are only temporary.

Second. It is a mydriatic, the effect of which is regulated by the strength of the solution.

Third. It produces paralysis of the ciliary muscle, the near point receding from the eye, distant vision is not influenced.

Fourth. By virtue of its benumbing powers it may be classified as an anodyne.

DR. JEFFERSON BETTMAN reported a case of

ASTHMA NERVOSUM,

illustrating the applicability of muriate of cocaine in nasal surgery: —

Dr. K., a physician, had been under treatment suffering from asthma nervosum. The asthma is purely reflex, induced by great hypertrophy of both inferior turbinated bones, excepting an occasional obstruction to free nasal respiration, but little discomfort is experienced during the day. A recumbent position, the warmth of the bedding, are sufficient to produce a reflex turgescence of the lower turbinated bones, a subsequent serous discharge, and, to complete the clinical picture, a culminating violent attack of asthma. The nares are extraordinarily hypersensitive. The introduction of any instrument into the nose is exquisitely painful. Previous treatment had consisted in applications of the galvano-cautery to reduce the volume of the erectile tissue in the nose. The abnormal sensitiveness would only permit of superficial cauterizations, so the results obtained were but partially successful. On the 8th of the present month the writer resolved to apply the muriate of cocaine prior to cauterization. A pledget of cotton of sufficient size was soaked with fifteen drops of a four per cent. solution of the remedy and placed in the inferior meatus of the left nostril. At the expiration of ten minutes the nostril was perfectly anæsthetized. At the end of a quarter of an hour the plug was removed and the parts thoroughly cauterized with a sharp-cutting electrode. The period of application exceeded three seconds and produced but a minimum degree of pain. In fact, the discomfort was so trifling that the hitherto sensitive colleague cheerfully submitted to a second vigorous application at the same sitting. After a period of twenty-five minutes sensibility of the parts was fully restored.

At a very late hour a motion prevailed that the Society do now adjourn.

Recent Literature.

An Introduction to Pathology and Morbid Anatomy. By T. HENRY GREEN, M. D. Philadelphia: Henry C. Lea's Son & Co. 1884. Fifth American from the Sixth Revised and Enlarged English Edition.

With the existence of so much better books on the subject as Ziegler's text-book and Coat's Manual of Pathological Anatomy it is not at first sight evident why another edition of the above work is needed. All that can be said in its favor is that the style in which it is written is quite easy reading, probably from the diffuse way in which the subject is treated. The author has tried to infuse new life into it by having some chapters written by a colleague, Mr. Stanley Boyd, those on Tumors, Degeneration, Septicæmia and Pyæmia, and Vegetable Parasites. Even with a new handle and a new blade we fear that it will always be the same knife. The publishers have done well in rendering the volume attractive.

A Text-Book of Pathological Anatomy and Pathogenesis. By ERNST ZIEGLER. Translated from the German by DONALD MACALLISTER, M. A., M. B. Part II. Special Pathological Anatomy. Sections I.–VIII. London: Macmillan & Co. 1884.

We are glad to welcome the continuation of Professor Ziegler's valuable work. The first part, treating of general pathology, has already been noticed. This volume treats of the Changes in the Blood and Lymph, the Vascular Mechanism, the Spleen and Lymphatic Glands, the Serous Membranes, the Skin, the Mucous Membranes, the Alimentary Tract, and the Liver and Pancreas.

The descriptions are concise, perhaps too much so for easy reading, but abundant cross reference renders them very intelligible, and at the same time does away with a great deal of repetition. The accounts are further augmented by an index to the principal articles, from which a more extended knowledge of each particular subject can be obtained by one desiring to do so. The author is, perhaps, inclined to be a little positive in his statements, but he at least writes as one who has seen and studied most of the changes referred to, and therefore has a right to an opinion of his own. The text is well illustrated by numerous good wood-

cuts of microscopic appearances, most of which are original. There is certainly nothing better in English than this, and thanks are again due to Mr. Macallister for his admirable translation, and a speedy completion of the work is greatly to be wished. The name of the publishers is the guarantee of a handsome volume.

Medical and Surgical Journal.

THURSDAY, DECEMBER 4, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by Houghton, Mifflin and Company, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 Park Street, Boston, Mass.

THE ACCOUNTABILITY OF MEDICAL MEN. COMMONWEALTH *vs.* FRANKLIN PIERCE.

"The accountability of medical men has been a fruitful source of lego-medical discussion, and in early times was the subject of much variety of judicial, as it is still of popular, sentiment." Thus reads the first sentence of the chapter on common law practice in criminal prosecutions for medical malpractice in Wharton and Stillé's Medical Jurisprudence. It has had a forcible illustration lately in the case of the Commonwealth *vs.* Franklin Pierce before the Supreme Judicial Court of Massachusetts.

The defendant was tried last May before the Superior Court of Worcester County on an indictment for manslaughter, and the jury returned a verdict of guilty on evidence that he publicly practiced as a physician, and being called to attend a sick woman caused her, with her consent, to be kept wrapped in flannels saturated with kerosene oil for three days, more or less, by means of which she died. There was evidence that he had made similar applications with favorable results in other cases, but that in one the effect had been to blister and burn the flesh, as in the present case.

The defendant alleged exceptions to rulings and refusals to rule of the presiding judge of the Superior Court, relying largely upon the famous case of Commonwealth *vs.* Thompson, decided in 1809 (6 Mass. 134). Thompson was the originator of the system of practice which, under the name of Thompsonianism, gained so much notoriety in the earlier part of this century. The case for which he was indicted was as aggravated an instance of reckless malpractice with a fatal result as can be found in the annals of any court. Yet he was acquitted, the judicial ruling emanating from no less a worthy than Chief Justice Parsons, who held that to constitute manslaughter the killing must have been the result of some unlawful act, but, there being no law prohibiting any man from prescribing for a sick person, with his consent, if he honestly intend to cure him by his prescription, the prisoner should be acquitted.

Since 1830, certainly, the case of Thompson has not generally been held to be sound law, and, moreover, doubt has been thrown upon the exactness of the report of the judicial ruling.

Wharton and Stillé give the following propositions representing the law as deduced from the leading cases in this country and England: —

(1.) If the defendant acted honestly, and used his best skill to cure, and it does not appear that he thrust himself in the place of a competent person, it makes no difference whether he was at the time a regular physician or surgeon or not. (2.) To constitute guilt, gross ignorance or negligence must be proved. (3.) A defendant who, with competent knowledge, makes a mistake in a remedy, is not answerable; but it is otherwise when a violent remedy, shown to have occasioned death, is administered by a person grossly ignorant but with average capacity, in which case malice is presumed in the same way that it is presumed when a man *compos mentis* lets loose a mad bull into a thoroughfare, or casts down a log of wood on a crowd. (4.) Where competent medical aid can be had, the application of violent remedies, by an ignorant person, though with the best motives, involves him in criminal responsibility. (5.) Express malice, or an intent to commit a personal or social wrong, makes the practitioner criminally responsible in all cases of mischief.

In presenting the case of the Commonwealth against Pierce the Attorney General remarked: At common law, a private person guilty of gross negligence in the performance of a lawful act is guilty of manslaughter; the ordinary person is so guilty; is he then to be acquitted the moment he assumes the position of surgeon or physician? "Licensed to kill," as the old jest goes? Medicine is a useful profession — so is a switchman's, a pilot's, a policeman's; and a pilot's or captain's is not judged by the knowledge of an ordinary man of the rocks and shoals and other dangers of navigation; but by that ordinarily possessed by pilots and captains. An ordinary man does not know how to turn a switch; but a switchman is bound to turn it the right way; if he does not do so, it is manslaughter.

Judge Holmes delivered the decision of the Supreme Court, sustaining the rulings of the justice of the Superior Court and overruling the defendant's exceptions. The opinion as delivered was substantially as follows: —

The defendant has been found guilty of manslaughter on evidence that he publicly practiced as a physician, and, being called to attend a sick woman, caused her, with her consent, to be kept in flannels saturated with kerosene for three days, more or less, by reason of which she died. There was evidence that he had made similar applications with favorable results in other cases, but that in one the effect had been to blister and burn the flesh as in the present case. The main questions which have been argued before us are raised by the fifth and sixth rulings requested on behalf of the defendant, but refused by the court, and by the instructions given upon the same matter. The fifth request was, substantially, that the defendant must have so much knowledge or probable information of the fatal tendency of the prescription that the death may be reasonably presumed by the jury to be the effect of obstinate, willful rashness, and not of an honest intent and expectation to cure. The sixth re-

quest was as follows. "If the defendant made the prescription with an honest purpose and intent to cure the deceased, he is not guilty of this offense, however gross his ignorance of the quality and tendency of the remedy prescribed or of the nature of the disease, or of both." The court instructed the jury that it was not necessary to show an evil intent; that if by gross and reckless negligence he caused the death he is guilty of culpable homicide; that the question is whether the kerosene, if it was the cause of the death, either in its original application, renewal, or continuance, was applied as the result of foolhardy presumption or gross negligence on the part of the defendant, and that the defendant was to be tried by no other or higher standard of skill or learning than that which he necessarily assumed in treating her; that he was able to do so without gross recklessness or foolhardy presumption in making it. In other words, that the defendant's duty was not enhanced by any express or implied contract, but that he was bound at his peril to do no grossly reckless act, when he intermeddled with the person of another, in the absence of any emergency or other exceptional circumstances. The defendant relies on the case of the Commonwealth *vs.* Thompson, 6 Mass., 134, 1809, from which his fifth request is quoted. His argument is based on another quotation from the same opinion, which recites: "To constitute manslaughter the killing must have been a consequence of some unlawful act. Now there is no law which prohibits any man from prescribing for a sick person with his consent, if he honestly intends to cure him by his prescription." This language is ambiguous, and we must begin by disposing of a doubt to which it might give rise. If it means that the killing must be the consequence of an act which is unlawful for independent reasons, apart from its likelihood to kill, it is wrong. Such may once have been the law, but for a long time it has been just as fully, and, we may add, much more willingly, recognized, that a man may commit murder or manslaughter by doing otherwise lawful acts recklessly, as that he may be doing acts unlawfully for independent reasons, from which death actually ensues. But recklessness in a moral sense means a certain state of consciousness with reference to the consequences of one's acts, or the actual condition of the individual's mind with regard to the consequences, as distinguished from mere knowledge of present or past acts or circumstances, from which some one or everybody else might be led to anticipate or apprehend them if the supposed act was done.

The questions raised by the exceptions are whether an actual good intent and the expectations of good results are an absolute justification of acts, however foolhardy, when judged by the external standard, and whether the defendant's ignorance of the tendencies of kerosene administered as it was will excuse the administration of it. If the principle which has been established both for murder and manslaughter is adhered to, the defendant's intention to produce the opposite result from that which came to pass leaves him in the same position with regard to the present charge that he would have been in if he had had no intention at all in the matter. We think that the principle must be adhered to where, as here, the assumption to act as a physician was uncalled for by any sudden emergency, and no exceptional circumstances are shown, that we cannot recognize a privilege to do acts manifestly endangering human life on the ground of good intention alone. We have implied, however, in what we have said, and it is undoubtedly true as a general proposition, that a man's liability for his acts is determined by their tendency known to him, and not by their tendency under all circumstances actually affecting the result, whether known or unknown. The using of the thing must be dangerous according to common experience. If the danger is due to the specific tendencies of the individual, and is not characteristic of the class to which it belongs, a person to be made liable must have notice of some past experience. One cannot escape on the ground that he has less than the common experience. Common experience is necessary to the man of ordinary prudence, and when a man assumes to act as the defendant did he must have it (common experience) at his peril. When the defendant applied kerosene to the person of the deceased, in a way which the jury have found to have been reckless, or, in other words, seriously and unreasonably endangering life according to common experience, he did an act which his patient could not justify by her consent, and which, therefore, was an assault, notwithstanding that consent.

— Dr. C. P. Bancroft, Superintendent of the Concord, N. H., Insane Asylum, who was severely beaten on the head by a patient, is recovering from his injuries.

"TRICKS AND MANNERS."

IN previous numbers of the JOURNAL we have studied some of the words and curious expressions of our patients and found them interesting: their actions are equally deserving of regard. One who sits day after day in a hospital out-patient department watching a number of people who pass rapidly before him, each with his tale of woe, finds certain little peculiarities in their actions constantly recurring. By far the greater number of his patients grow confidential and urge their chair towards him. The patient's chair in the surgical room of the old Boston Dispensary will occur to those of our readers who were familiar with it. It was fastened to the floor, and the surgeon sat in front of it in a chair on casters so that he was able to approach or recede from his patient as circumstances dictated. With hardly an exception the patient as he sat down in the chair would give it a hitch to draw closer to the surgeon, and many, not satisfied with a single attempt, would try again and again to move it. In process of time the seat of the chair was actually torn away from the legs by these many wrenches. In other similar positions the surgeon's foot is almost automatically brought against the round of the patient's chair when this hitching process begins. This hitch is the result usually of a desire to pour into the doctor's private ear the object of the visit, or sometimes to give a better opportunity for close examination, but even when no reason exists the hitch is a moderately certain preliminary to a conversation. In extreme cases, when secrecy seems particularly desirable, the patient follows up the hitch by rising and whispering in the doctor's ear. Only particularly dirty patients who are perfumed with sweat, gin, and onions ever go to such a length.

There is an instinctive action on the part of many patients to feel with their own hands the spot which the doctor is exploring. Almost inevitably the patient's hands thus follow the doctor's in feeling for an enlarged gland in the groin, and only a little less certainly in searching for a broken rib. A similar fatality attends the putting of the double stethoscope to one's ears. It is a signal for the patient to open his mouth, and the most silent patient becomes garrulous under the stimulation.

To ask a patient to lie upon his back is, in a very large number of cases, followed by his turning his back upwards. The mention of his back gives the idea that that is the part of his body the doctor desires to see, and with great readiness to assist in the examination he pays no attention to the words that accompany it. Such excessive zeal to assist the doctor shows itself in many other ways. In examining a joint, unless movement is painful, the patient will often assist in a manner that renders the examination futile. But when it is desirable to examine the corresponding healthy joint for the sake of comparison even the too willing patient will insist that there is nothing the matter with that joint, and exposes it very unwillingly, and only after explanation of the reasons for its examination.

The mother who brings her child for examination

gives sometimes no little trouble by insisting on helping it when the doctor is specially desirous of seeing how it walks and moves. He throws an object on the floor, and asks the child to pick it up; the mother picks it up and tells the child to give it to the doctor. He asks the child to lie down, and the mother feels that she must help. Sometimes this extra help is of great service in showing the daily influence to which the child is subjected, but not of much use in helping the surgeon to diagnosticate the physical disabilities of the child. Children themselves are often a plague, and nowhere does a doctor's tact show itself more plainly than in his ability to gain their confidence and coöperation. To recognize the earliest stage of joint disease in a young child without its own assistance is almost an impossibility. Such coöperation is usually quite as easily obtained as that of grown people, but there are children — bless 'em — that practically refuse to do anything but yell. The rebel yell of rebellion days pales beside that unreasoning, unmeaning cry which increases when coaxed to stop, becomes frightful under threats, and continues unabated when left to follow its own sweet will.

It is always an annoyance and one only too frequently repeated to hear a child told that the doctor will carry him off or do some horrible act of mutilation if he does not behave. Parents who thus use the doctor as a bogy to frighten their little ones into good behavior can hardly blame the doctor if he fails to overcome in a single visit the prejudices they have so carefully implanted.

To the doctor the tongue proves itself most literally an unruly member. Patients will protrude but its tip when asked to show it, and push it out to its fullest extent when they open their mouths for inspection of the fauces, and on the application of a spatula it is sure to arch itself like a cat's back at the sight of a strange dog.

One of the most troublesome traits is the tendency to misquote previous opinions. We know how very difficult it is to repeat any conversation, but a peculiar difficulty seems to attach itself to the remarks of physicians. Doctors learn to be very skeptical in regard to the opinions attributed to their colleagues, especially after such an experience as that of a physician at a charitable institution who was consulted, not long ago, by a mother in behalf of her young child. In giving the history of the case she said that the little one had been sick almost since its birth; that a year ago she consulted Dr. ——, mentioning the name of the man with whom she was talking, but whom she had failed to recognize, and "he said the child had n't any inwards."

Another troublesome habit is that of attributing every untoward event to the medicine or at least in some way to the doctor. This is offset in great measure by similarly attributing to him favorable results to which he knows he can establish no valid claim. The two errors may be left to balance each other in establishing his reputation with the public, but his unwillingness to accept the responsibility in the first case ought to assist him in distinguishing in his own mind between *post* and *propter* in the second case.

THE SINGULAR MORTALITY REPORTED FROM WESTERN VIRGINIA AND EASTERN KENTUCKY.

A singular and very fatal disorder has been devastating the sparsely settled mountainous counties of Southwestern Virginia and Southeastern Kentucky. The afflicted district is said to embrace a strip of country about eighty miles long by seventy miles wide, extending through the portions of Lee and Wise Counties in Virginia, and those of Knox, Harlan, Letcher, and Pike Counties in Kentucky, situated upon the slopes of the Cumberland Mountains. A number of rivers have their source here, the Cumberland, the Kentucky, the Licking, and the Big Sandy flowing into the Ohio River. It is a region in which the railroad and the telegraph are unknown, and the inhabitants are dependent for a somewhat precarious livelihood upon the resources of a primitive agriculture.

It was lately reported that no rain had fallen in this region, until very recently, for several months; the limited crops had been a failure, the live stock were dying upon the hills, and the unfortunate inhabitants were themselves falling a sacrifice to a rapidly fatal malady of a choleraic character. This intelligence was supposed at first to be of a rather sensational character, but later, and apparently trustworthy, accounts tend to confirm the worst of what had been previously reported. It is now estimated that fully 1000 people have died of the disorder.

The water through all this district has been extremely low, the streams and springs on the mountain sides being nearly dried up. The little water which could be had, and which the inhabitants have been forced to drink, has been very strongly impregnated with mineral substances, and perhaps also with decaying vegetation. As yet we have seen no accurate analysis of it. The malady as manifesting itself is accompanied, it is said, by intense thirst, by griping pains in the abdomen, and frequent profuse discharges from the bowels. In many instances those attacked have died in a few hours, but the usual course has been about two days, and the termination is generally a fatal one.

It is probable that the usual rains of this season of the year will put an end to the trouble, but further and more accurate details will be awaited with interest.

THE QUARANTINE CONFERENCE IN NEW YORK.

On the 20th of November a conference of sanitary officers was held at the office of the New York Board of Health, at the invitation of Dr. Wm. H. Smith, Health Officer of the Port, to discuss, first, the measures necessary to prevent the introduction of Asiatic cholera at New York and contiguous ports, and, second, the measures necessary to prevent the extension of cholera should it develop in the seaboard cities. Among those present were most of the members of the New York State Board of Health, and represen-

tatives from the health boards of New York, Brooklyn, Boston, Buffalo, and New Haven. Resolutions were passed maintaining that a vigilant quarantine of sanitation at our maritime quarantines *ought* to prevent the introduction of cholera, and setting forth the measures which those present believed necessary to secure a successful quarantine against the disease. As to the prevention of the spread of cholera if once introduced, it was thought that measures to this end must be left to local authorities throughout the country; but a resolution was adopted calling attention to the need of an active sanitary administration on the part of all railroad and other transportation companies concerning the condition of cars, stations, latrines, etc. The chairman was requested to present a copy of the resolutions to the National Conference of the State Boards of Health which is to meet on December 10th, at Washington. Resolutions were also adopted requesting the Legislature to place in the hands of the New York quarantine authorities full powers for meeting the special dangers of the invasion of cholera by such appliances as science has proved to be necessary.

These last resolutions contained a provision that they should be presented to the Governor and Legislature under the authority of the State Board of Health, and at the quarterly meeting of the latter Board, which was held the day following, November 21st, the more fully to carry out the recommendations of the conference, the following was adopted: —

"*Whereas*, The State Board of Health has visited the quarantine buildings in the Lower Bay of New York, and is convinced of the urgent need of repairs, to make them available, if cholera should arrive on vessels entering the port, therefore, be it

"*Resolved*, That this Board recommend to his Excellency the Governor, and the Legislature, such consideration of the resolutions of the conference as will secure the means for the necessary repairs at the earliest possible moment."

MEDICAL NOTES.

— The data obtained by the Anthropometric Committee of the British Association for the Advancement of Science reveal some curious facts respecting the influence of occupation upon physical development. As a rule, the inhabitants of the country are taller and heavier than those of the large towns; London is, however, an exception, and seems to exert an attraction that draws in the more vigorous part of the country population. The police of that city are, as a rule, nearly as tall as the laborers of Galloway — the tallest of Britons — and twelve pounds heavier. The members of the Fire Brigade, who need not be so solid, but are expected to be active, are two and a half inches shorter and twenty-five pounds lighter than the policemen. Athletes average five feet eight and one third inches in height, and only about one hundred and forty-three pounds in weight; from which it is inferred that the majority of the population carry from ten to twenty pounds weight which they would not carry if they were in the highest physical condition. The Fellows of the Royal Society — representing a class of most prominent intellectual gifts — are among the tallest of the race, averaging five feet nine inches and three quarters. Perhaps it is an evidence of nature's allegiance to the supremacy of Law that the criminal class are forty-five pounds lighter than the police and four inches and a half shorter; and they are eighteen pounds lighter and two inches shorter than the average of the population. Lunatics are about as short as the criminals, but heavier. In men of the same occupation belonging to different races the influence of race appears to be predominant over that of occupation.

— The dialects of the respective branches of science are becoming, with the progress of knowledge and of nomenclature, more and more unintelligible to each other. We find, for instance, in an English paper the following sentence from a recently published paper by Sir William Thomson, the eminent physicist: "The stream-lines are as represented in the diagram, in which the region of translational-velocity greater than wave-propagational velocity is separated from the region of translational-velocity less than wave-propagational velocity by a cat's-eye border pattern of elliptic whirls." Mr. Herbert Spencer's famous "Formula of Evolution" is as follows: "Evolution is a change from an indefinite, incoherent, homogeneity to a definite, coherent heterogeneity, through continuous differentiations and integrations." Mr. Kirkman, the mathematician, has rendered this formula into a shape which is, after all, less uncouth (in the true meaning of that word), to wit: "Evolution is a change from a nobowish, untalkaboutable allalikeness to a somehowish, and in-general-talkaboutable not-all-alikeness, by continuous something-elseifications and stick-togetherations."

NEW YORK.

— At the last meeting of the County Medical Society, held November 23d, Dr. S. O. Vanderpoel retired from the presidency after making a brief address, in which he reviewed the work of the past year. The new president, Dr. Daniel Lewis, then made his inaugural address, in the course of which he spoke of the importance of carrying through the suit now pending against the disreputable eclectic medical college, and advocated the establishment of State examining and licensing boards (the latter also to have the power of revoking licenses) for the medical profession. The standing committees for the year were appointed, with Dr. Stephen Smith chairman of the committee on hygiene, Dr. George A. Peters chairman of that on ethics, and Dr. F. R. Sturgis of that on prize essays. Dr. Simon Baruch read a paper on The Management of the Third Stage of Labor.

— At a meeting of the Medico-Legal Society held November 19th a paper on Poisoning by Canned Goods, by Dr. Thomas Stevenson, of London, government analyst, was read. A paper on the same subject which was read by Dr. J. A. Irwin, before the Society recently by Dr. Johnson, of Brooklyn, had attracted his attention, and it was on account of this that he

was led to prepare the one then presented. In it he said that no positive case of acute metal poisoning by canned goods was known in London, and it was reasonably certain that where persons had been injuriously affected by eating canned meats the meat itself was tainted before being canned. In February last, he added, there were in Glasgow several cases of poisoning from tinned provisions, the symptoms being those of gastro-enteritis. An analysis showed salts of tin present, but it could not be proved that the illness was due to the tin. That canned goods usually contained traces of tin had been shown by several British chemists, and was a well established fact, but that such provisions did not usually produce any serious results was a matter of common experience. "I am not prepared to say," he stated in conclusion, "that tin compounds are inert, but evidence is wanting to show that the daily ingestion of fractions of a grain of tin compounds is manifestly injurious to health."

— "The American Society of Public Analysts" was organized at the office of Health Commissioner Raymond, in Brooklyn, on the 24th of November, the principal object of the Society being the dissemination of knowledge relating to the detection of adulteration and falsification of food products and drugs. A committee consisting of Dr. Cyrus Edson, of the New York Board of Health, Dr. E. H. Bartley, of the Brooklyn Board, and Dr. William K. Newtown, reported a form of constitution and by-laws, which was adopted.

— At a meeting of the New York Health Board held November 25th Dr. Cyrus Edson, chief of the Second Sanitary Division, reported that he had seized over fifteen hundred pails of preserved fruits on the ground that they were unfit for human food. He claimed that these fruits, being acid, were liable to attack the metal of the pails, which had loose covers, freely admitting air, and thus become exposed to dangerous contamination. A sample pail was examined by Dr. Waller, analyst to the Board, Inspector Martin, and himself, and the tin plate was found to contain lead. The action of Dr. Edson was indorsed by the Board.

— The Board of Health has been censured by the grand jury for alleged neglect of duty. The foreman reported to Recorder Smyth that in their opinion the storing of manure within the city was dangerous to the public health. It had been shown, it was set forth, that there were many tons of this manure along the East River, between Forty-Sixth and Forty-Seventh Streets, and diseases had been traced to this place as the originating point. In the opinion of the grand jury this was all due to neglect on the part of the Board of Health, which, they understood, was now meditating plans for the abatement of the nuisances. The Board was, however, deserving of censure for permitting such a state of things to exist. It is claimed by some that the Board is not as efficient now under the presidency of General Shaler as it was under that of Dr. Chandler.

— Dr. Charles Carroll Gray, a distinguished retired army surgeon, died at Geneva November 22d. He was educated at Hobart College, Geneva, and also studied medicine at that institution, receiving the degree of M. D. in 1861. In May of the same year he received an appointment as assistant surgeon in the army, and at the battle of Bull Run he was taken prisoner. He was confined successively in the prisons at Richmond, Salisbury, and Charleston, and was exchanged from the latter in 1862. He served throughout the war, and after it was over remained in active service in the army until 1879, when he was retired. His last assignment when on duty was at Fort Riley, Kansas.

— The report of the Committee on Vital Statistics of the State for the year ending September 30th shows that the number of registered deaths was 50,000; unregistered, but reported, 14,000; registered births, 44,000; unregistered, but reported, 24,000; registered marriages, 20,000; unregistered, but reported, 17,000. The average number of deaths per month was about 2200.

PHILADELPHIA.

— Our schools have settled down to their winter's work with classes not quite so large as last year, but they are better equipped, and are apparently doing better work than ever before. Professors Mallett and Osler have been warmly welcomed, and are considered decided accessions to the teaching strength of the two schools.

— A movement is now on foot which may result in good. For several years there has been a strong undercurrent of feeling in the medical profession throughout the State in favor of the establishment of some form of supervision over persons engaged in the practice of medicine, in order to protect both the community and the profession from the unqualified sharks who prey upon the sick. It is reasonable to suppose that the power to grant licenses to practice medicine belongs properly to the State, which cannot certainly evade the responsibility by delegating its duties to the College Faculties. The colleges, however, having enjoyed free trade in doctor-making for a long time, are extremely jealous of having their ancient rights restricted, and when a bill was brought before the Legislature a few years ago to establish a State Board of Health with power to regulate medical practice, the colleges at the last moment came in and quietly crushed it. This was a bitter disappointment to the Committee of the State Medical Society, which had been laboring for years to obtain a State Board of Health, and they naturally blamed the colleges for the defeat, and the result is that we have no Board of Health to this day. Without stopping to discuss who is to blame, we merely give this scrap of history to explain in part the hostile feeling which unfortunately and to some extent unjustly exists between some members of the State Medical Society and the schools.

— As an illustration of the state of public opinion, it is noticed that the County Medical Society and the Medical Jurisprudence Society have each appointed a Committee to confer with a Committee of the State Med-

ical Society with regard to the advisability and feasibility of establishing a State Board of Examiners, which shall be empowered to grant licenses to practice to those found qualified, and to refuse the privilege to those who after examination are found to be incompetent. This Committee has had several meetings and has agreed as to the advisability and necessity of establishing such a Board, all its proceedings to be matters of record, and they are now engaged in discussing whether there shall be one additional for sectarian practitioners, or whether it shall be a mixed Board. One of the most active members of the Committee is Professor Wood of the University of Pennsylvania. It seems very likely that something will be accomplished by this joint Committee, and that a bill will be submitted before our next Legislature. A little, a very little, was gained by the adoption of the Registration Act, but it was a step in the right direction, and we believe that the community is now sufficiently enlightened to take another step. It is now generally known that the value of a medical diploma is chiefly of an æsthetic character, for it is not trustworthy evidence of the skill, professional attainments, moral character, or length of preparation of its possessor. Certainly some other proof of qualification should be demanded besides a stereotyped certificate of doubtful accomplishments, written in a dead language, before an individual may enter upon the serious and responsible duties of the profession of medicine.

— The Medical Jurisprudence Society, which started last January, is growing rapidly, and its meetings are well attended and interesting. At the October meeting Dr. John B. Roberts read a paper entitled Remarks on Legal Control of Medical Practice by a State Examination, which led to the appointment of the Committee just referred to. At the November meeting Dr. Charles K. Mills read a paper on The Case of Joseph Taylor, and Dr. H. C. Wood on The Absurdities of the Law as Illustrated in the Taylor Case. John Taylor was an inmate of the prison who killed his keeper, and who was found guilty by the Court, in spite of the fact that a Medical Commission had pronounced him insane, and suffering from delusional monomania. Weak-minded criminals have a hard time of it since Guiteau was hanged. What is very much needed is a sliding scale of responsibility suited to various degrees of mental unsoundness.

— Professor DaCosta recently exhibited a case at his clinic in which an attack of facial erysipelas was cut short in a remarkable manner by a hypodermic injection of a third of a grain of pilocarpine muriate. The patient received a blow in the face on Wednesday night, and the next morning the upper part of his face was erysipelatous, the inflammation extending rapidly up on the brow and over to the other eye. On Thursday afternoon he received the injection and after profuse sweating the tumidity of the eyelids subsided, and by the next morning he could open both of his eyes. The disease did not return and he became at once convalescent, but took iron for a few days before going home again.

— A curious form of lead poisoning was reported in a case of a woman whose death was investigated by the Coroner last week. The physician who made the examination reported that death was caused by inhalation of the fumes of the white lead paint on old boards which she had been in the habit of using for fuel.

— Dr. Robert H. Alison having resigned the position of Port Physician, it was tendered by the Governor to Professor Bartholow, who declined it; subsequently Dr. Henry Leffmann was appointed.

— On the 18th of November the large addition, built in modern style of Yardleyville freestone, to the German Hospital and out-buildings were presented to the Board of Trustees by John D. Lankenau, Esq., the President of the Board, who at his personal expense had purchased the ground and erected the buildings at a cost of three hundred thousand dollars. A most generous and philanthropic gift.

Correspondence.

COCAINE HYDROCHLORATE IN THE LARYNX.

BOSTON, *December* 1, 1884.

MR. EDITOR, — In the report of the Proceedings of the Society for Medical Improvement published in the JOURNAL of last week I said we had everything to learn in regard to the strength of the solution of cocaine hydrochlorate to be used as a local anæsthetic of the larynx, and also in regard to the best manner of applying it.

I have since tried a twenty per cent. solution (which I learned from recent German papers was the strength used in Schrötter's clinic) on the patient mentioned in the discussion as showing little effect from a four per cent. solution. The result was all that could be desired, sufficient anæsthesia being produced to enable me to reach any part of the larynx without exciting reflex phenomena, which before had been very marked and troublesome.

The solution was applied thoroughly to the larynx by means of a camel's-hair brush, and the anæsthetic effect was almost immediate. The solution was made without acid by adding a few drops of absolute alcohol.

I make this communication to prevent others wasting time with too weak solutions.

Yours respectfully,

FREDERICK I. KNIGHT, M. D.

Miscellany.

PRECAUTIONS AGAINST CHOLERA.

UNDER the above heading President Arthur makes the following discreet recommendations in his recently delivered annual message: —

The pestilence which for the past two years has been raging in the countries of the East recently made its appearance in European ports with which we are in constant communication. The then Secretary of the Treasury, in pursuance of a proclamation of the President, issued certain regulations restricting, and for a time prohibiting, the importation of rags and the admission of the baggage of immigrants and of travelers arriving from infected quarters. Lest this course may

have been without strict warrant of law, I approve the recommendation of the present Secretary, that Congress take action in the premises, and I also recommend the adoption of measures that will be likely to ward off the dreaded epidemic, and lessen its severity in case it should unhappily extend to our shores.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 22, 1884.

Deaths reported 2492: under five years of age, 838; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 596, consumption 386, lung diseases 311, diphtheria and croup 256, typhoid fever 71, scarlet fever 60, diarrhœal diseases 58, malarial fevers 37, measles 34, whooping-cough 29, cerebro-spinal meningitis 14, erysipelas nine, puerperal fever seven, yellow fever one. From *diarrhœal diseases*, New York 22, St. Louis eight, Brooklyn, Chicago, and Boston five each, Cincinnati four, Nashville three, Baltimore and Fall River two each, New Haven and Chelsea one each. From *malarial fevers*, St. Louis 10, New York and Brooklyn seven each, Baltimore five, Chicago three, District of Columbia two, Philadelphia, Nashville, and Charleston one each. From *measles*, New York 16, Cincinnati nine, Brooklyn, Chicago, and Fall River two each, Fitchburg and Boston one each. From *whooping-cough*, New York 12, Philadelphia, Chicago, and Baltimore three each, Brooklyn two, Boston, Cincinnati, District of Columbia, New Haven, Lynn, and Newton one each. From *cerebro-spinal meningitis*, New York six, Chicago three, Philadelphia, Boston, Lowell, Holyoke, and Taunton one each. From *erysipelas*, Philadelphia and Fall River two each, New York, Boston, Baltimore, Cincinnati, and Nashville one each. From *puerperal fever*, New York and St. Louis two each, Brooklyn, Chicago, and Boston one each. From *yellow fever*, New York one.

In 111 cities and towns of Massachusetts, with an estimated population of 1,386,654 (estimated population of the State 1,955,104), the total death-rate for the week was 15.60 against 18.08 and 22.66 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending November 8th, the death-rate was 21.3. Deaths reported 3569: infants under one year of age 899; acute diseases of the respiratory organs (London) 357, scarlet fever 82, measles 79, diarrhœa 73, fever 60, whooping-cough 49, diphtheria 26, small-pox 23. The death-rates ranged from 16.6 in Birkenhead to 31.5 in Preston; Birmingham 18.3; Bradford 21.2; Leeds 25.2; Blackburn 19.8; Leicester 20.8; Liverpool 26.0; London 19.7; Manchester 25.4; Nottingham 25.7; Sheffield 22.4; Sunderland 20.8. In Edinburgh 17.6; Glasgow 25.6; Dublin 25.3.

For the week ending November 1st, in the Swiss cities, there were 17 deaths from consumption, diarrhœal diseases 14, lung diseases 11, diphtheria and croup five, small-pox two, typhoid fever three, measles one, whooping-cough one. The death-rates were, at Geneva 12.2; Zurich 7.9; Basle 12.4; Berne 23.3.

For the week ending November 8th, in the Swiss cities, there were 21 deaths from consumption, lung diseases 14, diarrhœal diseases nine, diphtheria and croup five, whooping-cough five, puerperal fever two, measles one, scarlet fever one. The death-rates were, at Geneva 10.2; Zurich 3.9; Basle 12.4; Berne 31.1.

The meteorological record for the week ending November 22d, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

Date.	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.[1]			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM NOVEMBER 22, 1884, TO NOVEMBER 28, 1884.

McKEE, JAMES C., major and surgeon. Leave of absence extended one month. S. O. 273, A. G. O., November 20, 1884.

GODDARD, C. E., major and surgeon. Assigned to duty at Fort Yates, D. T. S. O. 138, Department of Dakota, November 15, 1884.

LORING, L. Y., captain and assistant surgeon. Assigned to duty, as post surgeon, San Diego Barracks, San Diego, Cal. S. O. 135, Department of California, November 19, 1884.

TAYLOR, A. W., first lieutenant and assistant surgeon. Relieved from duty at Fort Omaha, Neb., and ordered for duty at Fort D. A. Russell, Wyo. Ter. S. O. 101, Department of the Platte, November 19, 1884.

WILSON, GEORGE F., first lieutenant and assistant surgeon. Granted one month's leave of absence from November 20th (Vancouver Barracks, W. T.). S. O. 180, Department of Colorado, November 18, 1884.

WALES, PHILIP G., first lieutenant and assistant surgeon. Now at Fort Cœur d'Alene, Idaho Ter., ordered for temporary duty at Vancouver Barracks, W. T. S. O. 179, Department of Colorado, November 17, 1884.

OBITUARY.

DR. HARVEY L. BYRD died in Baltimore, Md., November 29th, at an advanced age. Dr. Byrd was a native of Georgia. For many years he was a professor in the Medical College of Mobile, but at the breaking out of hostilities in 1861 he joined the Confederate army, and was attached as surgeon to Rylander's battalion of Georgia troops. He served in the army of Northern Virginia, and was thence transferred as post surgeon at Mobile, where he remained until the close of the war. After the war he came to Baltimore, and was one of the originators of the College of Physicians and Surgeons. Subsequently he helped in the organization of the Baltimore Medical College.

SUFFOLK DISTRICT MEDICAL SOCIETY. *Section for Clinical Medicine, Pathology, and Hygiene.* — There will be a meeting of this Section at 19 Boylston Place, on Wednesday, December 10, 1884, at 7.45 P. M. Papers by Dr. J. J. Putnam, Illustrations of Certain Developmental Diseases of the Nervous System, and Dr. P. C. Knapp, Observations on the Cutaneous and Deep Reflexes.

ROBERT T. EDES, M. D., *Chairman.*

GYNÆCOLOGICAL SOCIETY OF BOSTON. — The regular meeting of the Society will be held at the Medical Library Rooms, No. 19 Boylston Place, on the second Thursday of December, at four o'clock, P. M. Papers will be read as follows: Dr. Charles R. Whitcomb, on Cancer of the Uterus, and Dr. M. L. Brown, on The Pathology of Uterine Fibro-Myomata.

H. J. HARRIMAN, M. D., *Assistant Secretary.*

BOOKS AND PAMPHLETS RECEIVED. — A Contribution to the Clinical Study of Rötheln or German Measles. By W. A. Edwards, M. D. (Reprint from the American Journal of the Medical Sciences, October, 1884.)

Address.

CONSERVATIVE PROGRESS.[1]

FIRST ANNUAL ADDRESS TO THE NEW YORK STATE MEDICAL ASSOCIATION, DELIVERED IN NEW YORK, NOVEMBER 18, 1884.

BY HENRY D. DIDAMA, M. D., SYRACUSE, PRESIDENT.

Is not this platform broad enough to afford standing and working room for every one who seeks to know and practice truth?

It is fashionable in certain quarters to decry the medical schools of our country; to censure their practice of so oiling their portals that the grossest ignorance can find an easy and welcome admission; to inveigh against their methods of teaching; and to condemn the facile, if not farcical, examinations which permit incompetence to seize a title and go forth to prey upon community.

Indiscriminate and unmixed reprobation is not only unjust; it defeats its purpose. For whatever may be the deficiencies of our great schools, however far they fall short of what they can and should be, they have excellencies which should not be ignored. They have given to the profession men renowned throughout the world for their wisdom and skill. In their corps of teachers are many whose aptness and industry and ability are unsurpassed. They afford clinical opportunities so rich and varied as to leave nothing to be desired.

If their requirements for entrance and exit have been too low, is it not because the profession have not demanded higher? If the terms have been too short, and the years required too few, and the methods unnatural and deficient, is it not because the profession have given little practical encouragement to the hearty, even if too speedily abandoned, attempts which some of the schools have made to secure needful reform?

Can it be doubted that the accomplished and devoted teachers in the schools are always ready and willing to respond to any earnest call of the profession for a higher standard?

Shall this call be made? Will those who make the demand prove their sincerity by pledging their influence, their aid and comfort, to those schools which, at whatever labor and expense, shall eliminate the faults of the present system and bring it into harmony with the teaching in all institutions of learning, and with the law of mental evolution and growth?

That brilliant results have been achieved under the prevailing system of medical teaching has not been, and cannot be, denied. Would they not have been still more brilliant and satisfactory under a better system?

The native Ceylonese, with instruments which would hardly be tolerated in an American blacksmith's shop, sits on the ground and patiently fabricates jewelry and filigree which are marvels of exquisite delicacy and beauty. Retaining his present artistic taste and skill how much more and better work could he do with the perfected instruments of his civilized brother?

The superiority of the graded system of medical training is not universally acknowledged. At least one prominent teacher and one good medical journal openly profess not simply a contentment with the present unnatural system, but an admiration for it, and a desire to have it conserved. The attempts to reduce chaotic elements to order they denounce as impracticable, and they kindly predict and counsel their early abandonment.

Proposed reforms always provoke some opposition. The attempt to introduce into Mexican farming such modern implements as the steel plow, the cradle, the reaper, and thresher, is earnestly combated by many of the native workers. They not only adhere to the sickle and to the old one-handled Palestine plow, — an iron-shod stick which barely scratches the soil, — and to the threshing floor, where oxen and mules tread out the grain, but they insist that this clumsy system is the better. They hill their corn as our own farmers did fifty years ago. They use a hoe in the operation. But the hoe has no handle, and the native partly creeps and partly jumps, like a kangaroo, from hill to hill, as he goes through the field. Still he loves and reveres the old ancestral implement. He denounces the handle as a device to promote laziness. And he asserts that with a primitive hoe in each hand he can do more and superior work. It was only by compulsion that these earnest Mexican conservatives could be brought to use wheelbarrows on the public works. They preferred to carry their loads of stone and dirt on their backs and heads. And such was their devotion to their ancient method that at first they actually shouldered wheelbarrow, dirt, and all, and then vociferously condemned the new notion as a fraud and nuisance.

Honest differences of opinion should be treated with respect and tenderness. And since these differences exist regarding medical education it may not be unprofitable briefly to compare and contrast the antique system with the modern.

Most of you know from personal experience that in the large majority of medical schools in this country the student, at the very outset, is expected and required to hear lectures on all the branches taught — the most advanced as well as the elementary — every day. Although not usual, the occurrences to be described are by no means impossible. An ingenuous youth, full of zeal, industrious, ambitious, but with scant knowledge of the elements of the most moderate education, is received without question at the grand old conservative college. He matriculates. He attends a lecture on anatomy, — the first he ever heard of this important subject. He is delighted. He enters the laboratory and listens with pleasure and profit to the professor of chemistry. Truly, he says to himself, the ways of wisdom are ways of pleasantness, and all her paths are flowery walks of peace.

He hastens into the surgical department. The lecture is introductory. But in a few days, and while his knowledge of anatomy is still limited to an awful admiration for the suspended skeleton and for the tray of disarticulated bones on the table, the subject of the lecture is aneurism. The bright description, the lucid explanation make the whole subject interesting and satisfactory. The eloquent professor describes the operation for ligating the radial artery in its lower third: "Hold the hand supine; make an incision two inches long on the radial side of the *flexor carpi radialis*. The integument and aponeurosis being laid open the artery is at once brought into view." This is all clear enough to you, learned Fellows, because you have received sufficient anatomical instruction. But the fresh pupil whom we are considering, — one of us perhaps, — whose hopes but a few days ago were radiant and

[1] Concluded from page 531.

towering, becomes perplexed and disheartened, if not disgusted, because he has no knowledge of what radial may mean, whether aponeurosis is an animal or vegetable, or whether the *flexor carpi radialis* be a bone, nerve, or sinew, situated on the crown of the head or sole of the foot.

After the wearisome — wearisome because incomprehensible — incomprehensible because the student has not been prepared to understand it — lecture on surgery is ended, the still plucky pupil ventures into the room where the professor of the art of medicine is showing how insufficiency of the tricuspid valve, by obstructing the onward flow of blood in the *vena cava*, may cause congestion of the portal system, and then gastric catarrh, hæmorrhage, and albuminuria. He does not doubt the truth of the demonstration. But it loses all its beauty and force because the poor fellow has not the slightest notion of what tricuspid, or any other valve, may be, or where the *vena cava* or portal system is located.

In the obstetric department the same failure to comprehend the lecturer results from the same want of preparation. But the rules of the school require attendance on all the lectures. And so, hour after hour every day is wasted, by an earnest and ambitious student, in listening to what he cannot understand, and so neglecting the studies which are prerequisite.

The short winter course is passed, and the student emerges in the early spring with a head full of jumbled and meaningless words, with muddled ideas of medicine, obstetrics, and surgery, and with insufficient knowledge of anatomy, physiology, and chemistry, *because* the time which should have been devoted to these fundamental studies has been frittered away in a dazed attendance on lectures he had never been prepared to understand. The next winter he goes through exactly the same course, but he is now better able to comprehend the teaching.

In *building a dwelling-house* you prepare a plan, — first consulting the good wife regarding the fitness of things, — and then you go ahead decently and in order. You lay the foundations deep and broad and strong. You carry up the superstructure carefully and gradually, so that no cracks nor flaws shall afterwards appear. You put on the roof; finish the rooms honestly, without veneer or graining, and wait a sufficient time before you move in with your family. You do not jumble all together, working an hour on the turret, another on the trench for the cellar walls, and still another on window sills and hard finish and joists and rafters.

If you were to *train for an athlete* you would not unwisely overstrain your sinews the first day by doing work beyond your ability. You would begin with light weights and moderate walks, increasing the labor each day as the muscles became developed and strong.

If it should be proposed to *evolve a mathematician* out of raw material we would not ask the candidate the first day to solve the problem of the hare and hounds, nor to listen to a demonstration of the twelfth Proposition of Euclid. We would begin with the simplest examples in addition and subtraction, and then advance through the higher and still higher departments, till at length, like Verrier, the fully-developed candidate could discover and locate a planet by pure mathematical calculation.

In *training a child* to be a *linguist* we begin with the simplest form of speech and lead him on, by precept and example, till he can speak with the tongues of men and of angels, and have charity besides. It would be unnatural, and therefore unwise, to allow him to waste time at the start in listening to the sounding brass of Cicero's orations, or the tinkling cymbals of Xenophon's fables.

If in every other department of human industry the natural development plan is pursued without opposition or question, why should medical education be the marked exception? Why, if we wish, as we ought, to *utilize* to the utmost *the time and talents* of a *medical student*, should we not take him step by step — for that is what the graded course means — through Anatomy and Physiology, Histology and Chemistry up to Surgery and Practice and Obstetrics? Why should we have him fritter away the scant but precious hours of his first course of lectures in listening to what he cannot by any possibility fully comprehend? Would not this be doing what ought not to be done, and leaving undone what ought be done?

The natural system of medical education is no longer a beautiful and dreamy speculation. It has been fairly tested, and it has been found efficient. Those who know it best give it the heartiest approval. The requirements for matriculation are, or should be, more and more exacting every year. The written and oral examinations are frequent and thorough. The yearly and final ordeals are very trying and severe; but the students who have brains, application, and faithfulness always come through triumphantly. Even those whose natural capacity is not the greatest succeed remarkably. Under a natural system their mental growth is rapid and astonishing. At the last they seldom fail because their time has been husbanded and properly employed; because their studies have been interesting and delightful inasmuch as they have been thoroughly comprehended and mastered every step of the way.

Here are two pictures. Do they not represent the prominent differences in requirements and results between the ancient, but still prevailing system, and the modern one?

In one case: No preliminary examination; only two short courses of lectures required, the second identical with the first; the novice required to attend lectures on every subject every day, neglecting preliminary work because the time which might have been devoted to it has been worse than wasted in hearing learned talk which he was not prepared to understand; valuable clinical and laboratory opportunities; no examinations to advance to higher grades, for there are no grades; a final examination which is so superficial in many instances as to be little better than a farce, and whose meshes are large enough to let mediocrity and inferiority, as well as the superiority, which is always present, pass through with greatest ease.

In the other case: Preliminary examinations which require a certain, even if insufficient, preparation; three years of training at the college, the novice beginning at the beginning; all his time employed in hearing and doing what he can and should understand; his capability and progress tested by frequent oral and written examinations; his advance from grade to grade checked if his fitness be not established; valuable clinical and laboratory opportunities; searching yearly examinations; and a final examination, which, although of great severity, does not, except in rare instances, result in rejection, because the student has been educated in a way which accords with nature and does not violate it.

And yet the difference between the old system and the new is greatly one of arrangement. A change from one to the other can be effected with as little commotion as was noticed when twenty discordant and puzzling computations were consolidated into the present admirable system of standard time.

No more teachers would be required; no better lectures could be delivered, or would be needed. The labors of the professors would be considerably increased because the total length of the lecture season would be more than doubled, but they would hardly be conscious that a radical change, amounting to a revolution, had taken place. But the students, who are to be the physicians of the future, and the confiding patients of these physicians, would derive incalculable benefit.

Would not the adoption, by all the schools of this country, certainly by those of this State, and especially by the three prominent ones in this medical metropolis, of the natural system with the honest and vigorous enforcements of its entire demands, secure a practical elevation of the medical standard, so much yearned for, deserve the support of the profession, and restore a confidence which has been seriously impaired? Would not this adoption protect the community to the greatest extent possible from incompetence, and render unnecessary, so far as legitimate medicine is concerned, — the only medicine about which we have any solicitude, — the proposed State Board of incongruous Medical Examiners?

Original Articles.

NOTES ON NASSAU AS A WINTER RESORT.

BY HAMILTON OSGOOD, M. D.

Physicians of our Northern States are frequently puzzled as to where to send such patients as are unable to bear a northern winter. Many of the winter resorts in our Southern States are situated upon our Atlantic seaboard, or at any rate are exposed to sudden fall of temperature, and therefore are not entirely suitable for the very delicate. But we have one spot which is free from the latter objection. The town of Nassau, on New Providence Island, one of the Bahamas, has a climate whose temperature in winter is marvelously steady, and for such cases as may be safely sent there Nassau possesses advantages which can be found nowhere else in the vicinity of our country, and very rarely, and perhaps with only two or three exceptions, in the Eastern hemisphere.

Moreover, Nassau lies near at hand. One of the swift sailing steamers — the Cienfuegos and the Santiago — leaves Pier 16 or 17, East River, New York, every other Thursday during the winter. The agents of this line of steamers, J. E. Ward & Co., 113 Wall Street, are prompt and courteous. Leve & Alden, Washington Street, near the Old South Church, are their Boston agents.

These steamers are luxurious in every respect. The Cunard line never gave its passengers such a bill of fare, nor food so excellently prepared, as may be found on these Nassau steamers, and whoever falls into the hands of Chief Steward Petersen of the Cienfuegos will discover a steward who is kind to his passengers, especially invalids, not because he expects a fee (he is a *rara avis*, inasmuch as he refuses fees) but because he *will* make them comfortable, and if a lady desires a quail on toast or broiled oysters at nine P. M. she can have either. I emphasize this matter because it is important. Those who go to Nassau are usually delicate, and the physicians who send them will be glad to know that the ocean trip will be as comfortable as luxuries can make it. Moreover, such is the gentlemanly care extended to passengers by the stewards, that if a lady were left safely on board one of these steamers in New York, I should deem it perfectly feasible for her to make the trip alone if necessity urged it.

The fare to Nassau is fifty dollars. The trip occupies sixty to seventy hours. You leave New York deep in snow and ice on Thursday P. M. On Sunday you are looking upon the luxuriant tropical verdure of Nassau and are eager to exchange winter garments for a summer dress. At this season the passage commonly is quiet and free from severe weather. The hurricanes and dangerous storms to which the Southern Atlantic Islands are often subjected confine themselves to the months between April and October.

Reaching Nassau, the passenger encounters the one disagreeable feature of the trip. It is impossible for the steamers of the Ward line to cross the bar into the harbor. Passengers, therefore, are transferred outside of Hog Island (a long, low, green breakwater which nearly incloses the lovely sheet of water lying between itself and Nassau proper) into a filthy schooner, reeking with the smell of bilge water, and too well known as the Dart. If she were called the Dirt, there would be a satisfactory fitness in the name. It is no joke for a delicate lady to walk down a steeply inclined plank into this tender, which, probably, is flying up and down in a chop sea. Once on board, however, the trip to land is made within thirty minutes. *But*, — and this is truly a terrible alternative, — *but*, if the wind blow strongly from the north, no such transfer can be made at this anchorage. The steamer proceeds to South West Bay, on the other side of the island, and there in quiet waters removes her passengers to the dirty Dart, which is obliged to beat all the way to Nassau, sometimes occupying ten hours before reaching the town. The effect of this prolonged transfer upon invalids, without food or shelter, need not be described. When I left Nassau the steamer agent at that place had just begun to send carriages across the island to meet passengers whenever the steamer was forced to go to South West Bay. In that case they were set ashore in row boats. Still, this method involves a drive of about sixteen miles, and sometimes it must be taken after dark. It would be well in writing for rooms by a preceding steamer to request Mr. Morton of the hotel to send a carriage to meet the steamer in case she be obliged to go to South West Bay. A passenger could in any case be set ashore in a row boat in order to take the carriage.

When I left Nassau something was being done in the direction of cutting a channel across the bar in order to allow vessels drawing over fifteen feet to enter the harbor. If America owned Nassau this would have been done years ago. But Nassau, in so far as improvements are concerned, is the quintessence of Sleepy Hollow, and its rulers are mostly sleepy fellows.

Once in sight of the place, you see a town straggling picturesquely along a low shore, made tropical by groups of banana and cocoa-nut, almond, palm, and other trees of the latitude, and climbing gradually

away from the harbor until it reaches a height of 230 feet, and there it stops, for the island goes no higher. Landing at the wharf you may walk in five minutes to the hotel if you choose, taking your left along Bay Street to Parliament Street and so up to the gates of the Royal Victoria Hotel, a large building of limestone, set in an outer frame-work of balconies and large posts — the house being white, the wood-work red. This is a surprisingly well-kept house, and Mr. Morton, the obliging and courteous host, understands his business. When one considers that all meats and ice, oysters and game, and wines, and many vegetables must come from New York, the table, which is well served and liberally supplied, seems remarkable. The house is absolutely clean. Scrubbing never ceases. Rates of living vary from $1.50 to $3 per day, according to location. Well water in Nassau is unsafe for drinking purposes. The water used for drinking at the hotel is rain water stored in a cistern, and seemed perfectly pure. There are no water-closets or fixed wash-basins in the hotel proper. The outlook from the northern side over quaint houses and profuse verdure upon the beautiful harbor is very charming. The favorite rooms are upon this side of the house, but inasmuch as the sun never touches this front, I should advise invalids to choose southern rooms. They are a little warmer during the day, but they have the medicinal benefit of sunshine. Inmates can occupy the balconies on the northern front during the day if so inclined. Write for rooms in the eastern and southeastern end of the house. Rooms facing directly south are a little noisy in early morning hours. Attached to the hotel is an old building formerly used, and now known as a "College Building." In this house the three rooms on the upper and *western* side are the best and quietest of all.

The dews of Nassau are phenomenally heavy. This is another reason for choosing southern rooms. The northern apartments are much damper. It is not safe for invalids to be out of doors after five o'clock P. M., and nine o'clock in the morning is quite early enough for out-of-door plans. During the winter rains are infrequent and the sun an almost constant companion. When one first experiences Nassau weather it seems oppressively warm, and the temptation is to leave windows open at night. It is safer, however, to close all windows at six P. M., and wait until equilibrium between the temperature of the earth and air has become somewhat established before opening them again, and then only one should be raised, and that merely a few inches. The dampness of the night air in Nassau is often a serious matter to patients who are subject to rheumatism or neuralgia. It disappears quickly after sunrise, for the island is composed of very porous limestone, and together with the heat of the sun very soon disposes of moisture. After four P. M. invalids will do wrong to *sit* out of doors. They may walk until five o'clock on sunny days.

As to amusements: There are delightful walks and drives in various directions. The roads are smooth and solid. Saddle ponies at seventy-five cents the hour are numerous, and one may ride daily at even lower rates. For driving, a carriage and man may be engaged for two hours daily at a cost of six to eight dollars per week. The horses are small but able. Space will not permit a description of the very beautiful though quiet scenery of the island and of its objects of interest. For those who are able shooting repays all trouble. Fish are remarkably plenty, and of such great variety that they have never been classified. Fishing, therefore, is a favorite sport, and by sailing a few miles out you may catch noble sea-bass and be seriously plagued at the same time by sharks. The lesser fish have received most comical names. At breakfast you eat "Hamlet," "Dauphin," "Cock-eye," "Grunt," "Nurse," "Pilot," "Miss Nix," or "Schoolmaster." To eat a *filet* of *fried schoolmaster*, by the bye, gives one a sense of compensative justice, even though school days *be* far in the dim past. Sailing is another enjoyment, and there was never more perfect opportunity nor finer waters. There are several good and fast boats managed by negroes who are thoroughly competent. Engage Capt. Billy Major, and you will have his new boat and a most companionable skipper. The "Sea-Gardens," the "Sea-Windows," the "Coral Reefs," and the islands are the favorite objects of a water trip. The exquisite sea-fans, coral, "Angel," and "Rainbow" fish are vividly seen at the Gardens, and a black fellow will bring up any fan or coral or sponge you may point out.

Near the hotel, in an octagonal building, once used as a prison, and formerly occupied many a time by private prisoners (for Nassau was once the favorite rendezvous of the notorious Blackbeard), is a well-chosen circulating library of 6000 volumes. Fifty cents per month allows one to take out five volumes daily. There is a sightly church devoted to the English service. Churches of every denomination are numerous among the blacks, who are steady church-goers. Shops are plenty. There is one good apothecary shop, the "Nassau Dispensary." In another I asked the proprietor where he obtained his alkaloids. A look of blank stupidity was the reply I received. He had never before heard the word. There are 16,000 inhabitants, of which, perhaps, 300 are whites, the remainder, naturally, are negroes, and mostly of the happy-go-lucky order, who think themselves equal, if not superior, to the whites. The men and boys beg for coppers on all occasions, and for no reason. Women and girls never do. But all are civil and good-natured. The soldiers of the garrison are black, their officers white.

It is claimed that the climate of Nassau is not debilitating. This is untrue. Many over-enthusiastic articles upon Nassau have been and will continue to be written. Many individuals, the greater number of visitors, indeed, find the air debilitating, especially during the early days of their stay. Ocean breezes are very nearly constant, but they are warm and moist. The temperature is remarkably uniform. I saw the mercury at 65° F. I saw it once only at 80° F. But during nine days out of ten, between December and March, it varies between 70° F. and 75° F., until one begins to disbelieve the thermometer. During my stay of two months I kept careful record of the thermometer, the average being, at nine A. M., $71\frac{9}{10}$° F.; at 1.30 P. M., $73\frac{1}{2}$° F.; at 6.30 P. M., $71\frac{3}{4}$° F. Barometer averages a pressure of 30′ throughout the winter.

Observation convinced me that phthisis in the early stages will improve in this climate *if*, let it be noted, patients are careful in regard to their hours out of doors. It is claimed that this disease rarely or never originates in Nassau, excepting among the blacks, and they average only four cases in 1000. I think it would be as unfair and as hopeless to send a patient in the advanced stages of consumption to Nassau as to send him elsewhere. Heart disease ought to improve here.

Neuralgic and rheumatic patients who were at Nassau last winter cursed the day of their coming and their doctors for sending them there. On the contrary, I met others who, notwithstanding they suffered last winter, had been there every winter for years, and will continue to go. Of course every case, whether of rheumatism or consumption, is largely a law unto itself, and this explains why one case thrives and another does not. Much depends upon a clear understanding of his patient's peculiarities before a physician sends him to this or any other winter resort. According to Dr. Kirkwood, a resident physician of forty years' observation, "consumption invariably finds relief in Nassau." A few grains of salt were well applied to this statement. Incipient phthisis would, probably, improve or be arrested. Likewise, but with less certainty, phthisis in the second stage. Consideration, however, should be given to the ability of a given case to live in sea air which is more or less charged with moisture. Invalids have strong idiosyncrasies in regard to sea air. It stimulates some; others are depressed by it. Here, again, the physician should know whether his patient can bear such an atmosphere. Bronchial catarrh, according to my experience, improves in salt air, and, therefore, at Nassau. Still it must be remembered that Nassau debilitates a large percentage of invalids who go there. But after leaving the island they find they have gained in strength. The climate continues its good effects weeks after it has been left behind. Syphilis, even of the slightest degree, does very badly in this climate, and progresses rapidly. In one case which I treated while there the disease, supposed to have disappeared fifteen years before, made its appearance in the long bones. Hip-joint cases and rachitis improve in Nassau.

Malaria and remittent fever abound during the summer, and in some localities during the winter, especially if the wind blow from the south. The latter is sometimes so intense that it suggests yellow fever, a few cases of which sometimes occur in summer. Leprosy exists, and there is a special hospital for lepers.

Cases of nervous prostration find the Nassau climate extremely favorable, far more so than any of our American winter resorts.

Liver affections do fairly well, and I observed steady improvement in a serious case of nephritis.

Visitors must not expect to be able to keep up their milk diet in Nassau. Milk is very scarce and very poor when obtained. I discovered that several physicians had ordered patients who were in Nassau to live on milk. This simply shows what, unfortunately, I observed in many instances during my stay here and elsewhere, that physicians send their patients away from home without being properly familiar with the details of the places to which they send them. This, confessedly, is a two-edged sword which cuts both ways. It injures the physician. It infuriates the patient. A physician can easily procure all details from resident physicians in any resort. But, naturally, the reports given by such resident medical men are apt to present the golden side of the shield. This must not be forgotten. *Cum grano salis* these reports are useful. Frederick Corbett, a colored man who lives at Mackie's Corner, will supply a limited amount of honest milk at twenty cents per quart. He is not generally known, and should be engaged *sub rosa*. Cow's milk at the hotel is an extra at twenty-five cents per quart, and is poor. Condensed milk is used at table. Gentlemen have been known to send cows to Nassau for the use of wife or daughter. This is useless. There is no pasturage on the island.

The best resident physician in Nassau is Dr. W. G. Maclure. His house overlooks the hotel grounds. Educated in the University of Pennsylvania, in Dublin, and in London, he is able, and familiar with all the modern means of diagnosis and treatment. Moreover, he is a very agreeable gentleman. Dr. Kirkwood has retired from practice.

Visitors may carry with them a letter of credit, American paper or gold, or their check-book. Mr. Morton requires American currency in payment of hotel bills. American drafts are worth a premium at Mr. Lord's banking-house, next the post office. Request him to provide you with American gold, and give him three days' notice and for your check or a draft on your letter of credit he will pay the face value in American gold, and give you two or three per cent. premium besides. You lose this percentage at the hotel. The currency in use at Nassau is English silver and copper. English gold is never seen.

I had nearly forgotten to suggest that invalids who visit Nassau will improve more rapidly if they are advised to remain *indoors* for two or three days after their arrival; venture upon the balcony for only an hour or two during the next three days, and thus gradually become acclimated. Invalids should be made to understand that their first two weeks in Nassau climate may disappoint and discourage them, for the debilitating effects of the atmosphere are very exhausting at first. They should be patient and wait until they have become accustomed to the climate. From that moment they begin to improve.

There are three or four boarding-houses in Nassau. The largest, near the hotel, is said to be satisfactory. The rooms in the hotel on the third floor are much quieter than those on the story below, and more favorable for chest cases, because farther from the ground, which is always damp at night. Delicate cases should wear thin undergarments at night. There are no sudden changes of temperature, but the sensitive feel the effect of dews, which are far more profuse than one would easily believe until he had seen them.

Once or twice during the month of March, in case a sufficient number of passengers wish to go that way, Ward & Co. are willing to run their steamers, on the homeward trip, into Savannah. The fare is then the same as if one went on to New York. Otherwise visitors are obliged to reach the States by the way of Cuba, and occupy two weeks in doing so. Of course no invalid would think of going directly to New York in March, which is the month of exodus from Nassau. In my own case, not wishing my invalids to go through Cuba, I chartered a new three-masted schooner which came into the port, provided the necessary eggs, chickens, milk, beef, and fruit, and not only enjoyed a delightful run to Key West, where we were taken off by a pilot boat, but I saved at least one half the ordinary cost of going *viâ* Cuba. The captain gave up his cabin to my party, and took us across in forty-eight hours for $150. I then paid the pilot boat twenty dollars for setting us ashore. In making this arrangement it is necessary to be sure of having a *clean* schooner. Beware of old coasting vessels.

I trust my notes will be of use to physicians. They might be much more extended, but I think I have given all the necessary points, many of which would

have been valuable to me if I could have obtained them before I went to Nassau. Invalids usually begin to go to this resort in December, the majority setting out after the 15th of the month. The hotel is closed by April 30th. Invalids begin to leave the port on the 1st of March. It is well to engage rooms by the mail preceding the departure of visitors. Address Mr. Morton, Royal Victoria Hotel, Nassau, N. P., Bahamas. He is very obliging in making any change of rooms which may be desired by his guests. No telegraphic communication exists between Nassau and the main land. Mails arrive and depart twice monthly.

CASE OF HYSTERICAL HEMIANÆSTHESIA, CONVULSIONS, AND MOTOR PARALYSIS, BROUGHT ON BY A FALL.[1]

BY G. L. WALTON, M. D.

Assistant to the Department for Diseases of the Nervous System, Massachusetts General Hospital.

IT has been long known that hysteria may be brought on by trauma both in persons predisposed to functional nervous disease, and in those possessing no such tendency. The subject has acquired a special interest of late through its medico-legal bearing, and many cases are on record in which this variety of nervous disturbance has formed the basis of claims for damages after railway accident.

Attention has been recently called[2] to the importance of searching carefully for hemianæsthesia in cases of vague nervous injury following railway collision or other shock, in that this symptom is apt to persist after others have passed away, and because when found it furnishes a sign of real functional cerebral disorder whose simulation in all its details would be extremely improbable as well as difficult. This point is of the greatest practical value on account of the peculiar difficulties surrounding the investigation of this class of cases. Even in a case of simple hysteria, without apparent ground for deception, the difficulties are often great in the way of deciding just how much of the clinical picture before us is genuine, and how much is due to conscious or unconscious simulation. How much harder must this question become when thousands of dollars hang in the balance. This factor should put us especially on our guard, but on the other hand it should not be allowed to lead our skepticism too far and cause us to include in our suspicions the innocent with the guilty. The chief value of such cases as the following lies in the fact that no claim for damages exists, so that the chances for malingering pure and simple are greatly reduced, and we have an opportunity to see how a severe and lasting functional disorder may be brought on in one person by an accident which in another might give rise only to passing mechanical injuries. Our patient possesses evidently by inheritance a marked neurotic tendency. Enough cases of traumatic hysterical hemianæsthesia have been published occurring in persons possessing no such taint to show that this is by no means a necessary factor.

The name *hysterical* is perhaps unfortunate as applied to these cases, inasmuch as a certain degree of opprobrium is suggested by the word hysteria, which these cases hardly deserve, where there is a real cerebral disturbance, the exact nature of which, to be sure, we do not yet understand, but whose existence we cannot doubt, and whose symptoms we can study and classify with as much accuracy as those of any other disease. The word *functional* is perhaps preferable, in that it expresses the condition without carrying with it misleading associations.

CASE. The patient, Miss H., American, aged twenty-nine years, has been under treatment in the Nervous Out-Patient Department of the Massachusetts General Hospital for about nine months, having entered with the following history: She belongs to a family of neurotic tendency. Her mother is an extremely nervous woman. Her brother suffers from chronic rheumatic disease, affecting at present the vertebral articulations. Her father is said to have suffered from a similar complaint. There is no history of insanity in the family. She herself was always well and strong, with the exception of general nervousness and recurring sick headaches, until six years ago, when she fell down the cellar stairs, receiving severe bruises upon the back and abdomen. The accident was followed by unconsciousness lasting one week, and by confinement to bed for four and a half years. During this time she suffered from continuous pains in the back and right side, including the head, trunk, and extremities, for which she inhaled ether for some months, and afterwards took much morphia. For varying periods during this time she lost all power of motion on the right side. Sensation on the right side was wanting most of the time. Cramps, convulsions, and vomiting were frequent. The general condition gradually improved, and the motor paralysis lessened, becoming complete only at intervals. Pain in the back persisted, together with pain in the hypogastric region and difficulty in passing urine.

Physical examination on admission. Patient is a well-nourished woman, of fair intelligence and emotional tendency. All movements are slow and somewhat awkward on account, the patient says, of pain in the back. The tendon reflex is greatly exaggerated, the lightest tap causing a twitch of the whole body. The pupils are alike and react normally to light. There is great sensitiveness to pressure over the lower cervical and middle dorsal vertebræ, also at various spots on the scalp. Considerable loss of power exists in all muscles of the right side, and there is diminution of all varieties of sensation on the right side to the median line. Only heavy pressure is perceived at all on this side, and neither pricking, pinching, nor the strong faradic current causes pain. The prick of a pin draws no blood on the right. The patient is unable to distinguish movements of the elbow, wrist, or shoulder-joints with the eyes shut.

There is entire loss of *hearing* by the bone on the right, and the hearing through the air is greatly impaired, the medium voice being heard only in the immediate vicinity. High tones (tested by Blake's method) are heard up to 30,000 vibrations on the right, to 35,000 on the left. The hearing on the left is normal by bone and air. There is entire loss of the senses of *smell* and *taste* on the right. *Vision* is normal on the left. On the right all responses are slow, the visual field is retracted almost to central, amblyopia exists even for central vision, and colors are distinguished with difficulty. Long-continued effort on the part of

[1] Read before the Suffolk District Medical Society, October 25, 1884.

[2] Putnam, Boston Medical and Surgical Journal, September 6, 1884.

the patient brings the vision of the right eye gradually up to normal (a fact which alone establishes the functional nature of the anæsthesia). The optic disks are normal. No abnormality is found in the organs of reproduction.

On three different occasions within the first month of treatment at the hospital the patient presented herself with a history that no urine had been passed for two days. The catheter was passed each time, once with no result, once drawing about an ounce of rather high-colored urine, once drawing sixteen to twenty ounces of pale, clear urine of 1006 specific gravity. The patient complained each time of distressing desire to micturate but inability to do so. On another occasion the catheter, though urgently requested by the patient, was refused, external examination showing no marked distention of the bladder. The refusal was reported to have been followed by persistent vomiting, and the patient was from this time allowed catheterization whenever desired, the operation being, however, always performed by a female nurse. The difficulty persisting, the patient was taught to pass the catheter herself, which she does still several times a week.

On one visit a fairly strong faradic current was applied with one electrode in the bladder and the other on the hand. This brought on a state of tonic rigidity lasting an hour, and was therefore given up, although the patient reported a decided relief of bladder symptoms for some days after.

The convulsion produced by this operation has been many times repeated at the hospital, and is said to be of frequent occurrence at home, being brought on sometimes by mental or physical shock, but generally occurring spontaneously. At the hospital the convulsions have followed catheterization (whether performed by a doctor or by a female nurse), as well as the application of electricity, and have also come on with no apparent stimulus, mental or physical. In these attacks the patient grows gradually rigid, sometimes inclining to the right until extreme pleurothotonos is reached, and again passing in the same way into equally extreme opisthotonos. At times the patient passes gradually from one of these positions to the other. No clonic spasms or emotional attitudes appear. There is no sign of consciousness, and between the attacks the patient says that she knows nothing about them excepting that she feels their approach, and that she is very lame and sore afterwards, especially on the right side. The duration of the rigidity varies from half an hour to several hours. The inhalation of ether has only a temporary effect. The subcutaneous injection of apomorphia (one twentieth of a grain) produced on one occasion relaxation of the spasm with nausea and retching; on a second trial the same dose proved inefficacious. Pressure over the ovarian region on the right side during the convulsions is generally followed by relaxation of the spasm.

On two occasions the patient has presented herself with œdematous swelling of the right ankle and wrist, without redness, sensitiveness, or special discomfort on motion. No evidence of cardiac or renal trouble was found, and the swelling passed off each time in a few days without treatment.

About five months after her first appearance she suddenly lost the use of the right arm completely, and the paralysis has persisted up to the present time.

The patient being encouraged to attempt rhythmic movements of both wrists, concentrating the will upon the right while restraining the excursion of the left, gradually regains mobility of the paralyzed member, another demonstration, hardly needed, of the functional character of the paralysis.

The patient's general condition has gradually improved, the pains are now less severe without morphia than they formerly were with it, although the drug was not given up without a hard struggle. The bladder symptoms are less distressing, the patient looks brighter and feels better. The hemianæsthesia persists. The convulsive attacks are much less frequent.

DOUBLE INGUINAL HERNIA IN A MALE INFANT THIRTY-EIGHT DAYS OLD — STRANGULATION ON THE LEFT SIDE — HERNIOTOMY.[1]

BY L. W. STEINBACH, M. D.,

Adjunct Professor of Anatomy and Surgery in the Philadelphia Polyclinic.

The subject of my remarks, a male infant, was born on September 2d of the present year, at the beginning of the ninth month of utero-gestation. During six weeks preceding labor the mother was confined to her bed or room on account of hæmorrhages, due to partial placenta prævia. The infant was feeble and bore evidence of premature birth by its general debility, rather than by any specific sign of incomplete development. I estimated its weight at about five pounds. Within two days the child became jaundiced, but his condition otherwise, as well as that of the mother, was sufficiently favorable for me to cease paying regular visits after the tenth day.

On the morning of October 11th the father called and requested me to see the child, because it had been unusually restless during the night, and because the mother had noticed a swelling in the groin the previous evening.

Thinking that this swelling, as described to me by the father, might be a rupture, I visited the child without delay, and on rapid inspection found a deeply jaundiced little patient, not markedly increased in size since birth, with a tumor in each inguinal region, so that the pubic region resembled a mons veneris, with the adipose tissue well developed. As this, however, was not likely to be the case in so poorly nourished an infant, I continued my examination by manual palpation, and felt on each side a firm swelling, which reached up to the respective external inguinal ring, and extended obliquely downwards and inwards into the scrotum to the extent of more than two inches. The tumors were hard, and only slightly elastic, but in neither one could I locate the testicle or separate it from the rest of the tumor.

It will appear that the diagnosis must have been easily arrived at, because there are but few pathological conditions likely to be found in an infant that would resemble this, other than hernia, or perhaps hydrocele. Yet, fearing to exert pressure upon such tender structures in order to satisfactorily outline the testicles, I entertained some doubt whether I was really dealing with a case of double inguinal hernia, for which there existed the speculative causes of congenital debility, a patulous canal, and above these an impediment to the easy evacuation of the bladder in the existence of phymosis.

[1] Read before the Philadelphia County Medical Society, November 19, 1884.

I informed the parents that I believed the child to be suffering with a double hernia, and that I would make an attempt to reduce it.

The amount of manipulation which I considered to be safe not having lessened the size of either tumor, and there being no urgent symptoms, I left with the promise to return towards evening of the same day, with instructions to the mother to note carefully whether the child urinated or had a fæcal evacuation. At my evening visit I learned that the child had had no passage since the preceding day, that it passed but a small amount of urine, and was disinclined to nurse. I now renewed my attempts at reduction, and succeeded in returning the protrusion on the right side into the abdominal cavity, the testicle remaining in the scrotum. Only at this juncture did I become positive of my diagnosis. My exertions to reduce the tumor on the left side proved unavailing. In order to ascertain whether I could induce an evacuation of the bowels without endangering the child's condition I inserted a small cone of soap into the rectun. This met with prompt response from that organ, and together with the soap a small amount of inspissated mucus, intermixed with or, rather, discolored by fæcal matter, was expelled. This convinced me that a constriction existed somewhere in the intestinal tract. Placing a small compress over the right external inguinal ring, and securing it by a bandage, in order, if possible, to prevent a recurrence of hernia on that side by straining in the act of micturition, I left my patient.

In the morning and again towards evening of the following day attempts made at taxis were unsuccessful. Constipation, scanty urination, and refusal to take the breast continued until the third day, when I consulted with Dr. John B. Roberts, who concurred in the diagnosis of strangulated hernia.

After some manipulation, which somewhat reduced the tumor in size and seemed to relieve the symptoms, it was agreed to postpone operative procedure until more urgently required. Towards evening of the same day the vomiting which had existed before became more pronounced, and the copiously-emitted substance in its consistency, color, and odor resembled fæcal matter.

About noon of October 14th, and therefore the fifth day after the symptoms of hernia were first noticed, and when the child was just six weeks old, an anæsthetic (ether) was administered, and the last, but unsuccessful, attempt at reduction having been made, I proceeded, with the material aid of Drs. Roberts, O'Hara, and other gentlemen, to perform herniotomy.

Making an extensive incision through the tegumentary structures and subsequently dividing two additional layers of investment to the hernia, a sac was reached, which was hard to the touch, and distended by fluid contents. A puncture of this sac and evacuation of its sero-sanguinolent contents by means of a hypodermic syringe caused its partial collapse, and a trial was made to return the protrusion into the abdominal cavity. This attempt proving ineffectual the hernial sac was incised. This laid open to view a coil of small intestine of a purplish-red hue, and below it the testicle and the epididymis. This last peritoneal investment was the tunica vaginalis testis, and consequently formed the true hernial sac.

Even now an obstacle to the return of the intestine presented itself at the constricted neck of the sac. The tender age of the patient and the delicate and small structures involved necessitated the employment of the ophthalmic surgeon's canaliculus knife, in place of a Cooper's hernia bistoury, whilst a small grooved director served the purpose of a hernia director until an incision enlarged the opening to a sufficient extent to permit of the insertion of Levis's hernia director. The hernia was of the oblique variety, and after extensive enlargement of the external inguinal ring over Levis's director the intestine was returned into the abdominal cavity.

The interrupted wire suture was now employed; the first and second stitches penetrating all structures from without into the abdominal cavity, approximated the edges of the external abdominal ring. A strip of rubber tubing was inserted, to favor drainage. The loss of blood was insignificant in amount. Antiseptic precautions were observed, by using a solution of corrosive sublimate for the hands, sponges, and towels. whilst the instruments were kept immersed in carbolized water. An existing phymosis, which was regarded a factor in the production of the herniæ, was corrected at the same time.

A few hours after the operation the child had a normal passage; the urine which was voided contained a dark-green sediment, which remained as stains on the napkin. The child took the breast readily, and appeared in no way to be disturbed by the operation. Primary union took place throughout the extent of the wound, and the drainage-tube was removed on the third day, after which the small orifice thus left also closed. No symptoms of peritonitis, or inflammation elsewhere, appeared; the pulse was better than before the herniotomy; the excretions continued regular, and everything gave promise of a favorable result except that the babe did not gain strength, and the jaundice became rather more pronounced. On the fifth day after the operation the child died, and I have good reason to believe the cause of death lay elsewhere than in the the herniæ.

Not the rarity of the affection induces me to present this case to your attention, but rather my belief in the propriety of performing the operation even in so young an infant. I am not conversant with the literature of the subject, and do not know whether a few or many cases are recorded, but my observations of this one case causes me to make the deduction that the operation should be performed unhesitatingly whenever indications for it exist; and I believe that the more rapid reparative process existing in infancy gives an even more favorable prognosis than the same operation performed on the adult.

Reports of Societies.

PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

C. M. GREEN, M. D., SECRETARY.

OCTOBER 25, 1884. The President, DR. JAMES C. WHITE, in the chair.

DR. AMORY read a paper on

THE MANUFACTURE OF OIL OF CADE,

and in this paper mentioned the fact that Dioscorides used this medicinal agent in his time. Since then its periods of use have been inconstant, until Hebra re-

vived its use about the year 1865. Dr. Amory visited the sections in Southern France where it is chiefly manufactured, and stated that the oil of cade is a mixed tarry product from the distillation *per descensum* from the roasting in crude earth ovens of all parts, but chiefly the dry wood, of the *Juniperus oxycedrus*, which grows in the Department of the Var among the hills and distant from the towns and cities of Southern France, namely, Toulon, Marseilles, and Nimes. The oil or tar is sold just as it is delivered by the peasants, and without purification. Its chief distributing depot is Nimes, near which place it has been used for years as a sheep wash to get rid of sheep itch (La Gâle); it does not injure the sheep or their wool, and cures this troublesome cutaneous disease in that animal. Its adulteration is hardly probable in view of the cheapness of manufacture and the consequent want of encouragement in the substitution of other tars. Samples were exhibited of the oil of cade sold in Vienna, in New York, and directly from a firm in Nimes, M. Saguier et Fils. The physical appearances of these specimens hardly differed from each other. Another sample of oil of beech (Oleum Betulæ) was also exhibited, whose physical appearance was distinctly different, and could hardly be mistaken for the commercial oil of cade. Since there is no known test for the purity of such a homogeneous mixed tarry product as the oil of cade there could be no advantage in putting this substance of indefinite and unknown chemical character in the official list of the United States Pharmacopœia, and hence its omission from that official work. A specimen of oil of tar which has a definite character, and is recognized in that Pharmacopœia by tests of its specific gravity and chemical reaction, was also exhibited for comparison with the unofficial oil of cade. The amount of oil of cade manufactured and sold at Nimes is not very considerable.

Dr. Amory asked if oil of tar possessed the same value as oil of cade as a parasiticide.

Dr. White had never used oil of tar.

Dr. Greenough believed that oil of cade possessed no special advantage over oil of tar, except in not having so bad a smell: he had never used oil of tar.

Dr. G. L. Walton reported

A CASE OF HYSTERICAL HEMIANÆSTHESIA, CONVULSIONS, AND MOTOR PARALYSIS, BROUGHT ON BY A FALL.[1]

In reply to a question by Dr. E. W. Cushing, Dr. Walton said that there was no displacement of the uterus or other evidence of local injury which could give rise to reflex symptoms.

AMPUTATION AT THE HIP-JOINT.

Dr. Bradford showed a boy on whom the operation of amputation at the hip-joint had been performed a year before for extensive disease of the hip-joint and pelvis; some sinuses remained still discharging from the caries of the ilium, but the boy had doubled in weight since the operation, and was now in excellent condition.

Dr. A. T. Cabot said that the firm condition of this stump was of interest apropos of a case reported by Mr. Shuter to the London Clinical Society,[2] in which he had performed subperiosteal amputation with the production of a long stump with a hard core, presumably of bone. This patient could wear an artificial leg comfortably, and could walk a considerable distance upon it without much fatigue.

This result is of great interest when we consider that of all the cases of successful hip amputation in our late civil war not a single patient has been able to wear with comfort a prothetic apparatus.

Dr. H. C. Haven reported a Probable Case of Pernicious Anæmia in a Child: the paper was reserved for publication.

CONGENITAL ARREST OF DEVELOPMENT.

Dr. J. P. Reynolds alluded to a case of congenital arrest of development he had recently seen in a newborn infant. The child was well developed, except in the median line of the face: there was depression of the superior maxillary bone, double cleavage of the roof of the mouth, strabismus of both eyes, and constant trismus. The infant seemed likely not to survive long.

ENCEPHALOID KIDNEY.

Dr. A. P. Weeks exhibited an encephaloid kidney, weighing nearly four pounds, which he had removed post mortem from a woman sixty-two years of age. There had been progressive failure of strength and, for the past few months, inability to retain food: there was no pain. Examination of the urine gave negative results, there being no blood and no albumen. No tumor had been discovered before death: consciousness was lost only at the last. The autopsy revealed the encephaloid mass, which was not adherent, and might have been removed by operation; the other kidney was healthy.

Dr. C. P. Putnam alluded to a case of scirrhous kidney, lasting two years, in which there was no albumen in the urine, but sometimes sugar. A tumor of almost the same shape and size with that exhibited by Dr. Weeks could be easily felt extending one inch across the median line. There was also some disease at the apex of the right lung, and atheroma of the aorta.

BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

WALTER CHANNING, M. D., SECRETARY.

The Society held its twenty-third regular meeting on the evening of November 20th at the house of Dr. Jelly, Dr. Fisher occupying the chair.

Dr. J. B. Ayer read the regular paper of the evening, entitled

A CASE OF CEREBRAL EXHAUSTION (IN THE EARLY AND RECOVERABLE STAGE) FOLLOWING NEURALGIA AND OVERWORK,

of which the following is a summary:—

The patient, now thirty years of age, has been a hard-working business man during the past ten years. He has never been robust, but there is no hereditary tendency to nervous or other forms of disease. Although he has suffered from neuralgia of the scalp, with accompanying dull feelings in the head, during the past seven years of our acquaintance, he has always been able to attend to business up to last February, when he was prostrated by an attack of influenza of a fortnight's duration.

In April he suffered severe pain from an attack of herpes zoster, and in July from neuralgia of the forehead.

[1] See page 558 of this number of the Journal.
[2] British Medical Journal, February 17, 1883.

During the preceding year his responsibilities had worn upon him, but he had been benefited by business trips.

He gradually regained strength after the attacks of influenza and herpes zoster, but the neuralgic attack of July was followed by physical prostration and the symptoms of a *tired brain*.

On the seventeenth day from the commencement of the neuralgic attack he was able to go to the sea-shore, and soon found that he could sleep a few hours without sedatives. He no longer complained of pain, but of a "dull, tired feeling," generally referred to the top of the head. Conversation, and all forms of exercise, tired him; the night sweats were debilitating.

Gradually the "gloomy, indescribable feelings" troubled him less and less. At times he would have a good day and feel badly in the evening.

The dull feelings came suddenly and went suddenly. He was quite depressed during their continuance, but the moment they disappeared he was again in good spirits and feeling well. The mind was always clear, and there was little heat of the head. In sailing he found the best diversion.

Ten weeks from the commencement of the neuralgic attack found him still troubled two or three hours of the twenty-four with the "dull, depressed feelings," but he was able to read, write, and converse without exhaustion.

He went on two occasions to his office, and found that he could attend to business and to complicated figures for an hour or two, but was very tired afterward.

Now that his physical condition had improved he worried about the slowness of the mental recovery, for formerly he had rallied quickly after an attack of neuralgia. Dr. Jelly at this time saw him with me, and assured him that the disease was functional, the slow recuperation of the brain-cells in the present attack being explained by extreme debility following overwork and three recent acute attacks of disease.

He tried a sea trip, and returned in five weeks much improved in every particular. Still he complained of disagreeable feelings in the head, — sometimes of distention, but generally of a dull feeling which he could not describe satisfactorily.

As his physical condition was excellent I felt that I ought not to advise him to remain idle, as I knew that he would worry about himself unless his mind were kept occupied.

At the end of fifteen weeks from the commencement of the neuralgic attack he began to attend again to his business duties, promising to favor himself, and to spend several hours daily in recreation. He is now recovering satisfactorily, and will, I trust, in a few months be well.

In remarking upon the case Dr. Ayer said: "Cerebral hyperæmia does not seem to me to explain this condition of the brain. I would agree with the review of Dr. Hammond's work in the *British Medical Journal* for 1880: —

"Hyperæmia may be *one* of the conditions present, this we have long looked upon as probable, but we are inclined to think that the main factor in these cases is impaired nutrition of the brain through exhaustion of the nervous elements."

Radcliffe says "there is no good reason for thinking that any one symptom points to cerebral congestion. I can find no better name for this disease than brain-exhaustion."

As Fothergill says: "Man has a reserve of force like the balance of a prudent firm at its bankers. If this is too far drawn upon a sudden demand becomes a very serious matter." He is also correct when he says, "A mind at once powerful and coarse of fibre has a great advantage as regards sheer endurance over another mind of finer fabric."

Dr. Ayer raised the question whether brain exhaustion was specially induced by cranial neuralgia, and stated that he believed that *functional* brain disease could be favored by the intense fears and worries of a patient with an aching scalp.

The responsibility of the physician was dwelt upon. He must win the patient's confidence, and, remembering that a neurasthenic patient always looks upon the gloomy side, he must constantly cheer him, and encourage him to make light of his gloomy, depressed feelings. "Every man," says Fothergill, "should strive with all his might to maintain the supremacy of the will over his volitional and emotional conditions. He must resist with what power and energy he possesses the demon force which is striving to enslave him if he wish to remain a freeman. Whenever bodily disease shall have enervated the mental powers or palsied their energies, then subjected morbid ideas will rise in active revolt, reinvigorated and inspired by the hope of success. A clear comprehension of this matter will give confidence and inspire hope in every one who has fought the battles of these emotional civil wars." The physician cannot too thoroughly understand that his patient's recovery may depend upon his words of encouragement.

As to the resumption of business duties, it may be necessary, if the patient is tired of travel and of idleness, to allow him to gradually resume work before he has fully recovered, provided he is physically strong; otherwise the morbid feelings may succeed in securing control over him.

In the discussion which followed the reading of Dr. Ayer's paper DR. WEBBER said that he thought that Dr. Ayer had not laid quite stress enough on the pain accompanying neuralgia. It is not the neuralgia in the head alone, but pain from neuralgia in any part of the body which is exhausting in its effects.

In these cases of nervous exhaustion one of the most difficult problems to solve is when the patient is in condition to return to work. Patients may get hypochondriacal when they have nothing to do but watch themselves, yet they may not be in condition to bear much mental strain. Foreign travel is often too great a strain, accompanied as it usually is with too much variety and change of scene, and patients easily overdo themselves. He usually tried to discover any tastes outside of their routine business they might possess, and in moderation to gratify these tastes. He had found that unless patients were very much broken down it was hard for them to do nothing.

DR. WHITTEMORE had found travel of very considerable benefit in two recent cases he had had. In the first case the patient had not been out of Boston for eighteen years. He slept little, and was depressed. After much difficulty he was made to leave Boston first for a short time, and then for a longer period, and he had gradually recovered. The second case owed his recovery to a journey to Europe.

Dr. Whittemore thought it well to encourage young men to go hunting and fishing, as nothing was better to establish health than an out-door life. Young

women, he thought, were also often benefited by a similar life.

DR. TUTTLE asked if such a case as Dr. Ayer had described might not degenerate into a case of melancholia if not recognized early.

DR. FISHER said that as far as his experience went cases of nervous exhaustion were not apt to end in melancholia though they remained for a long time in a threatening condition. In the city lunatic asylum he had several patients under his charge who were in a condition which might be regarded as the extreme type of nervous exhaustion, sometimes called *struporous* insanity. Most of the males were masturbators; one was a case of katatonia. Of the females two suffered from dysmenorrhœa, and in these cases pain seemed to exert an important influence as a causal element.

DR. CHANNING said that he agreed with Dr. Fisher that nervous exhaustion was rarely followed by melancholia. The former seemed to be a slowly arrived at change, essentially chronic, while the latter followed disease or some moral shock.

DR. WEBBER said that he remembered only two cases of melancholia supervening on nervous exhaustion. In both of these cases grief seemed to be the cause of the depressed condition.

DR. WHITTEMORE asked if the asylum physicians present were in the habit of feeding their patients on large quantities of food.

DR. STEDMAN said that he had given a patient twelve eggs a day, after the plan of Dr. Clouston.

DR. CHANNING had given fifteen eggs with two gallons of milk.

DR. WHITTEMORE said that a male patient at the Massachusetts General Hospital, with abscesses of the legs, had taken thirty-seven eggs in addition to a liberal general diet.

DR. JELLY said that he had noticed that patients taking large quantities of milk had unusually large fæcal discharges.

DR. WHITTEMORE and others had noticed the same thing.

DR. WEBBER said that he had tried experimentally to ascertain how much milk was required to sustain life while performing its regular duties, and he had found that he could do his own work on five quarts of milk a day.

DR. FISHER stated that he had lived for three months on milk and crackers.

DR. WEBBER, in answer to a question of Dr. Channing, said that he rarely put cases of nervous exhaustion to bed, and fatted them on milk. A modified plan of this treatment he had confidence in.

FACIAL NEURALGIA.

DR. AYER asked if the gentlemen present had used menthol in cases of facial neuralgia. He had had satisfactory results with a mixture of one part of menthol to ten of alcohol.

DR. WHITTEMORE spoke of a successful case in which the essential oil of peppermint had been used.

DR. JELLY had had partial success.

DR. WEBBER spoke of a proprietary remedy for neuralgia which was only menthol.

CAUSE AND TREATMENT OF APOPLEXY.

DR. JELLY asked the opinion of the Society in reference to a patient he had lately seen. This patient, a male of about fifty, has recently had a light attack of apoplexy, of which the chief indications now are slight impediment in speech, exaggerated patellar reflex, and slight mental weakening. Could a chancre which the patient had thirty years ago be responsible for these symptoms? Would antisyphilitic treatment be desirable?

The Society doubted as to the answer to the first question, but agreed that antisyphilitic treatment was entirely justifiable.

DR. FISHER described the case of a lady of sixty-five, who, a year or two ago, had a slight apoplectic seizure followed by one-sided facial paralysis. Within two months another attack occurred in which the facial muscles were drawn to the other side of the face. A month ago there was a third seizure, affecting the muscles of deglutition. The patient was unable to swallow solid or liquid food, and when Dr. Fisher saw her she had taken no food by the mouth for ten days. A few rectal injections had been given her. He was able to introduce liquid nourishment with the nasal tube, and at the end of a week she was able to take food herself, and continues to do so.

The question of location of the lesion was interesting in this case. At first he thought it might be bulbar paralysis, but he had lately seen a somewhat similar case ascribed to a bilateral lesion of the lenticular nucleus.

SEVENTH, EIGHTH, AND NINTH ANNUAL REPORTS MADE TO THE BOSTON MEDICAL LIBRARY ASSOCIATION ON OCTOBER 7, 1884.

BY JAMES R. CHADWICK, M. D., LIBRARIAN.

IT gives me pleasure to announce the uninterrupted prosperity of the library and building committed to my charge.

In the three years which have elapsed since my last printed report (sixth) the total number of volumes has increased from 10,123 to 14,699 volumes, being at the rate of 1588 volumes a year. The number of pamphlets has increased from 5678 to 12,289.

I would call your attention to the amount and value of the work that has been done to render your collection most serviceable to those who consult it. The task of collating and classifying the books and pamphlets, which has been most thoroughly done by Mrs. Collins, was completed in 1883. The expense of this great undertaking was defrayed by the late Dr. Calvin Ellis, whose total donation on this account amounted to more than a thousand dollars. The cross-references in the catalogue have been revised by Drs. J. W. Farlow, E. H. Bradford, A. Post, E. G. Cutler, J. B. Ayer, G. B. Shattuck, A. N. Blodgett, and myself. During the past year Mrs. Collins has, by direction of the Executive Committee, collated and catalogued the accessions to the library, so that the whole collection is now available for consultation. Dr. F. H. Brown has voluntarily undertaken to arrange and classify the large collection of catalogues of medical schools, annual reports of hospitals, dispensaries, etc., etc., which have hitherto been in a chaotic state. To him and to the other coadjutors mentioned are due the warm recognition of the Association.

A special department of the library in which your librarian has taken much interest of late is the collection of autographs. This originated in the very choice lot of medical letters addressed to Gov. John Winthrop, Jr.; it has since been enlarged by several hun-

dred letters from the correspondence of your librarian; by nearly two thousand autograph letters given by Dr. Edward Jarvis, which had been received by him during the sixty years of his professional activity; by some very interesting letters relating to the discovery of surgical anæsthesia from Dr. Benjamin Cushing; and, finally, by 128 letters from many distinguished physicians presented by the Hon. Nahum Capen, LL. D. Further contributions of documents, letters, etc., of medical interest are earnestly solicited.

Many hundreds of these papers have been cleaned, pressed, and mounted, free of expense to us, by Dr. and Mrs. J. H. S. Fogg, of South Boston. The remainder are being mounted gratuitously by patients of your librarian, an occupation which has proved of great therapeutic value to the persons thus engaged.

Without attempting to specify the source from which has been derived all our accessions, several donations call for mention. In the three years covered by my report we have received by bequest of the late Dr. Thomas B. Curtis his library of over 500 volumes and a large number of pamphlets, a collection specially rich in standard works and monographs, chiefly French, relating to surgery and genito-urinary diseases; from his widow, Mrs. H. Regina Gray, the library of the late Dr. F. H. Gray, consisting of 85 volumes; from his widow, the library of 194 volumes which belonged to the late Dr. James Morrison, of Quincy; from the publishers, William Wood & Co., of New York, their Standard Medical Library for four years, amounting to 48 volumes; from Miss L. Prince, 129 volumes from the library of her brother, the late Dr. W. H. Prince, of Newton; from his widow, the library of the late Dr. A. B. Bancroft, of Boston, numbering 279 volumes; finally, from his sister, Miss Lucy Ellis, carrying out his often-expressed intention, the library of the late Prof. Calvin Ellis, of Boston, consisting of 698 volumes, and constituting one of the most valuable lots of books that our library has received.

The expense of binding all the unbound books in the library of Dr. T. B. Curtis was defrayed by his brother, Mr. Lewis Curtis; and of those in the library of Dr. Calvin Ellis by his sister, Miss Lucy Ellis.

By an arrangement recently made by your librarian with the Faculty of the Harvard Medical School we have received all its collection of periodicals and a great portion of its general library, with the understanding that the Faculty of the School has the privilege of taking in exchange from our present accumulation of duplicates such books as the School wants to fill up its special libraries to be maintained for the use of its several laboratories. By this exchange we have been able to complete many files of the older periodicals, and add several hundred volumes of old standard works to our shelves.

By frequent visits to the medical libraries of other cities your librarian has been able to effect many exchanges, by which our files of periodicals have been largely augmented and in many sets completed. We are especially indebted to Dr. J. S. Billings, of the Surgeon-General's Library in Washington, for liberality in sending very many numbers of journals, all wanted in our files, upon exchange account, and to Dr. F. H. Sheppard, librarian of the Medical Department of McGill University in Montreal, for a like liberality in giving us nearly a thousand numbers of journals without immediate return. This wise and generous spirit is in marked contrast with the narrow policy of a few of the medical libraries who hoard their stores of duplicate periodicals on the mistaken idea that they have, or will come to have, a market value. My plan has been to practice the utmost liberality in the matter of exchanges, which has, I believe, inured to the ultimate benefit of our library.

The collection of medical portraits in our Hall has received several notable additions. A fine portrait by Vinton of the late Dr. T. B. Curtis has been intrusted to our safe-keeping by its owner, the Society for Medical Improvement. A bust, in plaster, of Dr. Benjamin Waterhouse, by Jackson, has been presented to us by Dr. H. P. Bowditch. A bust, in bronze, of the late Dr. J. Marion Sims, by Dubois, has been offered us through your librarian by an anonymous patient and friend, which will be received within a week. From his widow we have been the recipients of a large, handsomely-framed photograph of the late Dr. Samuel L. Bigelow, late of Paris, France, formerly of Boston.

The increase in the income of the Association during the past year has enabled the Executive Committee to authorize the expenditure of a larger sum of money than heretofore for its varied purposes. Twelve hundred and seven volumes have been bound. The drains of the house have been put in thorough repair at a cost of about $400. The system of heating and ventilation, which had proved defective in the past, has been overhauled and modified during the past summer under the direction of Prof. S. H. Woodbridge, of the Massachusetts Institute of Technology, whose system for heating and ventilating the new building of the Institute has proved such a marked success. To Mr. Thomas Windsor, formerly librarian of the Medical Library of Manchester, England, we are under many obligations for purchasing for us, at very low cost, the volumes which were needed to complete our sets of the Reports of the London Hospitals, full sets of the Transactions of the Pathological Society and of the Clinical Society of London. These accessions fill a gap that was often felt. The same increase in available funds has made possible the purchase of many recent publications, which have been assigned to a newly created department of our library, the Circulating Department, which has been organized by Dr. W. L. Richardson, as a sub-committee of the Executive Committee, to whom the Association is indebted for the gift of a revolving book-case for its accommodation.

By the plan adopted, all new books, bought for the library, may be taken out by members of the Association at the rate of five cents a day. Fifty-one volumes have been added to this Department between January 24, 1883, and October 1, 1884. Ninety-six volumes have been loaned to forty-two readers. By this scheme the convenience of readers has been met, and a portion of the cost of purchasing the books has been returned to the library.

The subjoined report of Dr. F. C. Shattuck, chairman of the Committee on the Directory for Nurses, displays most strikingly the admirable features and efficient management of that department of our institution.

Finally I have to assure you of the efficient coöperation of all your officers to promote the usefulness of your library to its members, to the profession, and to the public.

Subjoined will be found a statistical report of the present condition of your library prepared in conformity with the previous reports by Dr. E. H. Brigham, assistant librarian.

REPORT ON THE DIRECTORY FOR NURSES, 1883–1884.

The work of the Directory has gone on smoothly during the year, and it is gratifying to note that the number of calls from beyond the limits of Boston is increasing as the merits of the Directory become more widely known. Physicians find that it is much easier to telegraph to us for a nurse than to hunt one up at home.

The whole number of nurses registered since the Directory was opened is	621
Died or dropped	14
Now registered	607

They are classified as follows: —

Female nurses, non-graduates of training schools	380
Female nurses, graduates of training schools	155
Masseuses	9
Male nurses	60
Masseurs	3
	607
Number of nurses furnished during the year	1143

FREDK. C. SHATTUCK, M. D.
Chairman of Sub-Committee on Directory for Nurses.

Recent Literature.

Diseases of the Nose. By CLINTON WAGNER, M. D., Professor of the Diseases of the Nose and Throat in the New York Post-Graduate Medical School, Senior Surgeon Metropolitan Throat Hospital, Fellow of the American Laryngological Association, etc. With Illustrations of Instruments and Pathological Conditions. New York: Bermingham & Co. 1884. Price $2.50.

Notwithstanding the fact that this book is based upon an experience of fourteen years devoted exclusively to diseases of the throat and nose, we meet with not a few statements among the good things contained in it which we think will not be accepted by all workers in the same field. Speaking of rhinoscopy in the preface, the author surprises us by saying that any one competent to make examinations properly by the present known methods, and who has a fair knowledge of the anatomy of the parts, requires no special skill or training for performing the operations on the nose daily undertaken by specialists; and on page 47 we learn for the first time that the examination of the posterior nares is one of the most difficult manipulations known to surgery. Hitherto we had supposed that any one of average ability could be taught in a few minutes how to examine the posterior nares (the correct interpretation of what one sees is quite a different matter), while the operations on the nose, we believed, *did* require special training, and could be performed as they ought only by the experienced specialist. We commend, in the main, the portions of this volume which relate to the treatment of the various diseases found in the nasal cavities, and they show that the author is a careful and good practitioner; but the work as a whole, we regret to say, is so carelessly put together and so shockingly illustrated that it will wound the feelings of every one who has any respect for the nose. Never before have we seen so many wretchedly-executed wood-cuts collected together in a single volume. We doubt if Boston's champion pugilist could more effectually pound a nose beyond all hope of recognition than is the curious picture (presumably of that organ) on page 12. Figs. 1, 3, and 5 are almost equally incomprehensible. Nearly an entire page (136) is devoted to a cheap wood-cut which means absolutely nothing, nor is it a likeness, we are sure, of anything that is in heaven above, or in the earth beneath, or in the water under the earth. The typographical errors, moreover, are simply inexcusable. Professor Schiff figures in the text (page 29) as *Shift*. Our old teacher Zuckerkandl and his classical work are referred to (page 25) as Zùcherkarel, E. — Zùr Anatomie ùnd Pathologie der Nasenhöhle, Wien, 1880; really this is too bad. We find these little accents scattered through the book in the most unexpected places, and they impress us as if some one had taken them between the thumb and forefinger and snapped them in anywhere, regardless of their signification. The volume ends with a Bibliography, and here again errors of omission and commission follow each other with such startling rapidity that it must be thoroughly revised to prove of any value. The following is one of many puzzles which occur on page 239: Busheh, Behandlung der Sogenanten Ozæna. Litzungst. d nied rhein — a bold abbreviation, indeed, of "Sitzungsberichte der niederrheinischen gesellschaft für Natur

und Heilkunde zu Bonn," to say nothing of the misspelling of the proper name, and the absence of any date or number of volume. But we are glad to be able to part with this volume with a word of praise. It has a very neat and attractive cover. We gain encouragement, also, from the motto — *Ne tentes, aut perfice* — which we find on the title-page, and we earnestly hope that advantage will be taken of the rich opportunity which this book affords for its practical application, so that a future edition may come somewhere near being worth the price asked for it. F. H. H.

The Atlas of Female Pelvic Anatomy. By D. BERRY HART, M. D., F. R. C. P. E. Lecturer on Midwifery at the School of Medicine, Edinburgh. New York: D. Appleton & Co. 1884. (With a Preface to the American edition by Dr. Alexander Skene.)

We regret our delay in noticing this work, which both from the originality of its design and the success of its execution will occupy a high place. It appears to have been Dr. Hart's intention to present a series of pictures that should show so clearly the points at issue that any long description or discussion would be superfluous. In this he has been very successful. He has had the advantages of study in Germany and familiarity with German methods which he turns to good account. The work is, however, not without faults. One of them is its division into curiously arbitrary sections. The first, comprising seventeen plates, is called Descriptive; the second, Dissectional; the third, Sectional and Topographical; the fourth, Structural and Genu-pectoral Anatomy; the fifth, The Cervical Canal during Pregnancy and Parturition; the sixth, Microscopical Anatomy. Excepting the last two all these divisions seem entirely artificial. The plates are in part original, in part taken from various authorities always with due acknowledgment. We are inclined to consider that Dr. Hart has been rather too free in his selection, reproducing several that add little to the value of the work.

We will now pass quickly in review the chief features of the work. Plate I. presents the bones and ligaments of the pelvis, and we must own that we are rather surprised at Poupart's ligament in Figure 2, which seems to us to include a good deal of the aponeurosis of the external oblique.

In the description of Plate II. we find that, following Henle rather than English anatomists, Dr. Hart describes the nymphæ as covered with skin instead of mucous membrane.

Plate III., representing various forms of the hymen, is poorly executed.

In Plate IV. Dr. Hart reproduces, if we mistake not, one of his own plates showing the vagina as a slit and not as a tube as it is frequently represented. He gives the posterior length as three and one half inches and the anterior one inch less.

Plate V. has a figure from Pirogoff showing a frozen section of a distended bladder and rectum. The following plates contain figures from the works of Rüdinger, Bourgery, Jacob, Hyrtl, and others, showing many of the less well-known points of the anatomy of the pelvic organs. The views indicating their immense blood supply are particularly instructive. We regret that among them is a figure from Polk showing a cylindrical vagina in direct contradiction to the author's teaching, and a similar monstrosity by Schultze occurs later. We cannot see why a plate showing lymphatic enlargement in malignant disease should appear in this section or indeed in the work.

In the third section there are admirable frozen sections demonstrating the relations of the pelvic peritonæum in various conditions.

With regard to the disputed question of the position of the uterus and the annexa, Dr. Hart declares one might as well attempt to give the position of a pendulum in motion. As for the ovaries he simply says that they lie behind the broad ligaments at the level of the pelvic brim with their long axes varying in direction. We may mention that our author has declared in an earlier part of the work that the idea of the fimbriated extremity of the tube grasping the ovary during menstruation is imaginative.

Hart divides the floor of the pelvis into the movable and immovable portions; the former extends from in front to the anterior border of the rectum and as far out as the edge of the levator ani; the fixed portion is the remainder. "Neither the perineum, nor the perineal body, nor the posterior vaginal wall alone support the uterus and abdominal viscera. They do so only as parts of the entire fixed portion of the pelvic floor. Thus the uterus, abdominal viscera, and the entire displaceable part of the pelvic floor rest on the entire fixed portion, that is, do not rest on the perineum or perineal body alone."

The effect of the genu-pectoral position is discussed and illustrated by two frozen sections of the body from the top of the head down.

Dr. Hart's views on the contraction of the bladder are rather curious. He had already shown by frozen sections of his own and from those of others that the female bladder may be found empty in either of two positions. One is such that a median section shows the cavity of the bladder and urethra in the shape of a Y, the upper vesical wall resting within the lower. In the other form the anterior and posterior walls are in contact, but a great difference is that in the latter case the walls are very thick and in the former they are thin. From this Dr. Hart concludes that as the bladder contracts it assumes the latter form and subsequently relaxes into the former, which he rather unnecessarily, to our thinking, compares to a systole and diastole.

The author quotes American as well as European writers — Dr. Chadwick on the rectum and Dr. Ranney on the pelvic fasciæ.

The book is a large quarto, very finely printed, and the plates are excellent, with perhaps one or two exceptions. It will add to the author's reputation, and rank among the standard works on the subject.

T. D.

Pathologie und Therapie der Frauen-Krankheiten nach den in den Feriencursen Gehaltenen Vorträgen. Bearbeitet von DR. AUGUST MARTIN, Docent für Gynäkologie an der Universität Berlin. Wien und Leipzig: Urban & Schwarzenberg. 1885.

This book of 400 odd pages embodies the lectures delivered by Dr. Martin, of Berlin, in the vacation courses which are more especially intended for practitioners. It is, therefore, not adapted for students for two reasons. In the first place it omits much that is essen-

tial for the beginner, the A B C of gynæcology, and in the second place it largely treats of operative procedures which none but the specialist should undertake. It is condensed, except, perhaps, his descriptions of operations, which are given with all the fullness of detail which mark the enthusiastic surgeon. In fact, in this respect it is the best book we have seen since the Operative Gynæcology of Hegar and Kaltenbach appeared.

As the book practically consists of what Dr. Martin has given in lectures to physicians, and is not intended to be a manual for students, the author has wisely confined himself to his own views and methods. We have, therefore, a book marked by personality and originality, and hence a readable book.

His chapter on Anatomy is short but good. We are glad to see that the position of the ureters is spoken of. As the extirpation of the uterus becomes more common their anatomical relations should be well understood.

The bimanual examination he justly considers by far the most important method. He, however, very strangely falls into the error of supposing that in this country it is made in Sims's position.

He devotes only a short chapter to Menstruation and its Disorders. He inclines to the opinion that ovulation and menstruation are not entirely independent functions. Intermenstrual pain he considers physiological, but does not pretend to give any satisfactory explanation of its occurrence.

The chapter on Malpositions of the Uterus is in general very good. The caution which he displays everywhere through the book with regard to even the simplest treatment is especially marked here. He is inclined to limit the number of displacements which require treatment, first, by striking many cases of anteversion and flexion out as being merely physiological, and, second, by considering displacements with adhesions as peri- or parametritis, with dislocation of the ante- or retroflexed uterus. This may be pathologically correct in a certain proportion of cases, depending, of course, upon which was the first factor, the displacement or the inflammatory process; but therapeutically it is not, for the treatment which is of most avail in these cases is directed primarily to the displacement.

What is generally considered congenital anteflexion of the neck, with elongation, he says is not congenital, but the result of cervical catarrh. He lays great emphasis on the rôle that pregnancy and parturition play in producing displacements of the uterus, especially the backward forms, which he claims are rarely found in women who have not either borne children or suffered from a miscarriage. This is certainly contrary to our experience here.

For complete prolapse of the uterus he wisely recommends a plastic operation, and after describing several methods practiced by different German surgeons (he makes not the slightest reference to Americans), he describes his own operation, which, though thorough, and one that ought to secure the desired result, yet seems formidable if all the steps are to be taken at once, as he recommends. He begins by amputating the neck of the uterus, then narrows the anterior wall, then the posterior, and finally stitches up the perinæum. It is no wonder that he keeps his patients absolutely quiet for three weeks after such a series of operations, and only removes the uppermost stitches after two or three months.

The chapter on Diseases of the Mucous Membranes of the Uterus is especially good as regards the pathology, and his treatment of laceration of the cervix leaves nothing to be desired. So, too, his treatment of stubborn cervical and corporeal catarrhs. He is at his best when describing the operations of amputation or removal of the uterus for fibroids or malignant disease, both by the abdominal and vaginal methods. These operations have in his hands shown good results. His rule of operative procedure in cases of cancer of the cervix is, when the diagnosis has been made sure microscopically, to proceed at once to the extirpation of the uterus. We cannot but feel that if more care were bestowed on less radical measures the results would repay. Such, at least, has been the experience not only here but in Europe.

The section on Diseases of the Tubes is well up to the present state of our knowledge of them, and he even includes tubal pregnancy, though strangely enough he omits any mention of electricity as a means of cure.

Taken as a whole the book is an exceedingly good and valuable one, and one which we can recommend to all gynæcologists who are familiar with German. The wood-cuts, of which there are one hundred and sixty-four, are most admirably done, and many of them are especially prepared to illustrate the points discussed. We have yet a long stride to make before we can equal in execution or originality the work of the Germans in this respect. The text is clear and the paper good.

Diseases of the Heart and Thoracic Aorta. By BYROM BRAMWELL, M. D., F. R. C. P. E., etc. With 317 Illustrations. 783 pages. New York: D. Appleton & Co. 1884.

In a foot-note to the preface it is written, "the subject-matter of the work was delivered almost exactly as it stands in the form of lectures to the author's class in the beginning of the winter session 1883–1884," a statement which awakes reflection in the mind of any one with some experience in medical instruction. The obligatory course of study at the University of Edinburgh is a year longer than with us, but, making full allowance for the extra year, we find it difficult to understand how the teachers can administer and the students digest such large quantities of mental food in the time if all the more important branches and subjects of medicine are treated with the fullness which characterizes these lectures. In spite of the well-known remarkable vigor of the Scotch race we are fain to believe that the mere end of instruction of students would have been better served had the lectures been condensed. Twenty-eight consecutive pages are devoted to the sphygmograph. The cardiograph has an appendix of twenty pages. Forty-five pages are given to the anatomy and physiology of the heart. Twenty more pages are occupied by an elaborate discussion of the theories advanced to explain the mechanism of functional murmurs. The author agrees with Balfour in thinking that in many cases of advanced chlorosis the systolic apex murmur is due to mitral regurgitation, but, contrary to Balfour, believes that this murmur is distinct from that heard at the base. The latter authority maintains that both alike indicate imperfect closure of the mitral orifice, though in varying degree. Russell's theory that the basic murmur is due to constriction of the pulmonary artery by pressure of the

dilated left auricle is also rejected, the author thinking that the weight of evidence favors the view according to which the murmur is produced by "the *sudden* propulsion of a *large* blood wave of *abnormal* composition[1] into the vessel, which is, probably, in some cases at least, dilated."

This very completeness, which is carried out in almost all parts of the book, and which if it be an error as regards the relation of a teacher to his pupils is, at all events, an error in the right direction, becomes an unqualified merit as regards the relation of an able and competent physician of large experience toward his professional brothers. Looking at Dr. Bramwell's book from this latter point of view we can scarcely use a word that is not of praise. The only fault we have to find is that the work is, we fear, too expensive to secure the large sale which it deserves. The beautiful plates in which it abounds do not add to the value in the same proportion that they add to the cost. At page 300 are four full-page, natural-size lithographs illustrating pericarditis and our criticism alike. There are few who would be likely to buy the book or profit from it when bought who have not seen inflamed pericardia, still fewer who have not seen inflamed pleuræ, and it is a pity that the many should pay — or lose more by not paying — for the neglect or want of educational advantages on the part of this fraction of the profession. This criticism, which sounds rather ungrateful from a reviewer, springs really from appreciation of Dr. Bramwell's labors.

One passage we cannot refrain from quoting *in extenso:* "The advisability of communicating to or withholding from the patient the knowledge that the heart is diseased is a question which always requires careful consideration. In most cases it is, in my opinion, highly desirable to deal frankly, though, of course, the very reverse of abruptly, with the patient; for unless he realizes the fact that his heart is organically diseased he cannot intelligently carry out our instructions as to treatment, and he does not guard himself so carefully as he otherwise would do against many things, such as over-exertion, exposure to cold, etc., which aggravate the disease or induce complication. In some cases the communication should be made in a very guarded manner, and in the case of very nervous and easily depressed people it is occasionally, though rarely, desirable to withhold the information altogether. In cases of this description the physician should take care to protect himself against accidents by communicating the exact condition of the patient to some judicious relative, for should this communication not be made, and the fact that the heart is affected be subsequently discovered (by some other physician, for example, or by the death of the patient) it may be supposed that the cardiac lesion was not recognized. In all cases of mitral regurgitation in which the patient is informed of his condition he should be impressed with the fact that the lesion has little or no tendency to result in sudden death."

This is a practical point which is too often neglected by authors, and Dr. Bramwell's statement accords so thoroughly with our own preaching and practice, and is at the same time so clear that we cordially indorse it to the full. Let the physician only be careful to be sure of his diagnosis, remembering that time may be an important factor in distinguishing between organic murmurs and those which are merely functional.

[1] The italics are Dr. Bramwell's.

In conclusion we can heartily recommend the book, especially to those who do not cease to be students though they have taken their degrees. F. C. S.

On Sclerosis of the Spinal Cord: including Locomotor Ataxy, Spastic Spinal Paralysis, and other System-Diseases of the Spinal Cord: their Pathology, Symptoms, Diagnosis, and Treatment. By JULIUS ALTHAUS, M. D., M. R. C. P. New York: G. P. Putnam's Sons. 1885. Pages xii., 394.

A very simple yet true remark begins the book: "There is no pathological term which is nowadays so freely and somewhat loosely used in speaking and writing about the diseases of the nervous system as the word sclerosis. . . . In practice any obscure and chronic case of nervous disease is now often spoken of as 'a case of sclerosis,' which is supposed to explain everything, and it cannot be denied that there is a good deal of confusion in the professional mind about what sclerosis really means and comprehends."

This book clearly describes the morbid anatomy and symptoms of the diseases of which it treats. The arrangement is a little different from most works on these diseases. After a brief anatomical introduction, the pathological anatomy of the different forms of sclerosis, — tabes spinalis, lateral sclerosis, secondary sclerosis of the pyramidal strands, of the cerebellar strands, of Goll's columns, amyotrophic lateral sclerosis, disseminated sclerosis in patches — are minutely described. A chapter is then devoted to the ætiology of all these, and finally their symptoms are given, and the treatment of each.

About a third of the book is given to locomotor ataxia, or, as Althaus prefers to name it, tabes spinalis, and this is much the more important of the diseases considered. The account of its symptoms is full, satisfactory.

In the chapter on Diagnosis the author refers to the value of absence of tendon reflex as a pathognomonic symptom, and an important aid in distinguishing tabes from other affections. He gives this symptom its proper place, and justly emphasizes its importance. By the way, he expresses the opinion that the knee phenomenon is a true reflex. The importance of Argyll-Robertson's symptom, when present, is also mentioned.

No mention is made of Déjérine's observation, in which multiple neuritis so closely simulated tabes that the diagnosis was not made until after death the microscope showed that the disease was confined to the nerves.

In speaking of the morbid anatomy and nature of tabes the author says that the first change "affects the axis cylinder of the central nerve fibre." While this probably does not express exactly what he means the idea one would gain is true. A review of all that has been written on this subject seems to have left an uncertainty and unsatisfaction in his mind, as he says, as if in despair of bringing order out of the chaos of opinions, "On reviewing the whole of the morbid changes which are found to take place in tabes they appear to us of an extremely complex character."

On page 4 he says: "All forms of primary sclerosis are symmetrical, and only exceptionally confined to one half of the organ." The patches of insular or disseminated sclerosis are not symmetrical.

Such expressions as "higher up," "later on," "lower down" are not uncommon.

We commend the book to any one who desires a not too long description of sclerosis of the spinal cord.

Medical and Surgical Journal.

THURSDAY, DECEMBER 11, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY, No. 4 PARK STREET, BOSTON, MASS.

N. B. After January 1, 1885, the Journal will be published by CUPPLES, UPHAM & CO., *283 Washington Street, Boston.*

AN AMERICAN SOCIETY OF PUBLIC ANALYSTS.

A CALL was issued in November last to all those holding official appointments under Boards of Health as analysts, inspectors, and health officers to attend a conference to be held upon the 24th of that month at the office of the Brooklyn Health Department. This meeting was well attended by representatives from the Middle and adjoining States. A constitution and by-laws were adopted, and the meeting adjourned to the regular day of meeting agreed upon, the second Monday of the next month, that is, to December 8th, when the officers for the next year were to be elected.

The name of the Society is to be "The American Society of Public Analysts." Its object is, by the holding of frequent meetings for the reading and personal discussion of original papers upon these subjects, to improve the processes of inspection and of the microscopic and chemical detection and estimation of adulterations in food or drugs, to secure uniformity in the statement of the results, and also to provide for a sanitary control of the food supply.

The proceedings and papers read will, probably, be published in *The Analyst*, the organ of the British society of the same name. The place of meeting may be at any of the different cities in which any of the members reside, although it is likely to be most frequently in New York. Membership is divided into active and honorary; active members to be only those holding official appointments as analysts and inspectors; any person interested in the objects of the Society may become an honorary member.

By the frequent meetings it is proposed to hold each member will be kept well informed as to what has been learned by all the others in the way of new adulterations, and the readiest means for their detection, as well as to the newest and most reliable means of defense in cases of legal prosecution. They will thus work together to expose all crookedness in regard to food or drugs, and follow up offenders as they move on from place to place.

By this concerted action it is expected that very much more can be accomplished than could possibly be brought about in any other way. It was for this that the similar British society was formed in 1874, and there the results have justified these expectations.

The British Society holds monthly meetings, and its proceedings are published in the *Analyst*, a semi-official monthly organ of the Society, though having a distinct editorial management.

Legislatures can be roused to spasmodic action by eager individuals, but they can only be held to sustain laws opposed to the selfish interests of trade by such collective presentation of technical knowledge and indisputable facts as the association together of men with a special training can furnish.

Men engaged in practical medicine find much personal benefit from conference and association, and those engaged in State medicine will find no less profit in them. What a Medico-Legal Society is to medical examiners, that a Society of Public Analysts will be to the analysts and inspectors attached to Boards of Health.

Much has still to be learned and taught as to the best methods of preventing adulterations of food and drugs, as to the best ways of detecting, prosecuting, and punishing offenders. Some of our States already have good laws and are making honest and vigorous efforts to enforce them, but even there mistakes arise, and in many States there are either no systematic laws or else they have been allowed to become a dead letter.

The preservation of the purity and quality of the one item of milk has proved almost as difficult a problem to many wise heads as that of perpetual motion or squaring the circle.

ORGANIZATION OF THE NINTH INTERNATIONAL MEDICAL CONGRESS.

THE Committee on Organization of the Ninth International Medical Congress, to be held in Washington in 1887, have issued a preliminary notice, received too late for insertion last week, which will be found in another column. We abstain from giving publicity to any other particulars which may have reached us until they are officially announced. The arrangements and appointment of officers thus far made public seem very judicious.

It seems to be positively decided that the Congress is to meet in Washington, and, as we understand it, in the month of September. There are, no doubt, many weighty reasons why the Meeting should be held in Washington, and, perhaps, every reason why no better month than September can be selected. We fear, however, that the choice of time and place will seriously interfere with the success and enjoyment of the occasion. The experience of the British Association for the Advancement of Science this past summer, when transferring itself from Montreal to Philadelphia, is a warning of what is quite likely to happen again. Even abstract science grows limp with the Fahrenheit thermometer in the eighties or nineties and removed

from even the temporary refreshment of sea or mountain air.

If sure of escaping malaria one might seek relief upon the Potomac of an evening, but there is too much danger of an unwelcome intermittent chill; and sufficient hotel accommodations, interesting national museums, a really beautiful city — not at its best in September, — and an arrangement with the Signal Service Bureau must be the alternatives under the apparently unavoidable conditions.

PLEURO-PNEUMONIA AND HOG CHOLERA AT NEW YORK AND LONG ISLAND.

AT a recent conference at New York at which Prof. C. F. Chandler, late President of the Board of Health, Health Commissioner Raymond, of Brooklyn, and other authorities in sanitary matters were present, the inspectors appointed last spring as agents of the new Bureau of Animal Industry of the Department of Agriculture, made their first report to Dr. Loring, the Commissioner of Agriculture.

The inspections made by them were for the purpose of learning the condition of cattle brought to the vicinity for slaughter, or to be kept for dairy uses, with special reference to the amount of contagious pleuro-pneumonia that was being harbored there. In 758 stables in New York City, containing 3318 cows, there were found twenty-six infected with the disease. On Long Island, 1416 stables were inspected, and among the 10,072 cows contained in them there were 325 cases. In the Staten Island stables there were found twelve cases, and in thirteen stables inspected in New Jersey eight cases. In the Jersey City Abattoir thirty-nine visits discovered thirteen affected animals, and at the New York offal dock out of sixty-three post-mortem examinations twenty of the cases were found to be pleuro-pneumonia. The report states that the result of the investigation has been to give a definite idea of the extent of the disease, and to secure great improvement in the condition of the stables.

The contagiousness of the disease has been proved by experiments made on Barren Island, in which healthy cattle, imported expressly for the purpose from Canada, were placed in company with diseased animals, and the report goes on to say: "We are confident that further investigation in this direction will enable us to decide upon the virulence of the disease as found in America, the time of incubation here, and the possibility of controlling it in those sections in which it may unexpectedly appear." Commissioner Loring expressed himself gratified with what had been accomplished, and Professor Chandler said that this was the first bold move in the right direction.

Dr. Raymond, of the Brooklyn Board of Health, and Dr. J. Blake White, of the New York Board, now propose, with the help of the inspectors, to investigate in what manner pleuro-pneumonia affects the milk of cows suffering from the disease.

Within the past week or two hog cholera has broken out in a very virulent form among the extensive piggeries at Flatbush, Long Island, and the animals are said to have been dying at the rate of fifty or sixty a day. The Brooklyn Health Department has been given notice that certain New York and Brooklyn butchers have bought a number of the dead hogs from the poorer owners, and carted them away at night. There are also reports of isolated cases of hog cholera on farms in the vicinity, and there is great fear among the farmers of the county that the disease will spread among pigs generally in that region. The disease is so infectious, contagious, and rebellious to treatment, that it is considered necessary by the best authorities to kill the animals at once and burn them and their sties, with the troughs, pails, litter, and all utensils used by them.

THE DISPENSARY DOCTOR AS SAINT STEPHEN.

ONE of the district physicians of the Boston Dispensary was stoned last week by a set of young hoodlums whilst discharging his beneficent duties in the relief of suffering. The part of the city where this occurred, Silver Street, South Boston, has gained an unenviable and increasing reputation for lawlessness of late years. This is thought to be due, not to the inefficiency of the police, who are said to be willing and able to discharge their duties, but to the apparent unwillingness of the local police court to pass sentence on offenders when brought before it. The court's usual practice of putting disturbers of the peace on probation seems to foment rather than to check disorder.

In the present instance the court gave an exhibition of vigor towards the visiting doctor which would be well bestowed at times upon the resident hoodlums. The doctor, in defending himself against the fate of St. Stephen, was unlucky enough to hit one of the smaller of the gang in the street over the head with his umbrella. Although in such bad company this lad immediately became an innocent victim besides being the son of a local politician. As the outcome of the matter criminal and civil suits against the medical agent of the Dispensary, which were not likely to thrive in the local legal atmosphere, have been settled for $125, and this seems now to be the established price in Boston for assaulting a tailor or for being stoned as a doctor.

The Dispensary has promptly abolished this South Boston District, and the physician will no longer be sent to exchange diet orders and medical advice for stones. The inhabitants of Gold and Silver Streets will have an opportunity to find out that the patient, sympathetic care and attention freely given them all these years is the result of individual private charity, and not their part of the spoils from a tax-rate of $17 on a thousand.

No charitable institution in Boston or in any other large city does a more gracious or much blessed work among the poor and suffering, or does it more unostentatiously and skillfully, than does the Boston Dispensary. Its ministrations have been continued so

many years that the classes of the community for whom they are designed regard their continuance with the same assured confidence as that they can have air to breathe and water to drink — should they desire such. On the other hand it is only fair to say that, hitherto, the Dispensary doctor — and most of us have borne the title — has been a privileged character. He has been able to go into the worst slums and most dangerous haunts at all hours of the day or night, and it has been the rarest thing where anything except courtesy and respect has been shown him. It seems to be reserved for South Boston to manifest a spirit which the North End or the South Cove would be ashamed of.

MEDICAL NOTES.

— The *Medical Record* tells the following story of the celebrated Oppolzer. Shortly after his arrival in Vienna he was consulted by an invalid, whom he advised, after a somewhat hasty examination, to go to Pistyan, in Hungary, and take the waters. After several months the man, whom the professor had forgotten, again presented himself with an aggravation of all his symptoms, and said he had just returned from a course of the Pistyan waters. The professor examined him, this time rather more carefully, and then, with some wrath, asked him what confounded ass had advised him to go there, as it was the worst thing he could possibly have done. Moral: Always speak well of your neighbor.

— On the 1st instant a law went into effect in Germany amounting to compulsory insurance. A certain premium is collected by law, as we understand it, from all persons. The benefits to be derived by the sick or disabled workman are gratuitous medical attendances, medicines, and appliances, and, after the third day, a money-allowance equal to half the daily wages, so long as it does not exceed seventy-five cents a day, for thirteen weeks. In case of death, a burial allowance will be made, amounting to twenty times the daily average wage of the locality. The details of the system have not as yet come to hand, but the principle, that of compulsory insurance, is settled, and its results will be looked for with interest.

PORTLAND, MAINE.

— The Cumberland County Medical Society held its annual meeting on the 26th of November. Dr. Stephen H. Weeks delivered the address, taking for his subject The Tendencies of Modern Surgery. After recounting some of the principal triumphs of surgery of late years, and instituting a comparison between the resources of the surgeon formerly and now, he proceeded to draw the inferences that the surgery of the present day tends, first, towards conservatism; second, to specialization; third, to the demand for a higher education; and fourth, to a better social position. Each of these points was carefully elaborated, and supported by argument and illustration; and the address gave great satisfaction to the audience.

For the first thirteen years of the Society's existence the meetings were held in the day-time, but in 1880 a change was made to the evening. One result of this alteration has been a great decrease in the attendance of the members residing in the country towns, as they find it inconvenient and difficult to get to their homes after ten o'clock at night. At this meeting the city men, desirous of having the out-of-town members enjoy the privileges of the Society, proposed and unanimously agreed to have the sessions in the future in the forenoon. The day of meeting, also, was changed to the last Thursday of each month. It is hoped that the new plan will secure a very large attendance.

The following officers were chosen for the coming year: President, A. K. P. Meserve, of Portland; Vice-President, J. L. Horr, of Saccarappa; Secretary, S. P. Warren, of Portland; Treasurer, J. A. Spalding, of Portland; Orator, A. H. Burbank, of Yarmouth.

— There are three private medical associations in this city: the Portland Medical Club, the Clinical Society, and the Practitioners' Club, named in the order of their establishment. The first has more than twenty members, and meets fortnightly; the others have a smaller membership, and hold monthly meetings, in which the social element is prominent. All three are in a very prosperous condition.

— The capacity of the Maine General Hospital has been greatly taxed of late, applications for beds being much in excess of the accommodations. The pressure will be removed, however, as soon as the new addition and amphitheatre are completed; for then apartments which it has been necessary to use for operations, students' waiting rooms, and servants' quarters will be vacated, and can be devoted to the immediate service of patients. The operating amphitheatre is nearly finished, and will probably be dedicated in a few weeks. A full description of the building will be given at that time.

— On the first of January next a training school for nurses will be established at the hospital. The need of such an institution has long been felt, but it has not been practicable to utilize the hospital for this purpose hitherto. The value of this service to the community can hardly be overestimated, and will doubtless be highly appreciated.

— The Portland School for Medical Instruction is especially prosperous this year. More than fifty per cent. of the students are college graduates — a fact largely attributable to the strictness of the entrance examinations.

— Another effort is to be made this winter to obtain a State Board of Health in Maine. The result is, of course, extremely doubtful, as the sentiment of the people is not well educated in sanitary matters. Under the stress of fear, occasional spasmodic displays of interest in public hygiene are made, but, as soon as the threatened danger seems to be past or the epidemic has committed its ravages, the former apathy settles down on the people, and they are deaf to the warnings of intelligent sanitarians. For instance, five years ago the citizens of Portland were vastly agitated by reason of certain bad odors, which were thought to

be due to the foul condition of our Back Cove. The newspapers were inundated with communications from alarmed and exasperated tax-payers, and the municipal authorities were sufficiently aroused to appoint a commission of physicians to investigate the causes of the difficulty. After a prolonged and careful study of the problem the commissioners reported, pointing out numerous sources of the nuisance, and advising certain procedures which would put the city in a safe and comfortable condition. But of all the recommendations only one was practically adopted, and that was of far less importance than a number of others. Very little further was said about the general causes of disease in the city until this summer, when, complaints becoming loud again, the City Council thought it well to bestir itself anew. Ignoring the fact that it already had a report on the subject from some medical men of its own choice, who were presumably competent to advise in the premises, it advertised a public hearing, at which all citizens who wished to attend were invited to give their opinions of the origin of the trouble and the best methods for its abatement. Thomas, Richard, and Henry were there, each with an explanation and a remedy different from all the others. Fortunately, as it then appeared, the Council adopted the suggestion of a wise man who had paid a great deal of attention to such matters, and employed an expert engineer to make a plan for an intercepting sewer which should receive the sewage from the northern slope of the city, and thus prevent its discharge into the Cove. The engineer came, made his survey, and reported; but, with a short-sightedness which has become characteristic, the admirable plan proposed was utterly rejected, and a make-shift sewer was ordered which will never do the needed work, and will probably tend to aggravate the present difficulty. Some years hence the work will have to be undone, and the city will be put to the expense of a new sewer, constructed on a scientific method. This bit of history is given merely as an illustration of the lack of intelligence in sanitary matters which prevails throughout the State. If a State Board of Health is established, its chief function for a long time must be the creation of an enlightened public sentiment on the subject of the preservation of health.

NEW YORK.

— At the last meeting of the State Board of Health Mr. James T. Gardner, Director of State Survey, called attention to the unsanitary condition of the flats at Albany, particularly the basin owned by the State, which is skirted by all the principal hotels and business houses, and into which the principal sewers of the city empty. The State is compelled by law to maintain a depth of seven feet at low tide, but long-continued deposits of sewage have filled up the basin. In addition the water used in Albany is pumped from the Hudson River, at a point near the channel where the water from this polluted basin flows into it, and thus the health and lives of many people are endangered. Mr. Gardner recommended that the city of Albany should be restrained from emptying its sewage into this basin, and that an appropriation be made to dredge it to the required depth.

— During the latter part of last month Mayor Edson, in company with General Shaler and a number of other officials of the Health Department, and Engineer Church, of the Aqueduct Commission, made an excursion for the purpose of examining the condition of the Croton water-shed. On their return it was stated that no fault could be found with the reservoirs or the bed of the streams from which the water comes, but at the villages along the course of the Croton and its tributaries they found evidence that sewage found its way into the water so as to slightly contaminate it. The distance from the points of the contamination to New York is so great, however, that the water is purified before it enters the city mains, though as the villages increase in size trouble may arise from this source.

Correspondence.

THE ASPIRATOR IN PLEURAL EFFUSION.

BOSTON, *November* 29, 1884.

MR. EDITOR, — In the record of the First Annual Meeting of the New York State Medical Association (*Boston Medical and Surgical Journal*, November 27, 1884) I find that Dr. E. D. Ferguson, of Rensselaer County, presented a paper on the Use of the Aspirator in Hydrothorax. He laid down the following propositions: —

"First. Owing to the dangerous and often fatal results which he had seen produced by the aspirator by causing pyothorax, he now never resorted to it except when dyspnœa or other serious symptoms supervened."

"Second. Dr. Bowditch had maintained that the aspiration should be continued until the patient complained of pain in the epigastrium or dyspnœa, but he (Dr. Ferguson) thought that it was much better that it should be stopped before this point was reached, as the occurrence of these signs indicated a more or less grave condition already.

"Third. He would advise that more than a pint of fluid, at the outside, should never be withdrawn at one time.

"Fourth. In the pelvic cavity much evil had resulted also from the too free use of the aspirator, and, on the whole, he thought the instrument had, perhaps, been productive of more harm than good."

Permit me to take issue upon these points, which, from the report in the JOURNAL, were all that Dr. Ferguson presented in his paper.

First. Since 1850, when I first began to operate with Dr. Wyman's fine trocar and suction pump, I have had under my care two hundred and fifty-three patients with pleuritic effusions which required operations to remove the fluid. Three hundred and ninety-five operations were done. The vast majority of these operations have been that of suction, as above named. In a certain number a permanent opening became necessary. In one, Estlander's operation of removal of portions of two ribs was performed with perfect success and complete restoration to health after four years of suffering from a fistulous opening into the chest

During this period of thirty-four years I have never met with "dangerous or fatal results consequent on the operation of suction." I have seen a case under the care of another in which a permanent opening was made *under etherization*. In this case the pulse failed twice during the operation; but full recovery to health was the final result. I believe the patient would have died if the opening had not been made.

Second. Doubtless I should have met often "with dangerous and fatal results" if I had pursued the course which Dr. Ferguson says that I recommend. Unfortunately Dr. F.'s assertion is incorrect. I do not maintain that we must draw until pain or dyspnœa occur but precisely the reverse, as my patients and students would admit. My method is as follows: I use, as at first, the finest trocar to which I have applied a suction pump. I prefer this apparatus to any "aspirator" with vacuum previously arranged, as in Dieulafoy's or any other method. I think I can by the pump, which I hold in my hand, more easily judge of the amount of force needed to extract the fluid, and can if I wish *instantly* stop all traction, whereas that knowledge is not given by the "vacuum" instruments.

Having pierced the thorax and arranged the suction, I say to the patient, "Tell me if you feel the *least* discomfort in any way, either pain or stricture or desire to cough. Tell me instantly;" and then I either wait a few moments and perhaps cautiously draw anew or I remove the trocar from the chest. I impress strongly upon the patient's mind that it is for his good to let me know the first moment of the *least discomfort*. During the operation I frequently repeat the question. By proceeding thus prudently and slowly I *never allow severe pain or dyspnœa to ensue*, and I do not recollect to have ever had "dangerous symptoms" occur.

Third. Dr. Ferguson would never take more than a pint of fluid at an operation. He would also wait before tapping "until dyspnœa or other serious symptoms" occur. Pray what would he advise in cases of *latent* effusions, when one side of the chest may be full of fluid, and the physical signs alone indicate the condition of things? His rule of delay till dangerous symptoms set in might lead either to sudden death from obstruction of the heart or to long disease, terminating fatally. Such cases I saw repeatedly before 1850. I begged medical men to operate in the cases under their charge, and they would not, leaving death as the result.

In case I find now a chest full or nearly full of fluid, even if there be no severe dyspnœa, if the patient has been ill a month or six weeks I advise tapping as the *first* remedy. I afterwards use the common remedies, internal and external, for pleurisy. Having commenced the operation I draw from one to four, or once even five, pints, always watching, especially after two pints have been drawn, the condition of the patient, as above named. It would seem to me wrong to limit myself to one pint when I could by care draw more, and thus save a second operation.

Fourth. Dr. Ferguson said also that the instrument had been used much too freely in the pelvic cavity, and has done much evil there. I am not sure that I understand aright when I say that his words seem to intimate that "on the whole" the aspirator as generally used has done "more harm than good" wherever used. If he means that assertion as applicable to the thorax, I deny it wholly. It has been of infinite service to mankind, and will ever continue to be such. It will eventually save lives which, without it, will be lost. All that is required is that due care govern the use of it.

Respectfully yours,

HENRY I. BOWDITCH, M. D.

HYDROCHLORATE OF COCAINE SUBCUTANEOUSLY.

MR. EDITOR, — As the medical journals of the country are now filled with reports of the use of the new anæsthetic, hydrochlorate of cocaine, and as the use has been more generally restricted to its application to mucous surfaces, I have thought it might be interesting to record its trial in the following case: —

Thomas H., aged fifty-five, farmer, came under observation two weeks ago. He had a peculiar ragged, ulcerated-looking patch on right cheek just below the malar bone, which was diagnosticated an epithelioma, and an immediate operation advised. As he was strongly opposed to the use of either chloroform or ether, the new anæsthetic was employed, and the operation was performed December 2d.

A four per cent. solution of the drug, a foreign preparation, obtained through the kindness of Carter, Harris, & Hawley, of Boston, was used, and the solution injected hypodermically.

The injections were conducted by Dr. J. C. How, of this city. The needle of an ordinary hypodermic syringe was passed through the skin on either side and above the growth. Four minims were employed at each injection, with an interval of from three to five minutes between each. A few minims were also rubbed over the growth with the finger. The pulse at the first injection was 88 per minute, but in five minutes after went up to 98. No change in the respiration was observed. The first injection was noticed to be quite painful, but after the second the patient remarked that the parts began to feel "numb" and "*tingled slightly*." Immediately after the third injection the cutting began. Two incisions, two inches long, were made on either side of the growth. Mr. H. remarked that the first incision hurt him no more than the ordinary scratch of a pin. The second incision was made without the slightest feeling of pain being manifested, nor was there any complaint of pain during the dissection of the growth from the muscles, which occupied from five to ten minutes, owing to delay in twisting some superficial blood-vessels. The wound was closed with hare-lip pins and the twisted and figure-of-eight sutures. Repeated questionings during this part of the operation elicited the response that he "suffered no pain." After the operation the pulse indicated 110. No headache followed, nor was there any feeling of drowsiness. An hour after the operation he complained of very severe pain about the wound, probably due to the tension of the sutures. There was no doubt in the minds of both Dr. How and myself that the injection of the cocaine rendered the operation a comparatively painless one, and was deserving of further trial and investigation.

J. F. CROSTON, M. D.

58 EMERSON ST., HAVERHILL, MASS.

— A child is reported as having recently died at Rye, England, from shock to the nervous system, caused by fright at seeing a boy wearing a mask. She lost her reason the first day after the occurrence.

Miscellany.

COMMITTEE ON ORGANIZATION OF THE NINTH INTERNATIONAL MEDICAL CONGRESS TO BE HELD IN WASHINGTON, D. C., IN 1887.

PRELIMINARY NOTICE.

THE Committee on Organization of the Ninth International Medical Congress, to be held in the United States in 1887, met in Washington, D. C., on November 29, 1884, for the determination of the general plan of the Congress, the election of officers of the committee, who will be nominated to fill the same offices in the Congress, and the consideration of questions of finance.

The following rules were adopted: —

(1.) The Congress will be composed of members of the regular medical profession who shall have inscribed their names on the register of the Congress, and shall have taken out their tickets of admission. As regards foreign members, the above conditions are the only ones which it seems at present expedient to impose.

The American members of the Congress shall be appointed by the American Medical Association, by regularly organized State and local medical societies, and also by such general organizations relating to special departments and purposes, as the American Academy of Medicine, the American Surgical Association, the American Gynecological, Ophthalmological, Otological, Laryngological, Neurological, and Dermatological Societies, and the American Public Health Association, each of the foregoing Societies being entitled to appoint one delegate for every ten of their membership.

The members of all special and subordinate committees appointed by the General Committee shall also be entitled to membership in the Congress, together with such other persons as may be specially designated by the Executive Committee.

All Societies entitled to representation are requested to elect their delegates at their last regular meeting preceding the meeting of the Congress, and to furnish the Secretary-General with a certified list of the delegates so appointed.

(2.) The work of the Congress is divided into eighteen Sections, as follows, namely: —

(1.) Medical Education, Legislation, and Registration, including methods of teaching; and buildings, apparatus, etc., connected therewith. (2.) Anatomy. (3.) Physiology. (4.) Pathology. (5.) Medicine. (6.) Surgery. (7.) Obstetrics. (8.) Gynæcology. (9.) Ophthalmology. (10.) Otology. (11.) Dermatology and Syphilis. (12.) Nervous Diseases and Psychiatry. (13.) Laryngology. (14.) Public and International Hygiene. (15.) Collective Investigation, Nomenclature, and Vital Statistics. (16.) Military and Naval Surgery and Medicine. (17.) E perimental Therapeutics and Pharmacology. (18.) Diseases of Children.

(3.) The General Meetings will be reserved for the transaction of the general business of the Congress and for addresses or communications of scientific interest more general than those given in the Sections.

(4.) Questions which have been agreed upon for discussion in the Sections shall be introduced by members previously nominated by the officers of the Section. The members who open discussions shall present a statement of the conclusions which they have formed as a basis for debate.

(5.) Notices of papers to be read in any one of the Sections, together with abstracts of the same, must be sent to the Secretary of that Section before April 30, 1887. These abstracts will be regarded as strictly confidential communications, and will not be published until the meeting of the Congress. Papers relating to questions not included in the list of subjects suggested by the officers of the various Sections will be received. Any member, after April 30th, wishing to bring forward a subject not upon the programme must give notice of his intention to the Secretary-General at least twenty-one days before the opening of the Congress. The officers of each Section shall decide as to the acceptance of any communication offered to their Section, and shall fix the time of its presentation. No communication will be received which has been already published or read before a society.

(6.) All addresses and papers, read either at General Meetings or in the Sections, are to be immediately handed to the Secretaries. The Executive Committee, after the conclusion of the Congress, shall proceed with the publication of the Transactions, and shall have full power to decide which papers shall be published, and whether in whole or in part.

(7.) The official languages are English, French, and German.

No speaker shall be allowed more than ten minutes, with the exception of readers of papers and those who introduce debates, who may occupy twenty minutes.

(8.) The rules, programmes, and abstracts of papers will be published in English, French, and German.

Each paper or address will appear in the Transactions in the language in which it was delivered by the author. The debates will be printed in English.

(9.) The officers of the General Committee on Organization are a president, three (3) vice-presidents, a secretary-general, and a treasurer, and those elected to these positions will be nominated by the General Committee to hold the same offices in the Congress. All vacancies in these offices shall be filled by election.

(10.) There shall be an Executive Committee, to be composed of the President, Secretary-General, and Treasurer of the General Committee, and of four other members, to be elected by the General Committee. The duties of the Executive Committee shall be to carry out the directions of the General Committee; to authorize such expenditures as may be necessary, and to act for the General Committee during the intervals of its sessions, reporting such action at the next meeting of the General Committee.

(11.) There shall be a Standing Committee on Finance, composed of five members, to be appointed by the President, subject to the approval of the Executive Committee.

(12.) Those who are elected as chairmen of the several Sections shall be thereby constituted members of the General Committee.

The officers elected are as follows: —

President, Dr. Austin Flint, Sr., of New York.

Vice-Presidents, Dr. Alfred Stillé, of Philadelphia; Dr. Henry I. Bowditch, of Boston; Dr. R. P. Howard, of Montreal, Canada.

Secretary-General, Dr. J. S. Billings, U. S. Army.

Treasurer, Dr. J. M. Browne, U. S. Navy.

Members of the Executive Committee (in addition to

the President, Secretary-General, and Treasurer), Dr. I. Minis Hays, of Philadelphia; Dr. A. Jacobi, of New York; Dr. Christopher Johnston, of Baltimore; Dr. S. C. Busey, of Washington.

The Executive Committee will proceed at once to complete the work of organization.

J. S. BILLINGS, *Secretary-General.*

WASHINGTON, D. C., *December* 1, 1884.

SUBNORMAL TEMPERATURES IN PARALYTICS.

IN an article on this subject by Professor Hitzig (*Berlin klin. Wochenschr.*, 34, 1884), the writer says that excessive drops in temperature take place most frequently in paralysis and the various forms of disease allied to it, especially senile psychoses. An increased giving off of heat is not necessarily present in such cases, but is always indicated if the subnormal temperature is found in other forms of mental disturbance. Not seldom there is a peculiar relation of this symptom to the paralytic affections. The lowering of temperature may precede them by hours or days, and in such cases may be considered as in a certain degree a precursor of them. In one series of cases the temperature does not come up again during the attack to the normal point; in another series it rises with greater or less oscillations to a higher or lower point, then either to return to the normal, or to remain high till death, or to sink anew. But great oscillations in temperature may come without convulsions or paralytic attacks. Such a variation occurred in the last weeks of a decrepit paralytic, between 31.6° and 37.2° C. A satisfactory explanation of these phenomena cannot as yet be given from the material at hand. In one class of cases cardiac weakness plays a leading part, but proof is yet wanting that that condition is not oftener the result of the refrigeration. The assumption of a primary excessive elimination of heat is inadequate because in two of the observations recorded and illustrated with temperature curves, intercurrent elevations of temperature took place. Under these circumstances we cannot lose sight of the possibility of a causal affection of the heat regulating centre, even if we must also admit that palpable anatomical alterations of the central nervous system, which might be reasonably advanced in explanation, have not as yet been established by any one. The experimental studies on the influence of the cerebrum upon heat production are as yet insufficient to throw light upon these questions.

REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 29, 1884.

Deaths reported 2667: under five years of age, 945; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 515, lung diseases 407, consumption 381, diphtheria and croup 214, typhoid fever 70, diarrhœal diseases 59, scarlet fever 44, malarial fevers 39, measles 35, whooping-cough 27, cerebro-spinal meningitis 14, erysipelas 10, puerperal fever seven, typhoid fever three. From *malarial fevers*, New York 16, New Orleans seven, Chicago six, St. Louis five, Brooklyn and Baltimore two each, Philadelphia one. From *measles*, New York 24, Chicago four, Philadelphia and Cincinnati two each, Brooklyn, New Bedford, and Gloucester one each. From *scarlet fever*, New York 15, Chicago seven, St. Louis six, Philadelphia four, Providence three, Brooklyn, Boston, and Baltimore two each, Cambridge, Lawrence, and Holyoke one each. From *whooping-cough*, New York seven, Philadelphia, Chicago, and New Orleans four each, Providence three, Brooklyn and Boston two each, Gloucester one. From *erysipelas*, Brooklyn three, New Orleans two, New York, Philadelphia, Chicago, Boston, and Providence one each. From *puerperal fever*, New York and Brooklyn two each, Cincinnati, Worcester, and Holyoke one each. From *typhus fever*, New Orleans two, Charleston one.

Cases reported in Boston: scarlet fever 57, diphtheria 36, typhoid fever 24, and measles 22.

In 104 cities and towns of Massachusetts, with an estimated population of 1,274,963 (estimated population of the State 1,955,104), the total death-rate for the week was 18.92 against 15.60 and 18.08 for the previous two weeks.

For the week ending November 15th, in the Swiss cities, there were 21 deaths from lung diseases, consumption, 19, diarrhœal diseases 13, diphtheria and croup four, scarlet fever two, whooping-cough two, typhoid fever two, erysipelas one. The death-rates were, at Geneva 16.3; Zurich 19.7; Basle 6.2; Berne 18.9.

The meteorological record for the week ending November 29th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the U. S. Signal Corps: —

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM NOVEMBER 29, 1884, TO DECEMBER 5, 1884.

GRAY, CHAS. C., major and surgeon (retired), died at Geneva N. Y., November 26, 1884.

KNEEDLER, WM. L., first lieutenant and assistant surgeon. Relieved from duty at Fort A. Lincoln, D. T., and ordered to Camp Poplar River, M. T. S. O. 140, Department of Dakota, November 25, 1884.

MCCAW, W. D., first lieutenant and assistant surgeon. Relieved from duty at Fort Wingate, N. M., and ordered to Fort Lyon, Col. S. O. 228, Department of Missouri, November 26, 1884.

PILCHER, JAMES E., first lieutenant and assistant surgeon. To be relieved from duty at Camp Poplar River, M. T., and ordered to Fort A. Lincoln, D. T. S. O. 140, Department of Dakota, November 25, 1884.

DEATH.

Died at Roxbury (Boston), Mass., December 7, 1884, Henry Austin Martin, M. D., M. M. S. S., aged sixty years, five months.

SUFFOLK DISTRICT MEDICAL SOCIETY. *Obstetric and Gynæcological Section.* — There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, December 17th, at 7.45 o'clock. Communications: Dr. Z. B. Adams, of Framingham, will, by invitation, read a paper entitled Objections to the Routine Practice of the Vaginal Douche after Normal Labor, following which Dr. W. S. Brown, of Stoneham, also by invitation, will read a paper entitled Forty Years' Experience in Obstetrics, including a criticism of Modern Methods, Anæsthetics, Instrumental Labors, etc. All members of the Massachusetts Medical Society will be welcome at the meetings of this Section, and are invited to take part in the discussions

JAMES R. CHADWICK, M. D., *Chairman.*
ROBERT B. DIXON, M. D., *Secretary.*

APPARENT AND REAL AMAUROSIS.[1]

BY HENRY W. WILLIAMS, A. M., M. D.,
Professor of Ophthalmology in Harvard University.

THE importance of distinguishing between certain forms of supposed, and cases of genuine amaurosis, may excuse my offering to the Society a few brief illustrations of conditions in which amaurotic symptoms may either be feigned, or where, being actually temporarily present, they depend on disturbances of circulation or nutrition in the retina or optic nerve, arising from various causes, and allowing hope of recovery; as contrasted with cases of absolute amaurosis in which structural changes, resulting from direct or indirect injury or from antecedent disease of the cerebro-spinal system, render treatment useless.

CASE I. Mrs. ——, aged thirty, was brought to me by her physician in December, 1874, with a report that four months previously she had become suddenly blind, and had since then been unable to distinguish day from night; and that, moreover, she had constant intense photophobia and mydriasis.

Her eyes were closely covered with thick black bandages, and she strongly resisted all attempts to open them; but with much effort her physician was able to keep the lids raised sufficiently to allow of my making an ophthalmoscopic examination, which disclosed no morbid appearances. Nor could any abnormal conditions be discovered by external inspection. No dilatation of the pupils was observable, and they contracted readily under the stimulus of light. Although the lady professed to be utterly blind, I thought I detected at some instants a watching and furtive following of my movements. Her physician told me that she had had severe headaches, especially at the menstrual periods, which sometimes terminated in fits amounting almost to insanity, and requiring that she should be held. These fits sometimes passed off almost instantaneously.

The opinion I gave was, that the symptoms were hysterical manifestations; the asserted blindness not being indicated by any existing appearances, and the photophobia being perhaps at first feigned, and afterwards very possibly created by artificially induced mydriasis, and increased by voluntary and long-continued seclusion from light.

Tonics and antispasmodics, with insignificant mild local treatment, together with gradual habituation to more and more light, were advised; and an encouraging prognosis was given.

Seven years later I again saw her physician, who informed me that at the consultation he had considered me mistaken in my diagnosis; but this had proved accurate, and complete recovery of the patient had gradually taken place.

CASE II. In another similar case, seen in consultation with a physician in a neighboring town, sudden and absolute blindness was said to have occurred in a young lady. Her pupils were found to act sluggishly, but no external or internal evidence of disease of the eyes or brain was perceptible. Her simulation was, however, so perfect that we were unable during the examination to gain evidence of her perception of objects: but abundant proof of this was obtained later in the case, and whilst she pretended to be unable to distinguish day from night. Under tonic and expectant treatment the predicted gradual recovery ensued; but the hysterical temperament was marked, and the same game of imposition was repeated some time afterward at another place of residence.

CASE III. Miss ——, aged fifteen, consulted me on November 28th on account of a decline in vision occurring three weeks previously after a copious epistaxis followed by headache. A second hæmorrhage of less amount took place some days later. As she said, all objects appeared indistinct, and she had vision of only $\frac{1}{200}$ for reading; yet she could tell time by a clock at some distance. Vision was not improved by glasses. The visual field was limited towards the left side in both eyes. Color perception good. Action of pupils normal. No abnormal changes were discoverable with the ophthalmoscope. There was less than the usual amount of choroidal pigmentation; so that the vasa vorticosa were clearly visible. The general condition of the patient seemed to be good, but she had grown with extraordinary rapidity during the past year, which fact, with the considerable loss of blood, might allow of a diagnosis of anæmic amblyopia, as the cause of the lessened visual power apparently existing.

CASE IV. In May, 1884, Miss ——, after copious menorrhagia, lost the power of perceiving a gas flame with one eye, although still able to distinguish objects in the periphery of the visual field. No obvious changes in the retinal circulation, or other morbid appearances, were seen with the ophthalmoscope. Some degree of anæmia was probably present in the region of the macula lutea, causing the loss of central vision, which was entirely regained as the tone of the system was improved.

CASE V. Miss ——, aged thirty-six, was referred to me by her physician as a case of glaucoma. She gave me the following history: Nine months previously she had pain in the head and eyes, continuing two days. Belladonna was used to overcome contraction of the left pupil, but she thought its use increased the pain, and gave it up. Three weeks before I saw her, without known cause, as she says, her left pupil dilated, and has continued so. I found, however, that she could read with this eye with a glass of +4.5 dioptrics. No apparent changes could be seen with the ophthalmoscope at the fundus of either eye. The pupil contracted under the effect of myotics. The tension of globe was normal. The patient asserted that the field of vision was limited, but I was not satisfied that this was the fact. Both eyes had hypermetropia of +1. dioptric.

Tonics and moderate use of the eyes, with the application of a solution of eserine to contract the pupil, were advised. The patient continued under observation from time to time for several months; the focal power of glasses required for reading with the left eye varying at successive visits, and similar refractive conditions sometimes coexisting temporarily in the other eye. The observed symptoms might arise from mydriasis and paralysis of the ciliary muscle; but in this instance were probably induced by the stealthy use of atropia. Their factitious character was rendered probable by the entire absence of any discoverable cause of ciliary paralysis, and, especially, by the occasional temporary manifestation of similar phenomena in the other eye, as well as by the general demeanor of the patient.

CASE VI. Mr. ——, aged twenty-seven, had excel-

[1] Read before the Boston Society for Medical Improvement, December 8, 1884.

lent sight until five weeks before he consulted me in February, 1877, when the upper part, and a week later the lower part, of objects became blurred, and vision was soon after entirely lost in the right eye. About this time he had an abscess in the throat which discharged and healed. Four days before I saw him the same symptoms came on in the left eye, and at the time of his visit he only saw clearly objects held directly in front or to the nasal side of this eye. No history of specific disease was obtained. He smoked from three to six pipes of strong tobacco daily. The ophthalmoscope showed a paler optic disk and retinal arteries a little smaller than normal in the right eye; the left fundus had a normal aspect. Iodide of potassium with abstinence from tobacco were prescribed.

On March 2d his wife wrote that he had nearly lost the sight of left eye.

I saw him again May 21st. The right optic disk had a pale look, as of commencing atrophy. He could distinguish objects towards the nasal but not towards the temporal side. In the left eye there was some fullness of the retinal veins, the field of vision was not limited, and he could distinguish letters half an inch in height when held close to the eye, but had almost no distant vision.

He was directed to continue the previously prescribed treatment, and I did not again see him. A year from the time of his attack his wife told me that his vision with one eye was perfect, with the other nearly so.

The rapid onset and progress of the symptoms in this case would allow of the supposition that the abscess of the throat might have had some ætiological influence; the existence of specific causes might also be suspected; and, lastly, the symptoms might be attributed to the effects of tobacco.

CASE VII. Mr. ——, of Iowa, consulted me February 2, 1882, on account of failure of vision which began two weeks previously. He now sees at distance $\frac{20}{30}$, but cannot read with the right eye, and sees no objects with the left eye. Has suffered much from malaria. The optic disk and retinal vessels, especially of the left eye, had a rather anæmic look. I ordered Fowler's solution, tonics, change of air, and cheerful society. Six weeks later I saw him a second time, and found distant vision normal in both eyes, with an improvement in the retinal vascularity and in the aspect of the optic disks.

June 1st his vision was normal with the aid of a glass of +0.75 dioptries for reading fine print.

In this case there appeared to be some doubt whether the loss of visual power and the threatening appearances of the optic disk and of the retinal circulation of the left eye were to be ascribed to malarial influences alone, or perhaps, in part at least, to the effect of large doses of quinia.

CASE VIII. Mr. ——, aged thirty, consulted me on 26th of last January. Three weeks previously he had noticed dimness of vision in the left eye, and for a few hours could not see even a bright gas light. Three days later the symptoms had disappeared. His visual field and perceptive acuteness are now normal in this eye, and no changes can be observed at the fundus with the ophthalmoscope unless possibly a slight want of fullness in the retinal circulation.

A week before I saw him he had a similar attack in the right eye, with much pain in and around the eye, to that he was kept awake for two nights. He has now no pain around the eye, but a dull pain in the globe itself, which is increased by pressure. The tension seems to be slightly above the normal. He cannot count fingers at one foot distance with this eye, except with hesitation, and only within a small space at the upper part of the field. The pupil is sluggish and inclined to dilatation. The ophthalmoscope shows slight haziness of outline of the optic disk and marked fullness and tortuousness of the retinal veins. Iodide and bromide of potass., with ergot, were ordered. On the 4th of February he could count fingers with the right eye at all parts of the field, and the aspect of the disk was improved. April 19th he had vision of $\frac{20}{40}$ for distance, and could read No. 1 of my test-type with his right eye. The optic disk, the field of vision, and the tension of the globe had become normal, and he felt better in all respects.

There seemed to be no reason in this case to suspect that the amaurotic symptoms reported as having existed in the left eye were imaginary. The patient was an active business man, and not at all inclined to permit himself to be disabled from work. A temporary embolism of the retinal artery might be a sufficient, but would be an entirely improbable, explanation of the sudden accession of these symptoms and of their prompt relief without any treatment. The rapid recovery from the unmistakable neuritis of the right eye is noteworthy; the recuperative powers being evidently good.

CASE IX. Mrs. ——, aged twenty-eight, consulted me on October 31st last. She had always lived in a warm climate, but came to a Northern State fourteen months since. During the following winter she suffered greatly from cold, and had almost daily epistaxis, which was frequently copious. On one occasion she was carried home, after having fallen in the street and lost a large amount of blood in one of these hæmorrhages. The epistaxis still continues frequent. Since the birth of her son, three years since, her menstruation has been scanty. Last March she had a sudden attack of blindness, with only a perception of light, which was attended with severe pain in the region of the frontal sinus and in the forehead. The blindness continued for two weeks, and vision was afterwards gradually recovered. No morbid appearances can now be seen with the ophthalmoscope, and vision is normal for large objects. Her range of accommodation is slightly lessened, and she has some insufficiency of the internal recti muscles, and reads better with a convex glass of one dioptric. The exhausting hæmorrhages seem to be the only explanation of the temporary loss of vision.

In this connection it may be interesting to quote from the proceedings of the Ophthalmological Society of Great Britain at two meetings in July last, as published in the *British Medical Journal:* "Mr. Spencer Watson reported the case of a man who, after a fall of forty feet, was taken up unconscious. After swelling of the eyelids had passed off he was found to be absolutely blind, and ophthalmoscopic examination revealed engorgement of the optic disks. Loss of smell was also noticed. In a few days the sight improved, and at the end of six weeks was quite restored. The probable cause of these losses of sensory activity was a hæmorrhage in the middle and anterior fossæ."

"Mr. Nettleship read a paper on some cases in which acute inflammation seemed to take place in some small part of the optic nerve. They were characterized by

a failure of sight in one eye, often accompanied by neuralgic pain in the temple and orbit, and pain on moving the eye. The disk often becomes more or less atrophic in a few weeks. The result was variable, from complete recovery to total blindness. The failure of sight was usually at its worst in three days, except in the most severe cases; recovery when complete usually required about six weeks. Changes in the disk were by no means constant even in the worst cases. These cases had to be distinguished from embolism of the central artery of the retina, from progressive atrophy where one disk was affected before the other, and from uniocular neuritis due to disease of the corresponding lobe of the brain. In some of the cases the symptoms might be explained by a periostitis of the optic canal; in others the mischief could not have been so far back; in some a rheumatic origin seemed probable. The majority of the patients were between twenty-five and thirty. At least five of the twenty-four had had syphilis, and there was a good probability of it in six others. In four cases the affected eye became permanently blind; in eight, more or less damage was done; twelve, exactly one half, recovered."

"The president, Mr. Hutchinson, had seen one case of this class, a young lady with a marked arthritic history. One eye only was affected, and became quite blind. Subsequently there was a slight papilitis. The patient ultimately recovered almost completely. Three years later she had a threatening of the same condition in the other eye, but recovered completely."

I will not cite here in detail the not unfrequent cases where amaurotic symptoms are present, often in a high degree, in tobacco consumers, but quote a brief extract from the *British Medical Journal* for June 21st, which contains a report, by Dr. Charles Shears, of "forty cases of men suffering from loss of vision, which was, probably, due to the abuse of tobacco, who were treated at the Liverpool Eye and Ear Infirmary during ten months." "Of the forty cases fourteen recovered completely; fourteen improved greatly; of nine the subsequent history could not be traced because of non-attendance. In the three remaining cases no improvement took place after attending the hospital a reasonable time. Of these three cases two would not diminish their smoking; the third was a confirmed drunkard, and was afterward attacked with alcoholic paraplegia. In twenty of the cases no ophthalmoscopic appearances were found; in eighteen the disks were pale; in two they were hyperæmic. The failure of vision is usually rapid and very marked. This leads the patients to seek early advice, which may, possibly, explain why so few cases of genuine atrophy have been reported. In many instances the state of the disk greatly resembled that met with in tabes dorsalis.

It is usually the practice to give strychnia internally. This was done in twenty-eight cases, but patients seemed to make an equally good recovery where smoking was diminished alone.

As in cases of tobacco-poisoning, so also we find that the amaurosis produced by the prolonged administration of quinia in large doses is sometimes followed by atrophy of the optic disk and occlusion of the retinal vessels, whilst that arising from malarial poisoning tends rather to induce similar changes to those observed in the eye as an accompaniment of Bright's disease. Yet in all these conditions we hope, by removal or neutralization of the pernicious agencies before the structural alterations have gone too far, to obtain a favorable termination. Instances of temporary loss of vision accompanying diabetes or coexistent with albuminuria during the puerperal state, or occurring after flooding, will, naturally, suggest themselves to the practitioner as also tending to a fortunate result without local treatment being required. I reported in May, 1875, a remarkable instance of amaurosis with nystagmus, in a girl of eight years, occasioned by the presence of tape-worm in the digestive organs, which was relieved, after having continued several weeks, upon the expulsion of a large amount of tenia, which was effected by the use of anthelmintics.

We have seen that the retina and optic nerve have this resemblance to the brain, that they may be the seat of intermissions of function depending on disturbances of circulation or nutrition without the establishment of serious pathological alterations. Many of these cases of disorder of function have a special interest for the general practitioner, possessing, as they so often do, a diagnostic value in relation to conditions of the general system which have given rise to them, and requiring tonic, alterative, specific, or antimalarial treatment for their relief. Quite different are those other conditions of true amaurosis with atrophy of the optic nerve, resulting either directly from injury, from embolism of the retinal artery, from obliteration of the retinal vessels caused by phlegmonous retro-bulbar inflammation within the orbital cavity, or from disease of the cerebro-spinal system, where absolute structural changes render the prognosis entirely unfavorable and all treatment ineffective. Here much harm may be done by the use of too active remedial means.

Althaus, in his new work on Sclerosis of the Spinal Cord, says, "As I have found the general effects of strychnia injurious in tabes I would strongly dissuade practitioners from resorting to this drug whether for optic atrophy or other symptoms." Michel, of Wurzburg, testifies to the same effect: "The formerly highly recommended injections of strychnia have proved to be useless." He has a similar opinion as to the value of local depletion, of which he says, "The still very popular abstraction of blood from the temples by means of artificial leeches are to be regarded as useless, especially in inflammations of the iris and the ciliary body. If improvement of vision is observed soon after the depletion it is to be attributed either to the quiet of mind and body together with staying in a darkened room, which are usually advised after the abstraction of the blood, or the improvement depended on the nature of the disease." And again, in speaking of the treatment of myopia complicated with posterior staphyloma, he says, "Depletion from the temporal region is still frequently recommended, but I have been unable to convince myself of its value."

How a seemingly trifling lesion may cause loss of vision and subsequent atrophy from compression of the optic nerve will appear from the following case, which I will cite as an example of its class: —

A boy, ten years old, was brought to me on the 19th of September last. Three days previously he fell three or four feet from a fence, and, as he thinks, struck a projecting twig of a hedge, causing a small wound of lower lid near the inner canthus. There was a small ecchymosis of the ocular conjunctiva behind the situation of the wound of the skin of the eyelid, and a slight ecchymosis beneath the skin of both the upper and lower eyelids near the outer canthus. No other change was observable in the eyeball either upon ex-

ternal inspection or ophthalmoscopic examination, but there was no perception of light with the injured eye.

After the fall he went into the house where he was passing the afternoon, complained of faintness, said he thought he had lost his eye, vomited his dinner, and then went to sleep for an hour at least. At about five o'clock he rode a mile and a half to his home, and went at once to bed without eating. At the end of an hour he woke and complained of his head, as he had done when he first reached home. During the night he woke several times and said he had headache. He was in bed the whole of the next day, and seemed rather dull and heavy. The following day he was in bed, with the exception of two hours, but ate a fair amount of light food. When brought to me, after a twenty miles' journey, he seemed in good health and spirits. His pupil had been dilated by atropia by his physician. Bromide of potassium and quiet were advised. A week later the wound of lid was healed, and the ecchymoses had disappeared. On October 4th a small scar of the lower lid was the only obvious trace of the injury; a slight divergence of the eye observed at the first visit was scarcely noticeable. The movements of the pupil were sluggish, but there was no mydriasis. There was no evident change at the fundus of the eye, but the absence of light perception continued. A small fracture of the wall of the orbit or of the parietes of the optic foramen may have caused pressure of a bony fragment upon the nerve, but thus far no visible change had taken place in the circulation in the retinal vessels which penetrate the nerve within the orbital cavity, nor did the nerve itself show signs of the compression which had abolished its function of conveying impressions to the brain.

SOME POINTS REGARDING PUERPERAL CONVULSIONS, ILLUSTRATED BY TWO CASES.

BY CHARLES F. WITHINGTON, M. D.

THAT the unexpected is what happens in the matter of puerperal convulsions is a fact that must have presented itself to most practitioners. Eclampsia sometimes occurs when least looked for, and again when all rules teach us to expect it, it fails to appear. The following two cases seem to the writer of interest as bearing upon our means for predicting convulsions. To be forewarned is to be forearmed, and where so much depends upon prompt action it is obviously of great importance to be able to recognize every danger signal which nature puts up. When in spite of the danger signal the catastrophe does not occur, it does not necessarily show that the signal was a lying one, but rather that there has been some compensatory action of nature opposing and countervailing a danger which in itself was nevertheless real, and of which the sign we saw was no false witness.

CASE I. Mrs. B., age thirty-six, quintipara. The patient is a blonde, of plethoric habit, and of nervous temperament. Previous labors rapid and easy. When five months pregnant with her last child she had scarlet fever, one of her children at the same time dying of the disease. There was some dropsy following. As she lived at the time in another city the condition of the urine is unknown to the writer. This labor occurred some four or five years ago. The child was healthy, but died at the age of about ten months of a diarrhœal disease. In January, 1883, and following, the patient was under my care for debility, accompanied by severe cephalalgia. The pain sometimes appeared to be neuralgic and again was evidently intracranial. Neuralgic attacks in other parts of the body, notably the ovaries, were observed during the winter, which she said she had suffered from before. Examination of urine showed it to be normal. Her condition gradually improved, and she spent the summer of 1883 in Europe with benefit. Conception took place at about the time of her return in the fall.

Throughout the pregnancy the patient was miserable. Most of the time the lips were markedly purple. Dyspnœa and palpitation occurred on slight exertion. In the early months nausea and vomiting were rather troublesome, but stopped at the usual time. There was excessive œdema of the feet, also moderate œdema of hands and face. The left hand in particular felt numb, and partially devoid of sensation. Cyanosis under the nails. Headaches and flitting neuralgic pains were frequent. A sharp attack of sciatica at one time prevented her from walking. The bowels tended to constipation, but were kept regular by daily use of Hunyadi water. Appetite poor. Patient says she never felt nearly as bad in any previous pregnancy. Weeps easily and is depressed. The heart was examined two or three times and nothing abnormal detected. The urine, which was good in quantity and normal in density, contained no albumen until May 30th, when a very faint trace was discovered. But nothing abnormal appeared in the sediment at that time.

The expected date of confinement was June 26th. On May 30th there was an attack of epigastric pain, quite severe, and the urine was examined with the result given above. For the next ten days the patient continued to be on her feet somewhat, as she had been before, though for several weeks she had hardly been out of doors, feeling quite unable to walk from weakness and dyspnœa. Several endeavors to administer iron failed on account of its disagreeing. The same ill-success attended attempts to employ digitalis.

June 11th there was another exacerbation of symptoms; headache, and epigastric pain very severe. Nausea, no appetite, great lassitude, and some but not excessive mental depression. Sight unaffected. Considerable œdema of hands and feet. The urine, which was learned to have been diminished for the last few days, was measured and found to be twenty-two ounces for the twenty-four hours. Micturition rather frequent. Color high. Albumen one fourth per cent. Sediment uric acid crystals, a little blood, free renal epithelium and pavement epithelium, hyaline casts, some of which had whole renal cells adherent. From this time on the patient was kept constantly recumbent, and was given diuretics, dry cups over the kidneys, etc.

June 12th. The amount of albumen was much increased, amounting to about one per cent. The sediment as yesterday, but all the abnormal constituents, especially the hyaline and granular casts, were more abundant. Dr. W. L. Richardson saw the patient with me to-day in consultation with reference to the induction of premature labor, in view of the seeming danger of convulsions. Meantime the amount of urine for twenty-four hours had increased to thirty ounces. Although the cephalic and epigastric pain continued to be severe, yet in the absence of other imminent symptoms it was considered advisable to maintain an attitude of armed expectancy rather than to

terminate the pregnancy, on the ground that should convulsions occur, the same proceeding which was now under contemplation could be resorted to, with an assurance, then, that it was necessary and was not itself the cause of the convulsions, as might possibly be suspected if labor were induced now. Moreover in the remaining two weeks a constant maintenance of the recumbent posture might, by relaxing the tension on the renal vessels, effect such an improvement in the condition of the kidneys that the risk of convulsions would be materially diminished by the time labor set in. The last diminution in the amount of urine having occurred while the patient was taking digitalis, it was considered unadvisable to resume this. She was given chloride of iron in the form of a pill (Rabuteau's), with granular extract of malt, and special attention to feeding. The citrate of potash, which was given yesterday, was continued, as also the dry cups daily.

Our anticipations were realized. The urine increased daily for the following week, reaching fifty ounces and over. The albumen diminished greatly, and the casts became less frequent, though they were still present. The epigastric pain diminished, and she was quite comfortable when the labor came on a week later (June 19th). The only abnormality about the labor was a low attachment of the placenta which gave rise to quite sharp hæmorrhage during the stage of dilatation; so much so that the patient fainted and the pains died away. Considerable anxiety was felt, but after turning out three handfuls of clots from the vagina, a Barnes's bag (largest size) introduced into the os checked the bleeding and brought back the pains. As the head came past the edge of the placenta the hæmorrhage stopped while the bag was expelled. With the placenta after the birth came away a clot as big as the fist, which doubtless was formed *ante partum*.

The convalescence was favorable, but on the second day another severe attack of gastralgia occurred. The urine remained abundant, and an examination of it soon after the ceasing of the lochial discharge showed but a faint trace of albumen and no abnormal renal elements. Later, the albumen disappeared.

The questions of interest in this case are these: How imminent was the danger of convulsions at the time when the renal disturbance was at its maximum? What circumstances, if any, would have precipitated an eclamptic attack? What would have been the effect of an operation for the induction of premature labor at that juncture? What effect, if any, was produced upon the risk of convulsions by the free hæmorrhage which occurred during the first stage of the labor? What was the significance of the symptom of epigastric pain?

The answer to most of these inquiries can, of course, only be conjectural, as must be the case with all questions having reference to conditions that were not fulfilled. Regarding the actuality of the danger, we can only say that those renal conditions were undoubtedly present, which are generally admitted to be the prodromata of the great majority of cases of convulsions. We do not at present concern ourselves with the different theories of the pathology of this affection. But whether the convulsions are due to uræmia, hydræmia, or cerebral anæmia, the renal conditions indicated by albuminuria and casts undoubtedly do favor the occurrence of eclampsia. Braun found that sixty per cent. of the cases of acute and chronic nephritis together developed convulsions. Hofmeier reports 104 cases of convulsions in 137 of nephritis. Moreover the acute forms of renal disease are more likely to give rise to eclampsia than the chronic.

It seems reasonable to suppose that inasmuch as the renal trouble and the significant symptoms had developed progressively during the time while the patient had been on her feet, and as after she was put to bed the improvement began, it was at least as much owing to recumbency as to medication, and that had she kept about the house an attack might have been precipitated. Moreover, as we know that sixty per cent. of the whole number of convulsions occur during labor itself, it seems not improbable that had labor come on either naturally or artificially during that period when the kidneys were most disturbed in their action convulsions might have occurred.

Whatever may be the effect of venesection in eclampsia, the same probably would be that of a free uterine hæmorrhage. I believe that in this case with the mitigation of the symptoms the immediate danger of convulsions had largely passed away at the time labor occurred. But the persistence of a moderate albuminuria and the fact that the supposed cause of the renal disturbance, namely, the pregnancy, still existed make it possible that there was still some danger. Testimony is tolerably unanimous that at least the primary effect of venesection is favorable in eclamptic cases by reducing the blood pressure. Even though the pressure should soon come up again with an additional degree of hydræmia from the bleeding, yet something would have been gained temporarily, which, with the subsequent removal of the exciting cause, might leave a definite gain to the credit of the venesection. All this may equally be said of a hæmorrhage, accidental or unavoidable. It may be of interest in this connection to remember that post-partum hæmorrhage is an especially frequent occurrence in conjunction with eclampsia.[1] Whether this is to be taken as a natural attempt at therapeusis we venture no opinion.

In a paper by Dr. Goss, read before the Boston Society for Medical Improvement,[2] special attention is called to severe epigastric pain as a precursor of eclampsia. In the discussion that ensued several instances of this symptom were referred to both with and without convulsions. In the latter case the urine was albuminous and contained casts. In Leishman's System of Midwifery epigastric pain is given as one of the three cardinal symptoms of impending convulsions. Now in my patient, although the attack of June 11th was by far the severest one she ever had had, yet gastralgia, in no way differing, except in degree, from that attack, had, in common with other neuralgic manifestations, occurred to her from time to time before, and has once or twice since the labor, having a marked connection with fatigue and worry. So that I do not feel sure that this pain had any distinctive relation to her albuminuric condition. As a marked instance of such a relation, however, I will cite the following: —

Case II. Mrs. D., aged twenty-eight, secundipara, brunette, of full habit. Kindly referred to me by Dr. Sumner. The date of confinement was uncertain. Catamenia last November 5, 1883, but patient says in her previous pregnancy she menstruated once or twice after conception, and she is confident from personal data that in this instance pregnancy could not have begun

[1] Lusk's Science and Art of Midwifery, p. 528.

[2] Boston Medical and Surgical Journal, November 13, 1884.

later than the end of September. Condition good during the early part of pregnancy. At about April a swelling of the veins of the left labium began, which increased gradually to the size of a hen's egg, disappearing when she was recumbent. She expected her confinement about July 4th, and had her nurse in the house from that time on. From that date she became considerably worried, thinking she was going so much over her time, from which opinion she could not be persuaded. She had first felt motion about March 13th, and my estimate of her time of labor was from the 11th to the 15th of August. After the beginning of June she remained indoors almost altogether, avoiding walking on account of the varix as well as of swelling of the feet and hands, which was considerable. Says also that her face is much altered, though no well-marked œdema is observed there. The discomfort was no greater than was to be expected from her advanced pregnancy. August 14th, the œdema being considerable, I examined the urine and found it abundant in quantity, with a questionable trace of albumen, but no casts.

On the evening of August 19th her husband called to say that she was complaining of intense pain at the pit of the stomach. I prescribed for her, but did not visit her until the following morning. On that day the pain at the stomach still continued, and there was slight headache, but no impairment of vision. Œdema not excessive even in feet. There was some nausea but no vomiting. No especial mental depression. I advised her to stay in bed for the most part during the rest of her pregnancy. While sitting in a chair at five P. M. of this day she complained suddenly of her head feeling very bad, and had a convulsion. I was sent for at once, but was absent from home. At 5.30 she had a second convulsion. My neighbor, Dr. J. S. Flint, was then called, and arrived at six o'clock, just in time to witness a third convulsion. On my arrival, at 6.15, I found the patient unconscious in a state of coma, from which she soon partially emerged. The condition of the os showed labor to have begun. A subcutaneous injection of four minims of Magendie's solution had been made at six o'clock, and this was now followed by ten grains of chloral, the patient being able to swallow. Dr. Flint, at my request, kindly remained till the labor was completed, and gave me valuable assistance in the management of the case. At 7.30 o'clock occurred the first convulsion after my arrival (the fourth in all). Ether was administered during this seizure, and in the succeeding stage of unconsciousness, from which she did not emerge before the next attack, manual dilatation of the os was performed. In course of an hour the os was expanded from the size of perhaps two centimetres to five centimetres. Then as more active pains were coming on we waited to see what they would accomplish. At 8.30 a fifth convulsion occurred. Ether was then continued after the seizure ceased, and the forceps applied at the brim. Locking was effected with some difficulty, and traction made gradually and continuously. At 9.30 o'clock a male child, weighing eight and one half pounds, was delivered without perineal rupture. The placenta not following within fifteen minutes, and there being little uterine action, I introduced my hand and scraped it off. It was remarkably large, but otherwise normal. Respiration did not become established in the child for some fifteen or twenty minutes, but afterwards went on properly.

The patient lay mostly unconscious until two the next morning, when a sixth convulsion occurred. She was given chloral by rectum, and one fourth grain of Magendie's solution, followed, as soon as she could swallow, by one fourth grain elaterium. This was repeated twice (in all three fourths grain) at intervals of two hours, and produced free catharsis. The seventh and last convulsion occurred at six A. M. She was made to swallow a mixture of the citrate and acetate of potash in frequent doses, and dry cups were applied to the loins. She regained her consciousness in a measure in the afternoon of this day, and was very peevish and irritable. She also passed urine in good quantities. Unfortunately the urine which I drew at the time of applying the forceps was thrown away by the nurse, and no more could be obtained free from admixture with lochial discharge. From the testimony of the nurse it is pretty certain that during the afternoon and night of the convulsions the urine was greatly diminished in amount. After she fairly regained consciousness she was unable to micturate, and the urine had to be drawn by catheter until she was able to sit on a vessel. The convalescence was uninterrupted and normal in every respect. Her recollection of the occurrences for about twenty-four hours from the time of the first convulsion was altogether wanting, and, as she afterwards said, she was not herself for several weeks. For instance, on attempting to write, she found herself unable to spell common words, and on trying to look them up could not find them in the dictionary. Her conversation seemed to her friends strange, and she was conscious that she acted and talked queerly, apologizing after she had quite regained her natural self for what she thought she might have said "wrong" during the few weeks after her labor.

In this case the epigastric pain was very marked, being by far the most noticeable precursor of the convulsions. Had I been aware then of the significance of this symptom, I should have been led to make another examination of the urine, which would, probably, at that time have given the evidence that a week before it failed to present of the impending catastrophe.

Regarding the treatment of convulsions, it is not my present purpose to speak. Suffice it to say that I believe the favorable result in this case was due largely to what is of primary and vital importance whenever convulsions occur before delivery, namely, the emptying of the uterus with all possible alacrity.

REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M. D., AND H. L. BURRELL, M. D.

SPINA BIFIDA.

LÖBKER[1] reports four cases operated upon by him. The first, seven weeks old, presented a tumor of the size of an apple in the lumbar region. Five grammes of the fluid of the cyst were drawn out by means of a subcutaneous syringe, and two grammes of a freshly made solution of pure iodine 0.5, iodide of potash 1.0, water 30.0 injected in, and slight compression was applied. This procedure was repeated three times at intervals of from five to eight days. Recovery followed, with shrinking of the tumor, so that a year later a small tumor of the skin of the size of a silver quarter was all that

[1] Centralblatt f. Chirurgie, No. 33, 1884, p. 539.

remained. A year and a half later the child was reported as well.

A second case was operated upon twice when from eleven to twelve weeks old. The interference was well borne and the tumor became smaller, but further treatment was discontinued, and the child subsequently died. The third child was five days old, the tumor was in the lumbar region. The pedicle was tied by two ligatures, the sac cut off, and the wound dressed with iodoform gauze. The child is reported to have been discharged well. A fourth case was that of a child four months old, with hydrocephalus. Death resulted from ligature and extirpation.

Löbker advises insertion of the needle of the subcutaneous syringe into the base of the swelling, and compression of the base so that the iodine should not enter the canal.

A child [1] aged two months, female, had a tumor the size of a peach in the middle line, opposite the two last cervical vertebræ. It had a pedicle an inch and a half in circumference. The tumor was soft and fluctuating; under strong pressure it diminished in size, causing the child to cry and have slight convulsive movements of the limbs. The tumor was half emptied of a thin, transparent liquid of alkaline reaction. The pedicle was constricted by a couple of turns of elastic ligature. At the moment of constriction the child cried, became livid, and some clonic movements were excited, but in a few hours these subsided.

On the sixth day there was vomiting, a tendency to coma, and twitching of the upper limbs, but after this they did not return. The ligature separated on the twelfth day.

NATURE OF RICKETS.

Korsakow — in his inaugural thesis at Moscow — considers the following questions: —

(1.) Whether a diet poor in lime salts in young animals produces changes in the bones analogous to rickets? (2.) What influence phosphoric acid and carbonate of lime will have added to this diet? (3.) What influence lactic acid has upon the bones of young animals?

In endeavoring to find an answer the writer instituted a series of experiments upon growing animals with the following results: —

Changes in the structure of bone similar to those observed in rickets in man were produced by food poor in lime salts, which changes can be prevented by the addition of a sufficient quantity of phosphate of lime. These changes also result when a diet rich in lime salts is administered if the lime salts are not properly absorbed by the digestive apparatus. Lactic acid did not produce any rachitic changes, but small doses of phosphorus, and also of strontium combined with improper diet, will produce such changes.[2]

FLAT FOOT.

According to Henke, the primary cause of the distortion of valgus is a relative weakness of the tibialis posticus which allows the abnormal pronation of the front of the foot; secondary alterations take place in the shape of the bones from the altered pressure. H. v. Meyer agrees in the main with this view, believing that the arch of the foot is laid upon its side, but not broken, and in confirmation of this view found that the calcaneo-scaphoid plantar ligament was not lengthened. Lorenz [3] explains the deformity in much the same way. The foot practically consists of two arches or trusses, an outer and an inner. When weight falls upon the foot a slight pronation occurs, and the inner truss in a measure slides on the outer. If the weight is greater than the foot can sustain the outer truss is flattened, the astragalus twisting on its transverse axis, and the inner truss falls to the inner side. Irritation of the joints follows, and contraction of the muscles takes place.

Terrillon [4] found on examining three persons with acquired flat foot, with pain and tenderness, a paresis of the peronei and tibialis anticus.

Verneuil distinguishes three classes of this trouble: in the first a contraction of the peronei is the primary trouble; in the second paralysis of the tibiales muscles; the third, an arthritis of the tarsus.

Despres considers that there are three stages of the trouble: first, a paresis with slight flattening of the arch of the foot, with occasional contracture of the extensors; second, flattening, with a contraction of all of the muscles of the feet; and third, contraction, with alteration of the bones. The only rational treatment consists in the application of electricity and the employment of an apparatus which holds the foot in the proper position.

THE PATHOLOGY OF CLUB-FOOT.

Mr. R. W. Parker and Mr. Shattock [5] have completed their paper advocating the mechanical mode of causation of this deformity. Their opinion rests on the careful dissection of five cases (three varus and two calcaneus) and on a study of the various specimens in the London museums.

The contention was that there was nothing especial in this deformity, and nothing which might not occur in other joints. In one of the cases there was histological integrity of the affected limb, but there was some extra obliquity in the neck of the astragalus. In another case, however, there was no such malformation of the astragalus. Hence they argued the insufficiency of the usually accepted theories, nerve lesion or bone deformity.

It was shown that the conformation of the astragalus which ordinarily exists in talipes is the normal condition of simiadæ, and these animals are not talipedic.

As proofs of pressure in new-born children, instances of torsion of bones of the leg and of the astragalus were referred to, also a case where depressed patches of atrophied skin, with bursæ existing, were found over the external malleolus and over the head of the astragalus like those found in persons who had walked on an unreduced talipedic foot. The varieties of varus and calcaneus were thought to depend on the date of onset, and to be in both cases an exaggeration of normal positions at some time in fœtal life.

EXCISION OF TENDO-ACHILLIS IN TALIPES CALCANEUS.

Mr. Walsham [7] has excised from one half to two thirds of an inch of the lower end of the tendo-Achillis in four cases of talipes calcaneus. The section of the tendon was made obliquely from above downward, and before backwards, and the divided ends were united

7 British Medical Journal, June 14th.

by kangaroo tendons. All were improved. Two regained the power of flexion and extension of the foot.

RESECTION OF MUSCLES IN INFANTILE PARALYSIS.

Mr. Keetly [1] has recently undertaken the resection of part of the quadriceps extensor femoris in a case of infantile paralysis causing inability to extend the right knee. A longitudinal incision was made in front of the thigh about three inches in length, and extending an inch above the patella. The skin was held apart by retractors, and an inch of the entire substance of the muscle was removed with scissors about two inches above the patella. A dozen carbolized catgut ligatures were used to unite the two ends. Esmarch's bandage had been applied before the operation, and only one small artery required ligation. The wound was dressed with an iodoform pad and antiseptic gauze. A splint was applied which made an angle of sixty degrees with the bed.

Mr. Willett has [2] already resected the tendo-Achillis in paralytic calcaneus with good results. He found that the shortening of abnormally elongated tendons enable the muscles of the calf to regain some portion of their lost functions.

TREATMENT OF CHRONIC AFFECTIONS OF THE JOINT OF THE LOWER EXTREMITY.

Caumont [3] generalizes on the cases of disease of the hip, knee, and ankle observed in the hospital at Münsterling between the years 1871 and 1881, 212 in all (and sixty-nine resections).

Of the eighty-five cases of disease of the hip-joint which did not undergo resection the result was the better the earlier the cases came under treatment. For example, of eleven patients treated from the earliest stage nine recovered perfectly, while of twenty cases in which treatment began in the stage of inflammation fourteen recovered and four died. Of the thirty-nine cases treated first in the third stage, but without resection, only nineteen recovered with but little deformity, seventeen died, and three were but little improved. Forty-four were excised with a mortality of 61.03 per cent. Of twenty severe cases, but without marked suppuration, five died, twenty-five per cent. mortality; while of ten similar cases resected five died; a mortality of fifty per cent. Of nineteen severe cases with suppuration, treated without operative interference, a mortality of 63.01 per cent. is recorded; and of twenty-three similar cases which were resected the mortality was about the same, 63.07; while the percentage of recovery with slight deformity was somewhat greater in the excised than in the non-excised cases.

The author quotes Ollier in regard to resection: — "Les resections les moins nécessaires pour la conservation de la vie sont celles qui donneront les résultats les plus brilliants au point de vue de la reconstitution d'une articulation nouvelle."

Of the knee-joint the mortality in ten cases (without suppuration) and not resected was ten per cent; fifty per cent. recovered; forty per cent. lived, but with a limb of little use, and of these one underwent amputation. Three similar cases submitted to excision. Two recovered with useful limbs; one recovered after amputation. Twenty-five suppurative cases gave a mortality after expectant treatment of sixty-four per cent.; thirty-six per cent. recovered, but two of these cases underwent amputation. Twenty-nine suppurative cases resected gave a mortality of forty-four per cent., and four of the cases were amputated.

Nine severe cases of caries of tarsus gave the following figures: two died; two were amputated; two recovered; three did not recover. Seven cases were resected, and two of these were cured, two uncured, and three died.

(To be concluded.)

Reports of Societies.

PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

NOVEMBER 24, 1884. The PRESIDENT, DR. CHARLES D. HOMANS, in the chair.

ACRANIA AND SPINA BIFIDA.

DR. W. W. GANNETT showed a fœtus, which was of about seven months, and which presented the characteristic appearances of that form of monstrosity known as acrania, together with spina bifida. There was no appreciable neck, the ears resting upon the shoulders, and the eyes turned upwards. The cranial bones were wholly wanting, their place being occupied by a membranous sac about the size of a peach, containing thin fluid and a small amount of brain substance.

A hydrocephalus occurring early in fœtal life was the most satisfactory explanation yet advanced to account for such changes.

The spinal column was interesting from the fact that the arches of the vertebræ, together with the spinal cord, were absent.

DR. BUCKINGHAM said that the mother was a patient of Dr. George W. Gay. The interesting clinical fact, aside from delivery at seven months without obvious cause, was the difficulty in making out the presentation. There seemed to be a cross birth, but it was not possible to determine at which extremity lay the head. The fœtal heart was not to be heard. In vaginal examination, before rupture of the membranes, the finger struck upon what seemed like the extremities of fingers, or like a row of teeth; but which proved to be the union of the ribs with the vertebræ. The presentation being probably transverse, the os three quarters dilated, and the patient beginning to tire, Dr. Gay ruptured the membranes and delivered by the feet. There was a very large amount of amniotic fluid.

As the only other pregnancy had ended in abortion at three months, the question of syphilis had been carefully considered, but there was no history of syphilitic symptoms.

CYST OF THE BROAD LIGAMENT.

DR. J. W. ELLIOT showed a cyst of the broad ligament which he had removed two days before by abdominal section. The cyst was about the size of a cocoanut, and contained a pint of clear fluid. The Fallopian tube was much enlarged and coiled around the cyst. The ovary being about two inches long was also removed. Dr. Elliot had begun to shell the cyst out of the broad ligament, but when he found the tube and ovary diseased had clamped the whole broad ligament. The cyst was adherent to intestines and to mesentery.

He had succeeded in removing it through an opening of two inches in the peritonæum. In reply to questions he stated that the patient had not had a bad symptom since the operation; the temperature going only to 100° F.

DR. J. C. WHITE read a paper entitled Psoriasis — Verruca — Epithelioma; a Sequence.

Publication reserved.

THE USE OF COCAINE IN THE NOSE.

DR. F. H. HOOPER spoke of the effects of this drug in a case of acute coryza. The left nostril was completely occluded; the right only partially. The sense of smell was absent. On applying a two per cent. solution of the muriate of cocaine to the interior of the nasal cavities by means of a cotton-tipped probe, free respiration was immediately established, the sense of smell returning at the same time. The nose remained perfectly free for three hours, when it began to close up again. This was followed in about an hour by a partial reopening, but at his second visit, five hours after the first application, the left nostril was again absolutely stopped, the conditions, in fact, being the same as at the morning visit. Cocaine was again applied in the same manner, and its use was followed instantly by the same result. Both nostrils have since (two days) remained open. He had also used it in a case of chronic hypertrophy of the nasal mucous membrane with the effect of causing a very notable contraction of the swollen tissue. Dr. Bosworth[1] was the first, as far as Dr. Hooper was aware, to call attention to the use of cocaine in the nose. Dr. Bosworth supposes that it produces its effect by causing a tetanic contraction of the muscular fibres which are found surrounding the venous sinuses which form the erectile tissue of the nose.

DECEMBER 8, 1884. The President, DR. CHARLES D. HOMANS, in the chair.

HYDROCHLORATE OF COCAINE.

DR. CHARLES H. WILLIAMS stated that, assisted by his brother, he had experimented on himself with cocaine subcutaneously, taking in the arm five one half grain doses at half-hour intervals. There had been partial local anæsthesia extending a short distance up and down the arm, and to a less distance around it. The skin was tested by calipers, and seemed to have lost none of its sensitiveness except near the place of injection. In the throat, reflex spasm did not occur when the pharynx and larynx were touched by instruments. The effect of the drug passed off in about two hours, and other tests were not made on this occasion. He had also applied cocaine to the gum before allowing a tooth to be filled, but did not think it had been of any service. In his hands it had diminished pain when applied before passing the lachrymal probe.

DR. H. W. WILLIAMS had been told by a dentist of large practice that it was not of use in dental operations.

DR. WADSWORTH quoted a recent journal that a Prussian druggist had taken fourteen grains of cocaine by the mouth, then fell asleep, but waked after a time with griping pains in the stomach. There were one or two other symptoms of no great moment. No serious ill effects. He had a number of times greatly lessened the pain of probing the nasal duct, in sensitive patients, by placing two or three drops of a two per cent. solution in the conjunctival sac.

The drug was of value also for another purpose, which he had not seen referred to, for the relief of a certain form of headache. A day or two after he first obtained some of the solution a young lady came to him suffering from headache, to which she was subject. Her drooping lids and whole demeanor were characteristic of headache. The larger part of the pain was referred to the eyes, and it occurred to him to try the effect of cocaine. In a few moments after placing a drop or two on the conjunctiva of each eye the pain in the eyes was wholly relieved, the lids opened naturally, and the lady's whole appearance was changed. Pain in the top of the head and at the root of the nose was still felt, but the total amount of pain was so much lessened as to give little inconvenience. Dr. Putnam, to whom he mentioned the case, had tried the remedy in one or two instances with advantage. In one or two cases in which the pain was not especially in the eyes there was no effect.

DR. HAY said that he had excised a piece of xanthelasma from each eye, one of the pieces being five eighths of an inch long. The patient had been previously treated with cocaine, and there seemed to be little discomfort.

PNEUMO-THORAX.

DR. LYMAN presented three cases of pneumo-thorax, and said, "It is so unusual to have three cases at once and in such condition as to allow of their presentation together for comparison, that I think the Society may be glad of the opportunity to examine them. They are of interest as illustrating different varieties of the disease, one being of surgical or traumatic origin, one due to tubercular ulceration from the lung outward, and one following pleurisy, it being doubtful whether the perforation was from the lung outward or vice versa. I am indebted to Dr. Mason for the statement that in his ten years' review of the hospital records he found no case of simple pneumo-thorax, and none in which the generation of gas from pus was suspected. The probability of such a phenomenon is discredited by many writers.

"The first case (Hart) is nearly well, so that the pathognomonic phenomena, which were well pronounced, must be gathered from the hospital records. It exhibits, however, in a marked degree the resultant phenomena of a typical case of traumatic pyo-pneumothorax. The respiration, as you will see, is nearly restored, but the flattening of the chest is well marked, and owing to the large effusion of lymph the ribs remain nearly quiescent and the heart somewhat displaced. Inflation of the lungs is at the expense of the diaphragm.

"The second case (McGuire) is a typical case of hydro-pneumo-thorax from pulmonary tubercular ulceration into the pleura. The date of the perforation with its accompanying symptoms cannot be ascertained with certainty. The cause of the temporary hemiplegia is also problematical. The percussion, metallic tinkling, and splashing speak for themselves.

"The third case (McCarthy) is interesting in many aspects, especially so with regard to the prognosis. A fairly healthy boy of seventeen, whose mother died of phthisis, was while in apparent health attacked with the ordinary signs of acute pleuritis. For this he was tapped twice before entering the hospital, about three pints of serum being obtained each time, the first

[1] New York Medical Journal, November 15th.

clear, the second slightly cloudy. Ten days before entrance, and between two and three weeks after the second tapping, he states that he was *suddenly* seized while ascending the stairs with a sharp pain in the left chest, followed immediately by severe dyspnœa. Possibly there was at that time some slight rupture of the pulmonary pleura, or perhaps some slight injury to that membrane at the last tapping may have resulted in ulceration; or again, it may be one of those cases which have given rise to the belief in the secretion of air by the pleura itself. We can at any rate exclude, as cause, decomposition of the fluid; inasmuch as there was no previous empyema. However this may be, it seems probable, in view of the absence of any marked signs of pulmonary disease, that the opening was from the cavity rather than from the lung. He has had no cough or other signs of any *ulcerative or softening* process in the lungs up to the present moment. He is somewhat anæmic, and emaciated, and the presence of moist rales were reported in the early history of his disease, but nothing which is not readily explicable on the theory of pleuritis alone.

"The subsequent treatment depends on circumstances. Possibly the pulmonary orifice, if such there be, may be closed by lymph, and thus exclude one factor; but as the fluid which I removed at the third tapping, five days since, was somewhat purulent a permanent opening may soon become necessary."

CASE I. Hart, aged twenty-three, single, occupation upper cutter, entered the City Hospital in the service of Dr. G. B. Shattuck August 9, 1884. His father died of phthisis. Had pneumonia four years ago. In June last he received three stabs from a jackknife. Two of them, one in left side and one above right clavicle, were superficial, but the third penetrated the chest at the first right interspace a little inside the line of the nipple, and was followed immediately by intense dyspnœa, and soon after by rigors, pain, cough, and expectoration. At a later period a permanent opening was made by Dr. Latimer, of East Cambridge, in the tenth right interspace one and a half inches posterior to axillary line. The pus was very fetid, and the chest was washed out with some antiseptic solution. On entering he had a large bed-sore over the sacrum, and had diarrhœa; the original wound was found nearly healed, and the pus from the dependent permanent opening was very offensive. The probe entered easily inwards and upwards in a line towards the nipple. The clavicles were prominent, right ribs sunken, and with little motion. Movements of left chest exaggerated. Whole right front and back markedly tympanitic, and vocal resonance absent below angle of scapula. Percussion somewhat dull below sixth rib in left axilla and outer part below angle of scapula. Resonance exaggerated over rest of left lung. Over whole right front respiration much diminished, slightly amphoric, especially below line of nipple, where the sounds are increased and metallic with pectoriloquy. Over left front no râles. In left axilla below sixth rib slightly bronchial with slight bronchophony. Same signs in left back below angle of scapula, with a few fine and medium moist râles after cough, and increased fremitus. The cardiac area extends one inch outside the mammary line, and upwards to upper border of third rib. Three days later a double drainage tube was inserted by Dr. Shattuck and fifteen ounces of thick, offensive pus removed. Cavity washed out with carbolic solution (one to eighty) morning and evening for following week. Patient now able to sit up half an hour at a time.

August 20th. Exchanging tube for a shorter one, a pus pocket was discovered. Diarrhœa still continues.

August 21st. Pus more fetid. Solution of corrosive sublimate 1 to 2000 substituted for carbolic wash. The diarrhœa ceased early in September, and the middle of the month he was moved to tent on the lawn. Sits up each day, though with some pain in right flank.

September 30th. Respiration now extends nearly to base of right back. Percussion still tympanitic.

December 1st. No change has been made by me in the treatment as directed by Dr. Shattuck. Removal from tent to ward in October induced some temporary discomfort only. The tubes have been gradually shortened, and to-day the washings omitted and tube removed. Small sinus through the parietes only. Walks nearly erect. Still slight tympany over right front and diminished respiration, especially below lower angle of scapula. Heart and liver gradually resuming normal position.

December 7th. Sinus healed, and patient ready to leave hospital at any time.

CASE II. McGuire, aged thirty-five, entered hospital with phthisis, October 13th. Has had cough for a year, and last spring a hæmorrhage of doubtful origin. Expectoration abundant and greenish. Two months since had paralysis of motion and sensation on left side lasting for six days, when the hemiplegia gradually disappeared. Complains now of dyspnœa, pain in loins, back, and in chest near ensiform cartilage. No night sweats.

In semi-prone position dullness is found below right clavicle with abundant moist râles, and to a less degree over whole right front. Percussion tympanitic over left front, especially between nipple and right edge of sternum; becomes flat at lower border of fifth rib. Metallic tinkling and absence of respiration over left front.

In erect posture dullness half an inch above angle of scapula, and above this line slightly tympanitic. Respiration faint. Right supra-spinous fossa dull, with moist râles extending over right back. Respiration harsh and exaggerated.

Tinkling and splashing in the left back.

The heart apex is in the fifth right interspace half an inch inside the nipple. The left border of the cardiac dullness is two inches to the right of the median line of the sternum. No murmurs.

The liver dullness extends two inches below the ribs.

CASE III. McCarthy, aged seventeen, entered the hospital November 15th. His mother died of phthisis. Had been taken sick ten weeks before with cough, dyspnœa, pain in side, chilly sensations, and loss of weight and strength. Neither hemoptysis nor night sweats. Chest had been tapped twice, seven and four weeks before entrance, getting about three pints each time, the first being clear, the second cloudy. Says that ten days ago while ascending stairs he was seized with a sudden sharp pain in left chest and aggravated dyspnœa. Present condition comfortable, good appetite, no pain. Temperature 98.2° F.; pulse 100; respiration 24.

In recumbent position there is tympany over the whole left front to the lower border of the seventh rib in the mammary line. Respiration and vocal fremitus diminished. Voice unduly clear. Respiration over right front harsh and exaggerated.

In erect position left front flat below. Splashing and metallic tinkling above.

Normal area of heart tympanitic. Apex sounds loudest just below ensiform. Right border one and seven eighths inches to right of sternum. Liver depressed one and one fourth inches.

December 1st. Tympany, in recumbent posture, over left front down to lower border fifth rib; in erect posture line of flatness rises to upper border of second rib with diminished respiration and absence of fremitus, with the heart a little farther to the right.

December 2d. Fifty ounces of slightly purulent fluid removed to-day to relieve dyspnœa.

December 7th. Liver still depressed, respiration on right side extends to the seventh rib. Splashing very evident on succussion.

Dr. F. C. Shattuck remarked on the great treat which Dr. Lyman had afforded the Society by the simultaneous exhibition of three cases of pneumo-hydro-thorax, illustrating so admirably as many modes of origin of the condition. As a complication of phthisis pneumo-hydro-thorax is not so rare; but special interest is attached to the man who was stabbed, and to the third case in which the lung seemed to be sound. Dr. Shattuck treated the case of a young man, a druggist's clerk, who was brought into the Massachusetts Hospital some years ago, and whose chest wall was perforated by one of those lance-head shaped knives, used for erasing writing, in the hands of a fellow clerk with whom the patient was "fooling." General pneumothorax resulted, but no fluid was thrown out, and the man made a rapid recovery.

Dr. G. B. Shattuck said that corrosive sublimate 1 to 2000 was used in washing out the thorax of the first case while in his care, and it had been more satisfactory than anything else he had ever used.

Dr. H. W. Williams read a paper on

APPARENT AND REAL AMAUROSIS.[1]

Dr. Wadsworth said the first case reminded him of a patient, a chronic invalid from asserted hip or spinal disease, who complained of photophobia so great that her room must be constantly darkened, and when she drove out the windows of the carriage were also darkened and her eyes bandaged. By proceeding carefully he was able to make an ophthalmoscopic examination, even of the macular region, without eliciting any sign of annoyance. It is often difficult to distinguish real from asserted loss of sight without ophthalmoscopic examination; even sometimes with it. If there is perception of light in neither eye the pupils should be dilated and without reaction; if one eye only is blind its pupil varies with that of the other eye, but dilates when the other is covered. Should blindness not be total, however, the value of this symptom is lost. He referred to the case of a young woman who had accidentally discovered that the sight of one eye was much impaired. Five weeks later, when she presented herself, the eye was wholly blind. Externally and on careful ophthalmoscopic examination both eyes appeared quite normal, with the exception that the pupil of the blind eye was dilated and immovable when the other eye was covered. There had been no other symptom, general or local. The case was somewhat of a puzzle, but the condition of the pupil and the absence of any symptom of hysteria allowed no doubt as to the truth of the blindness. For two or three weeks the condition was unchanged, then the patient was lost sight of for six months; and when she reappeared there was pronounced atrophy of the disk. The influence of reflex action in causing temporary loss of sight was illustrated by the case of a gentleman struck on the lower lid by a stick. An hour afterward the lid was ecchymosed and very sensitive, there was photophobia, the pupil was smaller than that of the other eye, but in other respects the eye was externally normal. Vision was only $\frac{6}{75}$. Homatropine and a night's rest restored sight.

The difficulty in detecting a malingerer who has studied the subject may be great. An applicant for a pension wore dark glasses, complained of sensitiveness to light, and asserted that one eye was almost completely blind, vision of the other very much impaired. He imitated the behavior of an amblyope very well. On examination with test types at different distances his answers were consistent. He bore ophthalmoscopic examination, however, without giving evidence of sensitiveness to light, and his fundus was normal in both eyes. On testing the blind eye by thrusting the finger suddenly at it while the other was covered he did not wink; but he went too far, for even when the finger touched the cornea he made no sign. Finally, with paralyzed accommodation he was given spectacles containing a strong convex glass before the blind eye, a concave glass before the other. With these he read slowly large print at six inches. The reading must have been done with the asserted blind eye.

Dr. Edes had seen one of the cases (No. III.) reported by Dr. Williams. The young lady was sent to him by another oculist who suspected some constitutional origin for the loss of vision. Dr. Edes said that the patient had some vision, and could for instance recognize the figure of a bird on a screen across the room. The pupils were widely dilated and were apparently but little sensitive to light. The ophthalmoscope showed nothing. In her history was mentioned swelling of the feet and ankles several weeks ago.

The urine was examined and found to contain a small amount of albumen and casts, composed partly of hyaline material with epithelium. Others of broken-down epithelium and some fragments of almost waxy appearance.

Loss of vision sometimes occurs in cases of Bright's disease unconnected with the well-known characteristic changes in the retina. Is it possible in this case that there is a causal relation between the albuminuria and the loss of vision, or is the coincidence accidental?

Dr. Williams referred to the extreme difficulty of detection of simulated amaurosis in both eyes, as the usual tests by which pretended blindness in one eye can be unmasked are here unavailing. Where only one eye is falsely asserted to be blind the claim is disproved by the use of a prism or a colored glass held before the seeing eye by which the patient is made to see two objects instead of one, which would be the case if he were blind of one eye. It is also instantly disproved if he is able to read when a pencil is held, vertically to the printed lines, a short distance from a book. He can only read if he has vision with both eyes.

Cases of feigned or hysterical photophobia are much more frequent than those of pretended amaurosis, the patients sometimes secluding themselves from all light for months and even for years, when there is no organic disease of the eyes, and where recovery within

[1] See page 577 of this number of the Journal.

a brief period is obtained by suitable tonic and moral treatment and encouragement.

DR. C. H. WILLIAMS spoke of the subcutaneous use of strychnia in the treatment of hysterical amaurosis. He had used it at the infirmary, but had not been able to satisfy himself of its value. The chance of the duration of this symptom being self limited, is such that it is hard to feel sure that relief is due to the drug used.

FIBROID AND OVARIAN TUMORS REMOVED BY ABDOMINAL SECTION.

DR. JOHN HOMANS showed five tumors from four patients, two of them fibroid and three ovarian. The first was a solid fibroid, weighing seven and a half pounds, from a girl twenty-one years old. Severe pain, hæmorrhage, the rapid growth of the tumor, and the age of the patient, with the knowledge that such cases had recovered in a certain number of instances, had decided him to operate. There was a good pedicle, which was clamped in Kœberle's serre-nœud, and held above the pubes by a transfixing pin. The tension, however, was great enough to bend the pin. The patient did well for a few days, then the clamp came off, and the pedicle retracted, leaving a cavity, with black walls, leading towards the pelvis. Her strength failed, and she died at the end of ten days, probably of septicæmia. The stomach was found at the autopsy to be enormously distended, and nearly filled the abdominal cavity; it contained much gas and six pounds of black fluid similar to that vomited during life. The nutritive enemata had all been absorbed.

In his opinion cases like this, with twenty years of menstrual life before them, are the cases for operation rather than immense tumors in exhausted women.

The second case was a fibroid from a woman of thirty-six, in whom the same reasoning had led him to operate, although neither the pain nor the hæmorrhage were so severe. The omentum proved to be adherent in the pubic region, and it was tied in two places and divided between the ligatures. The pedicle was the uterus, which was compressed in a clamp together with the left Fallopian tube and left ovary. He proceeded, as in ovariotomy, to tie, burn, and drop back the stump. Previous to operating there had been a trace of albumen in the urine, and it has since increased. The pulse has become very feeble and rapid, 140–160. To-night the temperature is rising somewhat, and the result is doubtful.[1]

The third case was ovarian, and consisted of two tumors, papillomatous, from a patient who is now getting well. There had been obscure pelvic trouble, with nothing to be seen externally, but one could feel masses in the pelvis, one of which at least appeared to be distinct from the uterus. Operation showed a papillomatous tumor of each ovary rather larger than the first. These tumors were of the variety more properly called multicystic than multilocular, a kind particularly hard to remove, as they do not pull out easily, and have very short pedicles. Papilloma in a cyst is almost like cancer. In fact, in the speaker's opinion all ovarian tumors, structurally, are much like cancer. He has removed them, and in one or two instances has seen the patient die of cancer afterward.

The fifth tumor was ovarian, connected with a fibroid uterus, and accompanied by much pain. The operation was attended by much hæmorrhage from adhesions in the neighborhood of the cæcum and right broad ligament.

One who does much abdominal surgery is reluctant to remove a fibroid tumor by laparotomy. His own experience has not been very encouraging, his mortality having been about twenty-five per cent. The speaker mentioned another case in which he had removed a fibroid tumor by laparotomy, clamping the uterus with Kœberle's serre-nœud. After the serre-nœud had come off the tumor began to be extended and to *grow* (!) until at last a mass four pounds in weight lay on the abdomen above the abdominal wound. This was removed by ligature and the scissors. The patient recovered.

[1] Since this report the symptoms have become more favorable, and, December 15th, the patient is convalescent.

ACID ROPY URINE.

DR. EDES showed a specimen of urine containing a large amount of mucin. It poured from one vessel to another like white of egg. It was not the well-known urine of cystitis, that is, containing pus altered by ammoniacal fermentation, but was acid in reaction, and gave the tests of mucin. The patient was hemiplegic and had no bladder symptoms.

NEW YORK ACADEMY OF MEDICINE.

NOMINATION OF OFFICERS.

AT a stated meeting of the Academy held December 4th, the nomination of officers took place, and among them were the following: For President, Drs. T. Gaillard Thomas, Wm. T. Lusk, A. Jacobi, C. R. Agnew, and S. T. Hubbard; for Vice-President, Drs. T. A. Emmet and C. C. Lee.

The paper of the evening was by DR. JOSEPH E. WINTERS, on

IS THE OPERATION OF TRACHEOTOMY IN DIPHTHERITIC CROUP DANGEROUS? WHEN SHOULD THE OPERATION BE PERFORMED?

Dr. Winters had invited a large number of medical students from the University to hear his paper, and as they came early and almost completely filled the hall, many Fellows of the Academy who arrived a little later were unable to obtain seats. He commenced by saying that he had prepared the paper because he felt it was not right that the sentiment that this was the most dangerous of all operations in surgery, which had been expressed by the author of a paper read before the Obstetric Section in March last (Dr. Ripley), should go forth as the dictum of the New York Academy of Medicine.

The operation not dangerous. He then criticised the opinions of Mr. Timothy Holmes and Prof. S. D. Gross in regard to the risk of the operation, and in speaking of the danger from hæmorrhage (which he thought had been greatly exaggerated) he expressed the opinion that the precaution advocated by Dr. Gross when the isthmus of the thyroid gland had to be divided, of first applying ligatures about the portion on either side, was a mistake as unnecessarily complicating the procedure. He next quoted from a large number of authorities, both ancient and modern, to show that the operation was not dangerous.

How does diphtheritic croup tend to produce death when left to itself? In a large proportion of cases, he said, by the prevention of access of air to the lungs,

and when the operation of tracheotomy failed to save life, it was either because it had been postponed until too late, or because the after-treatment had not been attended to with sufficient care. Tracheotomy accomplished perfectly its primary object of preventing death by asphyxia. In this connection he went on to show from various writers that diphtheria of the wound was rare, and that the disease seldom extended down the trachea after the operation. He had expected to find frequent reference to this matter among the German authorities, but this was not the case. As a rule, they believed that diphtheria of the wound could almost always be avoided by the use of carbolic washes, and that if the complication should occur it could easily be combated by the same means.

When to perform tracheotomy. Having referred to the folly of trusting to spontaneous expectoration of the membranes, such as had been known to occur in a very few exceptional instances, he gave some statistics of the course of the disease with and without operation, and said that the figures adduced were conclusive as to the necessity for surgical interference. Nothing was to be gained by delay in resorting to this, while, on the other hand, delay was extremely apt to seriously compromise the successful termination of the case. Then enumerating the symptoms present in the advanced stage of croup, he condemned in the strongest terms the practice advised by many of waiting till death was imminent before operating, and said that it was just as rational in strangulated hernia to wait until the occurrence of gangrene. Autopsies in cases of diphtheritic croup showed that where no operation had been performed or where it had been deferred until the third stage, death following soon after, the lungs and bronchi were in a state of marked venous congestion, and sometimes pneumonic consolidation, while no such condition was found in cases where tracheotomy was resorted to early. This condition was the effect, then, not of the operation, but of continued obstruction of the larynx. Pure warm air was the best remedy for diphtheritic croup, and in the majority of fatal cases of the disease death was due to want of oxygen and the exhaustion of the nervous system. The physician should not, therefore, wait until the results of protracted obstruction to respiration were evident, but, by operating early, restore to the patient the benefit of the life-giving properties of oxygen, nature's sovereign remedy.

Prognosis. Among the conditions unfavorable to the success of the operation were mentioned early age, previous ill health, the prevalence of scarlatina or measles in the neighborhood when the child had not already had them, and the presence of nasal diphtheria or enlarged lymphatics. No age, however, contra-indicated tracheotomy, as it had been successfully performed in infants of six and nine weeks. If after the operation the breathing did not become free or there was difficulty in swallowing it was to be regarded as a bad sign. Dr. Winters having again dwelt upon the dangers of delay, and mentioned a number of instances illustrating this, said that every practitioner of medicine should be ready to perform tracheotomy at any moment when the emergency for it might arise, and said that in communities where diphtheria prevailed its performance ought to be as common as venesection used to be in former times. He then gave a summary of the history of the operation, which he said had several times fallen completely into disuse, and announced a large number of *conclusions*, among which were the following: —

The operation of itself, performed with proper care, involved but little danger. Want of care in operating might result in serious accidents.

Tracheotomy prevented asphyxia, which was the most common cause of death.

It also prevented the extension of the original disease.

The operation should be performed early.

It was never too late to operate.

The operation never added one element of danger to the case.

Performed with care it would save two fifths of the patients.

No patient who died after the operation would have lived if it had not been performed.

The paper being open for discussion, DR. J. W. WRIGHT said that while the circumstances in which tracheotomy was most frequently called for in New York, namely, in young children living in tenement-houses, were undoubtedly very discouraging the difficulties attending such cases were not so great but that they might be overcome by the aid of coolness and careful attention. If the attempt was made to control all hæmorrhage before opening the trachea, as advised by some, it would usually be found a very formidable undertaking. If the symptoms were not especially urgent it was well to stop the hæmorrhage to some extent, but if they were he thought it was best to ignore venous hæmorrhage altogether, and to go right on into the trachea as quickly as possible. As the writer of the paper had stated, the flow of blood would cease as soon as the knife entered the latter, or, at all events, as soon as the tube was inserted. With regard to blood getting into the trachea, he could see no special objection to this. Indeed, it had sometimes seemed to him to be of decided advantage, since it was just what was needed to excite violent expulsive efforts which would clear the trachea not only of blood, but of the mucus which was stopping it up. In young children the operation, he thought, was always facilitated by placing an ordinary wine bottle, wrapped in a towel, underneath the back of the neck. When the isthmus of the thyroid gland was in the way he believed that it should be cut through at once without any attempt to control the hæmorrhage whatever in cases of urgency, but where there was no necessity for such haste he thought it was advisable to put ligatures around the two portions and divide the isthmus between them in the manner referred to in the paper. To be of very much use, he agreed with Dr. Winters, tracheotomy ought to be resorted to early. In any case where there was a certain diagnosis of diphtheritic croup, with serious symptoms in connection with respiration which medicinal measures failed to relieve, it was the physician's duty to perform it. The operation was not in any sense a cause of death.

DR. A. JACOBI said that in the paper but one danger had been referred to, namely, hæmorrhage, and that while a vast number of European authors had been quoted in support of the writer's position that tracheotomy was not dangerous, about the only American mentioned had been Professor Gross, who, indeed, was cited merely for the purpose of showing certain apparent inconsistencies in his works. There were many others in this country who had made valuable contributions to this subject who might also have been quoted

with advantage, and among these he mentioned particularly Dr. Gay, of Boston, and Drs. Hadden and Ripley, of New York. As to the dangers of tracheotomy, the principal one was bungling operations. If properly performed it was not usually a bloody operation; but hæmorrhage occurred very frequently when it was done by a careless operator or one who was in haste to get through with it. The main point of success was to operate with deliberation. The trachea should not be cut into until it could be plainly seen, and if the isthmus was encountered, in getting access to it, it was advisable to peel a part of it off, according to the practice of Dr. Voss. It was certainly a great mistake, as a rule, to cut through the isthmus, and this procedure was only justifiable when the case was extremely urgent. When there was much hæmorrhage it was often very difficult to find the trachea at all, and he could not agree with Dr. Wright that it was a matter of indifference whether blood got into the latter or not. All of it would not be coughed off, and some of it would be almost certain to go down into the smaller bronchi and air-cells, and perhaps give rise to broncho-pneumonia, which, from this cause, was very frequent after tracheotomy. Another danger arose from operating without anæsthetics, on account of the violent struggles of the child, and chloroform was preferable to ether, because the inhalation of the latter required a longer time, and also excited more struggling. He did not agree with Drs. Winters and Wright that it was necessary to have a positive diagnosis of diphtheritic croup before operating. The principle on which he acted was, whenever there was serious laryngeal stenosis, whether membranes were present or not, to perform tracheotomy. There were some cases of simple laryngitis in which the obstruction was sufficient to cause death by asphyxia. Pneumonia was not a contra-indication, and in cases in which there was sepsis from diphtheria, there was all the more necessity for operating, since by the opening of the trachea the fetid inhalations from the mouth and nose were cut off. In ordinary cases of membranous croup, however, it was usually safe to defer tracheotomy until a fair trial of bichloride of mercury, in addition to other remedies, had been tried. As to the efficacy of this drug, he still entertained the same favorable opinion that he had expressed in his paper before the Obstetric Section of the Academy in May last, and he was happy to say that his percentage of recoveries without tracheotomy had of late been much larger than ever before.

As to the cause of death after operation, many died of diphtheria and many of croup. Among the special causes were the following: (1.) Diphtheritic sepsis. (2.) Complications of diphtheria, such as paralysis, nephritis, adenitis, fibrinous pneumonia, etc. (3.) Broncho-pneumonia or œdema of the lungs (the most frequent of all); and (4.) The descending diphtheritic process. Many cases appeared to do well for twenty-four hours after the operation, when there would be a change for the worse, and death would ensue in about sixty hours from suffocation consequent upon the extension of the membranes down to the ramifications of the bronchi.

DR. J. LEWIS SMITH, having mentioned that all authorities were agreed that the older the child was, other things being equal, the better the chance of success, said that these two combinations of circumstances rendered tracheotomy especially dangerous, namely, when in consequence of the patient's being nearly moribund the physician was induced to operate hastily and without paying sufficient attention to the control of hæmorrhage, and, secondly, when proper precautionary measures were neglected by a novice. He fully agreed with Dr. Jacobi that the degree of stenosis should be the guide for operation, whatever the diagnosis might be, and referred to two cases of acute catarrhal laryngitis, without pseudo-membrane, which had proved fatal at the New York Foundling Asylum. The cases of diphtheritic croup could be divided into two classes. In the first, the inflammation of the larynx commenced at a very early period, with rapid extension of the exudation, and the early performance of tracheotomy was called for. In the second the larynx was attacked later, and the pseudo-membrane did not spread so rapidly; so that there was more time for the trial of other remedial measures before resorting to the operation. In the first rank of these he placed alkaline inhalations, and he said that in cases of diphtheria he had again and again prevented the serious invasion of the larynx by the pseudo-membrane by promptly resorting to these the instant that it was discovered that laryngeal trouble was threatened. In this connection he spoke of the great importance of watching very closely the voice of the patient from day to day in every case of diphtheria. Finally, he referred to catheterization of the larynx as having been employed with some success at the Foundling Hospital as a substitute for tracheotomy in cases where the membrane did not extend very far down.

DR. JOHN H. RIPLEY remarked that the position which had been taken by the author of the paper was in direct opposition in almost every particular to that which he himself occupied. At the meeting of the Obstetric Section of the Academy to which Dr. Winters had referred he did not say that tracheotomy was the most dangerous of all surgical operations, but that tracheotomy for croup in young children was one of the most dangerous operations in surgery. The question was not whether tracheotomy in general was difficult and dangerous, but whether in young children suffering from croup it was difficult and dangerous. Under such circumstances he believed that it was, and the danger consisted principally in the critical condition of the patient and the necessity for performing the operation within a certain time. Dr. Winters had alluded to but one possible source of danger, namely, hæmorrhage, but he did not consider that this was the most common cause of death. The child operated on, it must be remembered, was suffering from a diseased system, a stenosed larynx, and often an infiltrated neck. Sometimes it was so paralyzed with the poison of diphtheria that it was liable to die at any moment from syncope, and if the stenosis was very great it might die of apnœa, while in order to get at the trachea it was, perhaps, necessary to go down for two inches, which involved both time and great care. He was content to go with the small minority, which included such names as those of Gross and Holmes and Billroth, in the opinion that the operation was a dangerous one, and he believed that this was shared by a large number of New York surgeons. He had himself peformed tracheotomy at least one hundred and ten times, and he had also seen it done by others at least fifty times. He had met with almost every complication that could exist, and had seen all kinds of men take a trial at the operation. He believed that he had been the means of saving some lives where it was attempted by inexpe-

rienced operators, but he had also seen a number of cases die on the table. Some of these had been in the hands of men of marked surgical ability, and he had once witnessed the puncture of the internal jugular vein by one of the best surgeons that the city of New York ever had. It had been stated that it was a simple matter to plunge a knife into the trachea, but he had seen two or three such attempted plunges which were rather disastrous in their effects. One of them was into the spinal column, another into the œsophagus, and another entered the side of the trachea and passed through it. The comparatively greater success of those who operated early was due, not to the relief afforded by the tracheotomy, but because early operations were, as a rule, unnecessary ones. Many of the cases of croup recovered without operation, and, in fact, with very little treatment of any kind, and it was also often difficult to make a positive diagnosis between true croup and catarrhal laryngitis, which almost invariably recovered without operation. These facts accounted for the number of specifics for croup of which we heard so much. He did not agree with Dr. Winters that the obstruction to respiration produced pulmonary congestion, often with the final result of pneumonia. On the contrary, his experience with the disease during life and the autopsies which he had seen led him to believe that there was anæmia of the lungs with hyper-dilatation of the air vesicles (resulting from the attempt to fill up the threatened vacuum), and occasional areas of collapsed lung tissue. The most common cause of death after tracheotomy was bronchial croup from extension of the pseudo-membrane, which would produce a fatal result by suffocation long before the air vesicles were reached by the membrane. Other prominent causes were nephritis with uræmic poisoning, and respiratory and cardiac paralysis. When it was possible he believed that an inexperienced man should always call in an experienced one to assist him in operating.

DR. WINTERS made some extended remarks in reply to the criticisms of the various speakers on his paper. In the course of them he said that he had not by any means attempted to make the latter a complete treatise on the subject, though he had quoted from several other American authors beside Dr. Gross. Among these were Dr. Pooley, professor of surgery in Starling Medical College, and Dr. Mastin, of Mobile, Alabama. Properly performed the operation was almost bloodless, and he advised that the scalpel should be laid aside altogether as soon as the incision through the skin was made, and that a careful dissection of the tissues should follow until the trachea was reached. Dr. Ripley, it seemed to him, had confounded the dangers of the operation with those of the disease, and he still claimed that the operation itself, performed with care, was not dangerous. When death took place on the table he believed it was always due either to carelessness on the part of the operator or to a too late performance of the operation.

— For a number of years it has been the custom in Dublin to have an annual foot-ball game the day before Hospital Sunday for the benefit of the Hospital Sunday fund. This year the game netted some £54 to the good cause. In this country the advantages accruing to hospitals from foot-ball games are chiefly clinical.

REGULAR MEETING OF THE CHICAGO GYNÆCOLOGICAL SOCIETY.

W. W. JAGGARD, M. D., SECRETARY.

No. 536 WASHINGTON BOULEVARD. FRIDAY, NOVEMBER 21, 1884. The President, H. P. MERRIMAN, M. D., in the chair.

DR. EDWARD WARREN SAWYER opened the discussion on the

TREATMENT OF ABORTION.

He called attention to the frequency of the interruption of pregnancy before fœtal viability. Madame La Chapelle says abortions are as frequent as labors at full term. The experience of the profession oppose the generalization. In his own practice, extending through a period of ten years, he had only seen from forty to forty-five abortions. As illustrative of the wonderful conservatism and care of nature in these cases, he had never met with a fatal case in his own practice, and had seen but one fatal case in the practices of his medical brothers. This fatal case was complicated by cellulitis and pneumonia.

As to causation, abortions are divisible into two classes: (1) those occasioned by natural processes; (2) those induced by accidental or intentional violence. The former class usually terminates favorably. The latter class is the *bête noir* of the physician. It is a matter of medico-legal interest, that in abortions, resulting from natural processes, that is, fatty degeneration of the decidua, the ovum and decidua are expelled, as a rule, in an intact condition, while in criminal abortion the product of conception is expelled in a more or less mutilated state. When the ovum has been mutilated, the embryo is extruded from the cavity of the uterus before the fœtal envelopes and decidua, and is frequently lost. Moreover, the embryo, so late as the fourth week, may be completely absorbed. The absence of the fœtus cannot be regarded in the differential diagnosis of abortion, molar pregnancy, or intra-uterine fibroids. Two distinct courses, as to the treatment of abortion, have been adopted by the profession. The radical method of immediate evacuation of the contents of the uterine cavity and the plan of patient waiting have been, in turn, defended and opposed. Dr. Sawyer has followed the expectant mode of treatment. He waits and allows nature to effect the expulsion of the product of conception. He has waited as long as one week. He has been encouraged in this line of treatment by the fact that he has never seen any untoward consequence in the cases managed in this manner. He enjoins absolute rest in the horizontal position, and the exhibition of quinine and alcohol, as required. Local treatment, apart from the vaginal tampon, is limited to vaginal injections of chlorinated soda. He has never noticed hæmorrhage or inflammatory action as the result of this course of action. He objects to the removal of the whole or part of the product of conception from the uterine cavity because (1) it is a painful procedure involving the use of ether, and predisposing to hæmorrhage from uterine inertia; (2) an assistant is necessary; (3) the amount of unavoidable injury to the genital tract is considerable.

In conclusion Dr. Sawyer exhibited an unusual specimen. The specimen consisted of an intact amniotic sac, inclosing a five months' fœtus, with velamentous insertion of the umbilical cord. Separation had

occurred between amnion and chorion. The chorion, placenta, and decidua remaining within the cavity of the uterus. He had been called to see the woman, — five months advanced in pregnancy, — who was suffering from severe uterine contractions and hæmorrhage. After a brief interval, the specimen presented to the Society was expelled. Noting the intact condition of the amnion, Dr. Sawyer paid no further attention to the mass, told the woman to fear no more trouble, and went home. Next morning, upon visiting his patient, he was informed that one hour after his departure, under renewed hæmorrhage and uterine contractions, another mass was expelled. This second mass proved to be the chorion, placenta, and decidua. A medical friend, Dr. Albert G. Paine, had observed a strictly similar case.

DR. W. W. JAGGARD said separation between the amnion and chorion was relatively infrequent during the sixth and seventh months, but was not uncommon prior to that period. In regard to the treatment of inevitable abortion when the ovum was expelled in an intact or mutilated condition, and decidua or portions of the fœtal membranes remained within the uterine cavity, it was necessary to regard the natural history of the condition. This condition had been appropriately termed by Breslau "incomplete abortion." The terminations are briefly: —

(*a.*) Spontaneous elimination of that portion of the product of conception remaining within the uterine cavity, as the result of retrograde metamorphoses, accompanied by intermittent hæmorrhages and uterine contractions.

(*b.*) Sometimes — though seldom — hæmorrhage ceases entirely, and the patient is apparently well. This interval varies from a few days or weeks to months. Suddenly hæmorrhage and pain occur, and the intra-uterine mass is expelled. This retention, with a long interval of rest, is noticed when the placental or decidual attachments are intact. That this act constitutes the termination of the labor, so to speak, is apparent from the facts that the milk secretion is usually established at this time, and the reductive metamorphosis is instituted.

(*c.*) More frequently the retained decidua or placenta undergoes suppurative or ichorous changes, as the result of which systemic infection was liable to occur despite the thrombosis of the uterine sinuses, and the proliferative changes in the uterine mucosa.

(*d.*) The retained placenta or decidua may become converted into placental or fibrinous polyps, conditions which always require operative interference.

All four terminations present sources of danger to the mother. From this glance at the natural history of the condition — for the elucidation of which Spiegelberg deserves especial recognition — the weight of evidence lies in favor of the so-called radical treatment, — empty the cavity of the uterus at the earliest possible period. The plan recommended by Dr. Mundé in the February number of the *American Journal of Obstetrics*, 1883, was worthy of high commendation. One finger within the uterus, one hand on the fundus, was preferable to instruments when equally effective. The subsequent treatment was one of extreme importance.

Whenever the cavity of the uterus is invaded by the finger or any instrument it must be irrigated by some antiseptic solution. Two per cent. solutions of carbolic acid or one to two thousand of the bichloride of mercury are efficient in the destruction of conditions favoring decomposition and sepsis. After irrigation of the cavity of the uterus it was a good plan to introduce within the uterus a *bacillus* of powdered iodoform weighing at least six grammes. Symptoms of iodoform intoxication rarely, if ever, followed the exhibition of this quantity. Ten grammes are usually required to produce toxæmia.

DR. PHILIP ADOLPHUS said that abortions were more frequent among multipara than primipara. In the way of prophylactic treatment, he thought women ought to sleep by themselves during the time corresponding to their menstrual periods. Among the upper classes in Europe it is customary for man and wife to sleep in separate beds. He thought it an excellent plan. When abortion was inevitable, the treatment must be symptomatic. To arrest hæmorrhage plug the cervix, not the vagina. Use tupelo or laminaria tents, not those composed of sponge, for various reasons. Use thin tents. When fetor is noticed, empty the uterine cavity. For this purpose either finger or curette might be employed.

DR. D. T. NELSON said the dangers from abortion were (1) hæmorrhage, (2) sepsis, (3) inflammation. Rest and opium were not sufficient. He could not rest until the uterine cavity was empty. He had no sympathy with the expectant plan of treatment. The manner of emptying the uterine cavity was of importance. If the cervix was dilated, or dilatable, the cavity should at once be cleaned out with the finger. If the cervix was not dilated, nor dilatable, the cervix ought to be plugged in the manner indicated by Dr. Adolphus, with tupelo or laminaria tents. If the cervix was partially dilated or dilatable, and the uterus fixed, give an anæsthetic, relax the spasm, and proceed as in the first case. He had no fear of ether predisposing to uterine inertia. In dissecting off the placenta it was advisable to glove the finger tips with the amnion. In the early months, when the ovum was attached near the cornua, it was necessary to bear in mind the possibility of irregular contraction, and the inclusion within either cornu of a bit of the placenta. The cornua must be thoroughly explored. When he employed intra-uterine irrigation — by no means an invariable method of treatment — he used a one half per cent. solution of carbolic acid, or a dilute solution of ordinary table salt. The solution must be hot, 110° F. to 120° F. Hot water, in the absence of carbolic acid or salt, was effective as a cleansing agent, and as inducing uterine contractions. Dr. Nelson had had no experience whatsoever with iodoform, but regarded it as superfluous in all cases.

DR. WM. E. CLARKE was more afraid of hæmorrhage and sepsis than of inflicting injury upon the genital tract. He always emptied the uterine cavity at the earliest possible period.

DR. T. D. FITCH did not consider Dr. Sawyer's specimen a rare pathological occurrence. He had seen the same separate at the same time frequently. He agreed with Dr. Nelson in treatment. Still when the cervix was not dilated he was disposed to pursue the expectant line of treatment. At the time of the occurrence of abortion the uterus was in a physiological condition. Operative interference at a later period was attended by increased risk, as the uterus was then in a pathological state. Usually he found the placenta and membranes detached within the lower segment of the uterus. As he had a large hand with short fingers

he employed the placental forceps of Hodge, Dewees, Elliott, or Koler. Once, in the country, he used an ordinary pail bail with the rough edges filed off. He was not in favor of intra-uterine injections. The vaginal douche was sufficient.

DR. WM. H. BYFORD said that abortions were more frequent in large cities than in the country. Madame La Chapelle's estimate of the frequency of abortion was not exaggerated when applied to large communities. In the country, he thought, one abortion to three labors at term represented a fair average. Abortion was never a physiological process, although abortions from diseases of the ovum were attended with less danger than those resulting from morbid uterine changes. In disease of the ovum the circulation was impaired, the embryo perished, and expulsion followed with the inimical degree of hæmorrhage, pain, and sepsis. When the cause of abortion was external violence or decidual endometritis danger in each of these three directions was increased. The specimen exhibited by Dr. Sawyer was of rare occurrence at so late a period; it was comparatively common during the early months.

As regards the prophylactic treatment he had observed two clinical facts in connection with the habit of abortion. When uterine contractions were the prominent symptom, abortion could be arrested in many cases by absolute rest and opium. When hæmorrhage was severe all attempts at arresting the process were usually futile. This was especially true during the first three months. At a later period, even when hæmorrhage was severe, abortion might be arrested.

In regard to the treatment of inevitable abortion, he had never seen the time when champions of the expectant and radical courses of action did not exist. The treatment must be governed by the consideration of the individual case. In any case the patient must be carefully watched. He had never seen a case of abortion terminating by immediately fatal hæmorrhage. The acute anæmias, however, might induce a condition which would render the woman more susceptible to sepsis or any intercurrent disease. He feared sepsis and metro-peritonitis more than hæmorrhage. He was conservative as to operative interference. Let Nature do what she can; only in case of failure on her part, interfere. The finger was preferable to any instrument. Then it was not necessary to insist upon the removal of placenta or membranes with mathematical accuracy. If the placenta was grasped by an irregularly contracted uterus, cut off the free portion, allow the rest to lie in the uterine cavity. If two thirds of the placenta were removed, and the uterus well contracted, the case was to be considered in a safe condition. In event of sepsis, remove all the intra-uterine mass.

DR. JOHN BARTLETT stated that, in his practice, abortions were as frequent as labors at term. The product of conception was usually expelled in its integrity. When abortion was inevitable, two conditions were required, before operative interference was justifiable: (1.) Dilatation of the canal of the cervix to the extent necessary for the passage of two fingers. (2.) The separation between decidua and the uterine mucosa must be more or less complete. Until these conditions were present, the vagina ought to be tamponed. For a tampon, he was in the habit of employing bits of cotton tied on a string in the manner of the kite-tail.

He had seen two cases in which the placenta had remained for a long period of time within the uterine cavity without causing symptoms. The retention in one case lasted through a period of three months; in the other case the period was four months. As to the length of time the tampon could be left *in situ* he had adopted Dr. De Laskie Miller's rule of allowing it to remain twenty-four hours. He had frequently tamponed through three days. The colpeurynter of Braun was a useful tampon. No tampon was effective when the hæmorrhage was not of a passive character, and uterine contractions were severe.

It was necessary to diagnosticate between placenta prævia and abortion. Placenta prævia implied simply an *error loci* of the ovum. It was included between the ring of Bandl and the external os. Dr. Bartlett had never seen a case of abortion terminate fatally from hæmorrhage.

DR. A. H. FOSTER had seen one case of retained placenta, in which the retained mass gave origin to no serious symptoms for a period of four months. The importance of subsequent treatment of the puerperium was urged.

DR. E. C. DUDLEY referred to the dangers of cervical laceration and subinvolution in consequence of abortion. The best method of applying the tampon was by means of Sims's speculum.

DR. C. W. EARLE occupied the middle ground between the expectant and the radical methods of treatment. He did not agree with Dr. Mundé.

DR. H. P. MERRIMAN, after indorsing Dr. Byford's remarks on the ætiology of the condition, said that he did not like to use ergot in these cases, as it caused irregular contractions of the internal os, imprisoning the placenta without favoring its expulsion. He produced uterine contractions by dilating the os, and then followed the expectant plan of treatment.

DR. E. W. SAWYER, in closing the discussion, said that he had observed abortion in the lower animals, and concluded nature required little interference. He then briefly sketched the line of expectant treatment, which he was in the habit of recommending.

CASTS OF THE PREGNANT AND NON-PREGNANT UTERUS.

DR. JOHN BARTLETT then exhibited some casts of the pregnant and non-pregnant uterus for the purpose of class illustration. The idea is an extremely ingenious one, and will receive attention at an early period.

The Society adjourned to meet December 19th at the residence of the President, Dr. H. P. Merriman, No. 1350 Michigan Avenue. Subject for next discussion, Extra-Uterine Pregnancy, to be introduced by Dr. William H. Byford by a paper On a Case of Interstitial Pregnancy.

—"Hot-eye" is the name given Mr. Jonathan Hutchinson in the "Bowman Lecture" for the current year to an affection occurring as a symptom in incomplete or "quiet" gout. One eye is usually affected, sometimes both. The conjunctiva is red and congested. The eye-ball pricks and feels hot, or as if sand were in it. The attack comes on soon after an error of diet, and lasts from a few hours to a day or two. It not infrequently is the precursor of iritis.

Medical and Surgical Journal.

THURSDAY, DECEMBER 18, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly by HOUGHTON, MIFFLIN AND COMPANY, *Boston. Price, 15 cents a number; $5.00 a year, including postage.*

All communications for the Editors, and all books for review, should be addressed to the Editors of the Boston Medical and Surgical Journal.

Subscriptions received, and single copies always for sale, by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter. HOUGHTON, MIFFLIN AND COMPANY,
No. 4 PARK STREET, BOSTON, MASS.

N. B. After January 1, 1885, the Journal will be published by CUPPLES, UPHAM & CO., *283 Washington Street, Boston.*

A PROPOSAL FOR A NEW NATIONAL HEALTH ORGANIZATION.

THE meeting of the Conference of State Boards of Health with the addition of the health authorities of a number of the more important cities of the Union, as well as of the Dominion of Canada, which was in session at Washington during the 10th and 11th of December, appears to have accomplished some important work, a special report of which, already in hand, we are obliged to postpone to next week. Three committees considered respectively questions of national, State, and municipal health organization; reports were made — though not yet made public — which will at least represent the views of those who are at present charged with official sanitary work.

The principal subject under consideration by the Committee on Federal Legislation — a reorganization of the National Board of Health — will probably attract general notice, both from the importance of the subject and from the fact that this body, substantially the same as the American Public Health Association, the founder and devoted adherent of the present National Board, has at last become reluctantly convinced that the present Board has lost its capacity for usefulness, without any abatement of respect or sincere good will on the part of the medical profession for its members individually.

The Convention represented twenty-seven States, and the Committee on Federal Legislation six States: Dr. Walcott, of Massachusetts, Chairman; Hon. Erastus Brooks, of New York, Drs. Smith, of New York, McCormack, of Kentucky, Rauch, of Illinois, Baker, of Michigan, and Herrick, of Louisiana.

Toward the close of the meeting of the Conference a project for a bill amending the Act of 1879 establishing the present Board was reported by the committee, this was recommitted to an enlarged committee with instructions to present a draft of an act of the same general tenor, and to submit the same to Congress. The Committee, with the addition of Drs. Chancellor, of Maryland, Elder, of Indiana, Hearne, of Mississippi, Thornton, of Tennessee, Horlbeck, of South Carolina, completed their bill and presented it to the Committee on Public Health of the House on Friday.

This bill, which is understood to have received the important assistance of a revision by the Secretary of State, is substantially the following: —

First. A Board composed of members representing State Boards of Health, appointed by the President, and confirmed by the Senate; to serve without pay except when actually employed, and then to receive a per diem allowance of $10 and necessary expenses; to meet in Washington once a year; to be convened at other times, if required, at the call of the Chairman or of the President; the officers to be a chairman and secretary, the latter to be the executive officer of and *ex officio* a member of the Board, and the only officer to receive a salary; the Board to have authority to assign any of its duties to the executive committee of seven, including the Chairman, and representing various sections of the country.

Second. The duties of the Board to be general and special, embracing investigations into epidemic and contagious diseases and causes of disease, and measures of aid in coöperation with State and local boards when necessary to protect the public health.

Third. The making of rules and regulations to control the sanitary condition of ships sailing from foreign ports to the United States.

Fourth. Framing rules and regulations for the quarantine service of the United States, and assisting in the enforcement of local regulations when needed.

Fifth. Authority to be conferred upon the President to issue proclamation of measures to be taken in cases of great emergency to be in force only until the Board or its Executive Committee can be convened. This section was added at the instance of the Secretary of State.

It is made the duty of the State Department to obtain information from consuls, or medical officers serving in offices of consuls, in regard to the sanitary condition of foreign ports, and the President is authorized, upon request of the Board, to appoint competent medical officers to serve abroad.

The bill further provides that officers may be detailed by the President from any regular service to assist the Board; that a bulletin shall be published giving all important information, and establishing a permanent office in Washington.

Upon careful examination the bill seems to have been framed with an evident intention to burden the Board with the least possible patronage, to impose upon existing departments as large a share of the executive work as could be done without injury, and to meddle as little as practicable with the ever-jealous Services at the capital. It has been intimated that this draft will not encounter the hostility of the Marine Hospital Service, inasmuch as provision is made by which the President may direct, as it seems proper that he should, what department or persons shall carry into effect the rules made by the Board.

The proposed legislation seems to us conservative and wise. If enacted it completes, in the same manner as does the National Government, the successive steps in the progress from the health organization of the smallest village in a State to the sanitary oversight of all the States and Territories of the Union. While the number of members may appear to some to be large, there seems no other way for securing a

truly representative body. As there is little probability, with a competent executive committee, of more than one annual meeting of the full Board, the general government will not be called upon to bear a serious burden of expense.

The urgency of some more direct representation of the sanitary needs of the country was shown by the action of the Secretary of the Treasury, who requested a conference with the Committee on Federal Legislation, and submitted to them his own draft of an amended Treasury order in relation to the vexed question of the importation of rags, with the assurance that the Committee's action would determine the course of the Department. The order upon this subject published in the daily press Saturday contains the recommendations of the Committee, whose influence is shown by the concluding provision allowing disinfection at foreign ports under proper supervision, a concession hitherto opposed by Mr. McCulloch.

Such a Board as that suggested by the Conference would go far to relieve the country of the reproach of a national organization which has so far lost public confidence as to fail of an appropriation sufficient for mere existence even, and which has not been strong enough to oppose the one-man power sheltered behind the Treasury.

THE ANNUAL REPORT OF THE SURGEON-GENERAL.

AMONG the great number of annual reports of the different government officials, that of the Surgeon-General of the Army is by no means the least interesting. Though dealing in great measure with statistical tables, whose chief value can only be reached by comparison with similar tables for former years, it still contains many items well worth attention.

The first subject noted concerns the distribution of trusses, in which the legal regulations cause apparent hardship, if not injustice; for instance, a soldier ruptured during the war with Mexico, although he may be receiving a pension on account of hernia, is not entitled to receive a truss. Under the law, as it now stands, the following classes of persons are not entitled to trusses: Those who were ruptured at any time while serving as commissioned officers; those who were ruptured prior to April 19, 1861, whether commissioned or enlisted, although the disability may have been incurred in the line of duty and during the prevalence of war; and those who have been ruptured since August 20, 1866, whether commissioned or enlisted, unless the disability may have been incurred in the line of duty during war.

It is recommended that existing law on this subject be so amended as to allow a truss to every person who has been, or may hereafter be, ruptured in the line of duty while serving in the army or navy.

In the report on the health of the army it has always been the custom to institute a comparison between the white and colored troops. This year, for the first time since their organization, the death-rate for the colored troops has fallen lower than that for white troops. The death-rate among the colored troops from respiratory diseases is more than four times as great as that of the white troops: the deaths being wholly from pneumonia. The colored troops present a higher rate than white troops for syphilitic and other venereal diseases. On the other hand, their comparative freedom from intemperance continues to be of interest.

No casualties whatever from actual warfare are reported, the year having been the first for many years not marked by losses to United States troops from Indian hostilities. Life in the army has not been without its perils, however. Increased interest in rifle practice has been followed by a number of accidents; the returns of the War Office showing for the year nine cases of shot wounds received at the firing range, with three deaths, and in addition forty-seven injuries from explosions of rifle-cartridges occurred while soldiers were preparing ammunition to be used in target practice.

Typhoid fever has been quite prevalent among the white troops, amounting to .6 per cent. of all cases of disease and injuries returned, or eleven per thousand of mean strength, while the average annual occurrence for the past sixteen years has been but 3.58 cases per thousand. Sixty-five per cent. of all the cases have occurred in the cavalry, though this arm of the service numbered less than thirty-four per cent. of the combatant force. Most of these cases occurred in young recruits, and the evidence shows that the Recruiting Depot at Jefferson Barracks, near St. Louis, Mo., was the source of a very wide-spread dissemination of typhoid and typho-malarial fevers.

The literary and scientific work of the Surgeon-General's Office is, probably, the most interesting portion of the army work to our readers. The Index Catalogue receives the barest mention, but we are glad to repeat the information that the manuscript of Volume VI. is in an advanced state of preparation, and the first part of it is now going to press.

The Library has become a matter of national pride, and its growth is watched with interest by the profession in all parts of the country. The increase in the appropriation has made it possible to arrange to have every new medical work from every country sent promptly to the Library, as recommended in the last Annual Report, and henceforward it is hoped that those who consult this collection will find that it contains the latest information on any subject in which they may be interested. The number of those using the Library is, very naturally, steadily increasing.

The long illness and death of the lamented Surgeon Woodward has delayed the publication of the Third Medical Volume, the last of the series of the Medical and Surgical History of the War. The completion of this volume has been intrusted to Surgeon Charles Smart, and its publication may be expected in about a year.

It is a lamentable fact that each year it is necessary to repeat the statement that a fire-proof building is a necessity for the proper protection of the Museum and Library. A bill for such a building, reported favorably to the House of Representatives, was not reached

in the order of business at the last session, and is still pending. A similar bill has already passed the Senate. We cannot feel that the legislators of the country who have already done so much to preserve the medical results of the fearful conflict between the States, and have so nobly encouraged the work of the Army Medical Department, will willingly longer imperil the safety of these valuable collections.

DISPOSAL OF SEWAGE AT PROVIDENCE. A SEWAGE BESIEGED CITY.

THE practice of casting sewage into the nearest water-course has finally brought the city of Providence, as it so lately brought Boston, and will sooner or later bring others of our large or growing cities, to a realizing sense of its sins in this particular. Whether the inhabitants are sufficiently conscious of the necessities of the situation to pay the inevitable price of reform, now estimated at $3,500,000 in round numbers, remains to be seen.

The city authorities, two years ago, directed the city engineer to report plans of intercepting sewers, and of any other work necessary for collecting, conducting, and disposing of the sewage of the city in accordance with best approved methods at such a point and in such a manner as would be least injurious to the public health. A year later the engineer, Mr. S. M. Gray, and his assistant were directed to proceed to Europe to investigate the various plans in practical operation for the disposition and utilization of sewage.

As a result we have before us a very handsome and complete report lately issued. The bulk of the report contained in Appendix A is taken up with a good account of the most important sewerage systems and methods of sewage disposal. It contains much the same information which was available in Boston before its new system of intercepting sewers was undertaken, and which was published in a Supplement of the National Board of Health Bulletins, prepared by Mr. Rudolf Hering. The results at Boston, are however, not referred to, probably as being too near home.

The present sewer-connections at Providence are believed to take the sewage from about 36,500 inhabitants; the daily dry weather flow of sewage of the town is estimated at about 3,000,000 gallons. In addition about 4,823,000 gallons of filthy liquid wastes of manufactories are emptied daily, except Sundays, into the small tributaries of the Providence River, at or near the town. A population of 300,000 is provided for in the estimate of the proposed system of intercepting sewers. It is recommended that the sewage be carried to comparatively deep water at Field's Point, where Providence River debouches into Narragansett Bay; that it be treated there by chemicals in such a manner as to precipitate the matters in suspension and clarify the sewage; and that the clarified effluent be then emptied into the Bay. The plan now pursued at Boston, of emptying the sewage without treating it, is impracticable on account of the feebler tide and smaller volume of water. The plan of utilizing the sewage for irrigation was duly considered, but the engineer says he did not feel justified in recommending its adoption, for, from careful and extended surveys, he became convinced that the large amount of suitable land required for the purpose could not be obtained at any reasonable cost within reasonable distance of the city. The amount of land required for the disposal of sewage by irrigation being placed at about one acre to 100 inhabitants, some 3000 acres would be necessary.

Mr. Gray states the cost of chemicals and labor for treating sewage by precipitation at well-managed works in England at from .24 cents to .36 cents per annum per inhabitant connected with the sewers, and thinks it might cost twice as much in this country, but apparently is not very positive or exact as to this point.

On such a basis it is calculated that purification can be accomplished by precipitation at far less expense than by irrigation, even though the residual sludge should possess no commercial value, but that it would possess some value as a fertilizer he has no doubt.

The taxpayers of Providence, whatever may be true of the voters, will probably find it hard to bring themselves to pay the price for relief from their present troubles, but delay will steadily augment both.

MEDICAL NOTES.

— An important and for this State novel experiment in the disposal of criminals has just been inaugurated at Concord, Mass., in the buildings recently vacated by the removal of the State Prison to Charlestown. A reformatory is to be established at the former place for the more corrigible of the criminal class. The determination of what cases shall be committed here has been left wholly with the courts, proposals for a limitation by law to first offenders and to prisoners under thirty years of age having been rejected. A minimum sentence of a year, however, is made a requisite, the same as obtains at the State Reformatory Prison for Women. It has been found that in many cases several months of confinement are necessary to enable the prisoners to overcome the disturbing effects of the irregularities, alcoholic and otherwise, from which they are suffering when sentenced. Long sentences, with discretionary power given to the local authorities to release a prisoner on ticket of leave for good behavior, have worked favorably in similar institutions elsewhere, and it is believed will give good results in the present instance.

It is understood that the Commissioners of Prisons have established in the reformatory a separate department for men sentenced for drunkenness, so that they will, in the main, be kept by themselves. Heretofore men convicted of drunkenness have been sent to the city or county prisons, to be congregated with the distinctively criminal classes, and for punishment rather than reformation. Here they will be required to work, as they should be, and will have the medical attendance necessary in many cases. It is hoped by the friends of the new measure that the reformatory

will receive a very large number of men who are under the power of the appetite for drink, who have in the past either been let off with fines or sentenced to minor prisons for brief terms. Under the law a man may be sent to the reformatory for a year if he is convicted of drunkenness for a third time within twelve months. The sentence is not a longer one than is frequently necessary to secure reformation, and will ordinarily be reduced by release upon ticket of leave, under surveillance, when it is thought that reformation has been accomplished.

— Considerable surprise and disgust are expressed, and with reason, by a recent writer in the *Polyclinic*, over the rate of medical fees prevailing in certain districts in Scotland where sixpenny charges are made by physicians. An English town of 50,000 inhabitants is also referred to where one shilling charges are made for medical advice. The writer quotes from the *Medical Press and Circular*, of September 11, 1872, page 216, the following charges adopted by a practitioner of thirty years' experience: "Midwifery, two shillings and sixpence; advice, sixpence; consultations, one shilling," and asks: Is there a barrister in England, or an attorney-at-law in Pennsylvania, who accepts such insignificant fees for professional services? We cannot answer for the barristers, but truth compels us to admit that there is, or was a short time ago, in Boston an institution of a quasi educational nature where there is a resident physician (female homœopathic) whose charges for a consultation, including medicine, are twenty-five cents.

— What could be more characteristic of English conservatism than the maintenance year after year, in the same form, of the Harveian and Hunterian orations? The preëminence of these two masters in medicine is not to be for a moment doubted, but what is there new to be said of either of them to a professional audience after the eulogies which have been pronounced for so many successive years? Everything that is knowable about these men has long since been discovered by repeated gleaners in the well-trodden field, and if an orator saves his speech from the trite and commonplace it is only by taking great latitude in his treatment of the subject. If this custom is to be continued as heretofore, a Harveian oration with the Harvey left out will be the only resource left to the speakers. The sameness of these repeated laudations might well give place to the discussion of some timely and vital professional topic. And yet that the lay public have something to learn of Harvey still is shown by a story told in the *Athenæum* of a Spaniard who, after gazing at the façade of London University, pointed to the statue of Harvey and remarked to the friend who acted as his guide: "Just like you practical English, to erect a statue to a man because he invented a sauce."

— In the *Lancet* (May 17, 1884) is reported a case of sarcoma surrounding the heart. The patient was a girl, aged seven years, who had suffered for eight months previously with labored respiration, which gradually became so distressing that orthopnœa resulted. She also had paroxysmal attacks of angina. When seen the pulse was 150, respiration 40, temperature 98.8° F. On the left side of her chest there was a reddish protuberance with varicose veins running over it. Dullness all over the left chest. The first sound of the heart was feeble, the second inaudible. The dyspnœa continued, with occasional attacks of angina, until, about a month from the time she came under observation, an unusually severe attack left her so exhausted that death resulted. *Autopsy.* The heart was surrounded by a growth two inches in thickness, of a yellowish color and firm consistence. The large vessels had been compressed by the growth. The mass extended some distance down the spinal column. Its origin was difficult to trace, but it was supposed to have begun in the thymus gland. Microscopic examination showed it to be a round-cell sarcoma.

NEW YORK.

— At the last meeting of the Society of Medical Jurisprudence and State Medicine, held December 11th, the annual election of officers took place, and resulted as follows: President, Dr. Frank H. Hamilton; Vice-President, the Hon. Amos Hull; Secretaries (recording, financial, and corresponding), Dr. George W. Wells, Max F. Eller, Esq., and Dr. J. F. Chauveau; Treasurer, Dr. A. M. Jacobus. A paper on The Evidence of Experts was read by Mr. Hull, and in the course of it he said that a clamor had been raised against expert testimony on the ground that it was unreliable, purchasable, and corrupt, and he believed that there certainly was cause for complaint. Members of the Bar had placed unscrupulous medical men on the stand as experts in conspicuous cases, and they had failed to show that candor, impartiality, frankness, truthfulness, learning, and ability, which the public had a right to expect. Having alluded to the conflicting expert testimony in the Gosling, Guiteau, and Rhinelander cases, he remarked that lawyers were often too ignorant to examine medical witnesses, and contended that members of the Bar should be able to question an expert witness with a degree of skill which could overthrow his testimony if it were defective. He then condemned the provisions of a law which had been proposed by Ex-Surrogate Calvin for remedying the present evils, according to which judges would have power to appoint experts to the exclusion of all others, on the ground that the Legislature had no constitutional authority to enact such a law, since it would make medical experts public officers and part of the administration of the State, over which the judges had no legal power. In conclusion, he read the draft of a law framed by himself in which it was provided that judges should have the right to enter an order summoning such learned experts as they might deem necessary, but not to the exclusion of others. In the discussion which followed the paper Mr. Jacob F. Millar said that the trouble with experts was that they seemed to think that they went on the stand for the purpose of swearing evidence in behalf of the side which called them; while in reality they had no more to do with either side of a case than did the interpreter who translated a witness's testimo-

ny for the benefit of the jury who did not understand the language in which it was given.

— The twenty-ninth anniversary of the Woman's Hospital was celebrated on the 11th of December. The report of the Secretary of the Medical Board showed that during the year ending September 30, 1884, 630 patients had been treated in the wards and 4180 in the out-door department. The total number of operations performed in the hospital was 516, and the number of deaths was 23. "From a professional stand-point," said Dr. Hunter, "the Medical Board has good reason to be satisfied with these statistics. A comparison with the year preceding shows a larger number of patients treated, a larger number of operations performed, and a smaller number of deaths, — smaller by eight." A number of gifts and legacies were announced as having been received during the year, the largest of which was one of $25,000 from the estate of Ex-Governor Edwin D. Morgan.

— The Commissioners of Charities and Correction sent their annual report to the State Board of Charities at Albany December 10th. There were relieved during the year ending October 31st, including the out-door poor, 48,325 paupers. Five hundred and ninety-six children were born in the poor-house, and there were remaining November 1, 1884, 8273, of whom 3784 were lunatics, 290 idiots, 130 blind, 63 deaf mutes, and 207 epileptics.

— The first number of a new magazine called *Babyhood* has just been issued. Its object is "to gather and present to parents the best current thought on the care of infants and on all topics relating to nursery life," and the medical editor is Dr. Leroy M. Yale. The first number (December) contains articles on Vaccination by Dr. Yale and the Adulteration of Milk by Dr. John B. Isham.

Correspondence.

A PLEA FOR THE USE OF THE CRAYON IN MEDICAL SCHOOLS.

MR. EDITOR, — With the vast strides that medical instruction has taken in the last two decades, it is astonishing that one means to this end has been practically neglected, namely, the crayon with the black-board.

Art is so universal in its applications at the present day, that it is strange that it has not been made to minister in the didactic and clinical instruction of surgical and anatomical lecturers.

There are so many features in the various branches of medicine and surgery that could be so much more intelligently and vividly presented by the crayon than by the dead subject. One of its widest fields of usefulness is in the illustration of surgical anatomy, where you can give life-like representations of the various regions representing the different tissues, arteries, veins, lymphatics, and nerves in their life-like color. Using the crayon in conjunction with the cadaver, in this line of instruction, the conditions during life could be much more clearly set forth.

But in the department of operative surgery its usefulness is much more apparent. Nothing has ever seemed more useless and unsatisfactory to me than the operations performed before a class of medical students, as is done year after year, on the dead human body. Dead flesh cuts so differently from the living, and dead tissues behave so dissimilarly. The veins and the arteries present hardly one feature of their appearance during operations performed in life. While with a fair amount of skill in drawing, an art anatomist, even though he be not a Rimmer, can depict these operations with all the vivid charms of drawing. "Drawing has been termed the grammar of art. The great artists of the Italian and Flemish schools excel their successors more in the beauty and *power* of their drawing than in anything else." With the use of the crayon and the black-board you can so present an operation that you can almost see the flesh quiver and the vessels bleed.

Dissection of the human cadaver is undoubtedly useful and necessary to the student of medicine and surgery, yet the minimum amount that will answer the purposes of thorough instruction is the desirable amount. Maclaise has done much for surgical anatomy in his beautiful illustrations. Bougery has done the most in his superb and life-like delineations of surgical operations, and I see no reason why these should not be equally well produced on the black-board, giving far more power to the instructor in operative surgery: and the teachers of clinical surgery would also augment their powers as instructors by the artistic use of the black-board, not the off-hand use that is now made of it by many teachers. The surgeon who has so drilled his hand and educated his eye as to use the crayon with artistic effect will hereby promote his skill as an operator. It has often been said that the true physician should be master of all sciences. But the surgeon should be more, he should be a good physician to begin with, and a man of mechanical genius and an artist as well. Very truly yours,

GEO. G. HOPKINS, M. D.,
Surgeon St. John's Hospital, etc.

283 LAFAYETTE AVE., BROOKLYN, N. Y.,
November, 1884.

Miscellany.

OBITUARY. — DR. EDWARD JARVIS.

THE late Dr. Eward Jarvis, whose death we have recently recorded, was eminently a philanthropist. Born in Concord of this State, January 9, 1803, Dr. Jarvis died October 31, 1884, two days before his wife, and was buried with her, fifty-two years after their marriage. After graduating at Harvard College, and later at the Harvard Medical School, he began the practice of his profession in Northfield, from which he soon removed to his native town, where he remained a few years, then going to Louisville, Kentucky. There he became deeply interested in the public school question, and after long and patient work succeeded in introducing the system then common in Massachusetts. He also devoted himself to a careful study of insanity, and so clearly pointed out the evils in the asylum treatment of the insane that many of his suggestions for their improvement were adopted.

His next removal was to Dorchester, where he remained until his death, devoting his time until the infirmities of age came upon him to the treatment of

the insane in his home, attaining, by his personal qualities and his devotion to their care, a rare success. Dr. Jarvis was one of the members of the Corporation of the Perkins Institution for the Education of the Blind, where he rendered the late Dr. Howe material aid; he was Superintendent of the School for Feeble-Minded Youths, Trustee of the Worcester Lunatic Hospital, Consulting Physician to the New England Hospital for Women and Children, and for nearly a third of a century President of the American Statistical Association.

Dr. Jarvis was very much interested in all matters relating to the welfare of mankind, and whenever he had the opportunity he enthusiastically devoted himself with a single mind and large heart to furthering the cause especially of public education, State charity, public health, sanitary science, the treatment of the insane, and vital statistics, upon which subjects he was a frequent contributor to the JOURNAL, where, as elsewhere, he showed that his interest in science was chiefly as a means of benefiting humanity. He was the earliest petitioner to the Legislature for a State Board of Health. He labored year after year, early and late, for its establishment, and he did his best to support it by zealous work. His enumeration of the insane in Massachusetts (Report of 1854), his essays on political economy, social science, and statistics, and his valuable contributions to the United States Army Reports gave him a well-deserved reputation as a statistician in this country and in Europe. As a kind-hearted citizen and philanthropist Dr. Jarvis was ever ready with sympathy and help for every person and good cause that needed them, and his public spirit was shown to the last in the gift of his valuable collection of books and reports to Harvard College, the American Statistical Association, and the public libraries of Concord and Boston. He also gave $500 each to Harvard College and the Statistical Association.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 6, 1884.

Deaths reported 2764: under five years of age, 997; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 562, lung diseases 403, consumption 319, diphtheria and croup 273, typhoid fever 70, scarlet fever 48, diarrhœal diseases 45, measles 40, malarial fevers 33, whooping-cough 27, cerebro-spinal meningitis 13, erysipelas eight, puerperal fever four, typhus fever one. From *diarrhœal diseases*, New York 12, New Orleans eight, Chicago seven, Brooklyn five, Cincinnati and Fall River four each, Boston, St. Louis, Providence, Charleston, and Springfield one each. From *measles*, New York 23, Cincinnati seven, Fall River three, Brooklyn and Chicago two each, Baltimore and St. Louis one each. From *malarial fevers*, St. Louis seven, New York and Cincinnati six each, Brooklyn five, Baltimore four, Philadelphia three, Chicago two. From *whooping-cough*, New York 17, Brooklyn, Chicago, and Boston

two each, New Orleans, Providence, Cambridge, and Lawrence one each. From *cerebro-spinal meningitis*, New York seven, Chicago, St. Louis, Cincinnati, Charleston, Worcester, and Springfield one each. From *erysipelas*, New York four, Philadelphia, Brooklyn, Lowell, and Lynn one each. From *puerperal fever*, Brooklyn, Chicago, Cincinnati, and Cambridge one each. From *typhus fever*, New York one.

Cases reported in Boston: scarlet fever 55, diphtheria 40, measles 27, and typhoid fever 16.

In 100 cities and towns of Massachusetts, with an estimated population of 1,307,683 (estimated population of the State 1,955,104), the total death-rate for the week was 19.29 against 18.92 and 15.60 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,762,354, for the week ending November 22d, the death-rate was 20.9. Deaths reported 3512: infants under one year of age 832; acute diseases of the respiratory organs (London) 354, whooping-cough 76, scarlet fever 72, fever 67, measles 59, diarrhœa 40, diphtheria 41, small-pox (London) 33. The death-rates ranged from 17 in Bristol to 26.2 in Preston; Birkenhead 20.1; Birmingham 19.9; Bradford 22.4; Hull 23.9; Leeds 19.8; Leicester 19.6; Liverpool 24.6; London 19.7; Manchester 24.7; Nottingham 25.2; Sheffield 21.4; Sunderland 25.8. In Edinburgh 23.3; Glasgow 29.6; Dublin 32.7.

For the week ending November 22d, in the Swiss cities, there were 21 deaths from consumption, lung diseases 15, diarrhœa 13, diphtheria and croup eight, typhoid fever four, scarlet fever one, erysipelas one. The death-rates were, at Geneva 11.2; Zurich 2.0; Basle 13.2; Berne 25.6.

The meteorological record for the week ending December 6th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps: —

FRANKLIN DISTRICT MEDICAL SOCIETY.

RESOLUTIONS IN MEMORY OF THE LATE CHARLES M. DUNCAN, M. D.

At a quarterly meeting of the Franklin District Medical Society, held in Greenfield, November 19, 1884, exercises commemorative of Dr. Charles M. Duncan, late of Shelburne, were held.

Eulogistic addresses were made by several members present, and the following resolutions were adopted by the Society: —

Whereas as it has pleased our Heavenly Father to remove our much-respected and honored brother, and long-time Fellow of this Society, Dr. C. M. Duncan, who died October 4, 1884, at the ripe age of seventy-six years, falling, as he had often expressed the wish he might do, in the furrow, with the harness on, of the profession he had adorned for more than fifty years;

And whereas, in the death of Dr. Duncan this Society loses its oldest, and, up to the time of his death, most useful and valued member, and the medical profession one of its noblest veterans in caring for, and ministering to, sick and suffering humanity; therefore

Resolved, That in the death of our brother the Franklin District Medical Society loses one of its most useful and esteemed members, and the profession a wise and honest physician.

That, in the record of his long, active, and earnest life, given entirely to the arduous and self-sacrificing service of a country doctor, he has erected a monument to his memory in the hearts of his fellow-men more enduring than any shaft of stone or bronze, and that this Society will ever cherish this record among its richest possessions.

That the memory of his success as a true and scientific physician, without pedantry or egotism, always faithful to his convictions and his patients, will ever stand as a bright and shining example to those of us left behind to do the work that was so well done by him for half a century.

That we extend our deepest sympathy to his bereaved family in this their great loss.

That a copy of these resolutions be presented to his family, and to the County newspaper and the *Boston Medical and Surgical Journal* for publication.

NINTH INTERNATIONAL MEDICAL CONGRESS.

DEATH OF JAMES G. THOMAS, M. D., OF SAVANNAH.

The Executive Committee announces, with great sorrow, the death of Dr. James G. Thomas, of Savannah, one of the members of the General Committee of Organization.

Dr. Thomas took a deep interest in the success of the Congress, and, at a considerable sacrifice, came to Washington, November 29th, to attend the meeting for organization. While on the way he was seized with a violent chill, and on his arrival at once took to his bed, from which he never again rose, the disease proving to be acute lobar pneumonia. He may be said to have lost his life in the service of the Congress, and it is an irreparable loss to it, as well as to his bereaved family and his fellow-citizens of Savannah and of Georgia.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, UNITED STATES ARMY, FROM DECEMBER 6, 1884, TO DECEMBER 12, 1884.

Hammond, Jno. F., colonel and surgeon. Retired from active service, by operation of law, on December 7, 1884, under provisions of Act of Congress approved June 30, 1882. S. O. 287, A. G. O., December 8, 1884.

Irwin, B. J. D., major and surgeon. Granted one month's leave of absence. S. O. 112, Department of Arizona, November 28, 1884.

McKee, J. C., major and surgeon. Leave of absence still further extended one month. S. O. 288, A. G. O., December 9, 1884.

Porter, Jos. Y., captain and assistant surgeon. Sick leave of absence extended four months on surgeon's certificate of disability. S. O. 286, A. G. O., December 6, 1884.

Appointment. — Dr. Charles D. Sawin has been appointed to be physician and surgeon to the Massachusetts State Prison at Charlestown.

THE LIBERATING OF THE RING FINGER IN MUSICIANS BY DIVIDING THE ACCESSORY TENDONS OF THE EXTENSOR COMMUNIS DIGITORUM MUSCLE.[1]

BY WILLIAM S. FORBES, M. D.,

Senior Surgeon to the Episcopal Hospital, Demonstrator of Anatomy at Jefferson Medical College.

When the middle finger and the ring finger are brought down by the flexor muscles, and their balls are held down firmly against the keys of a musical instrument, as in performing on a piano, for the purpose of producing continuous sounds, and at the same time it should be necessary to extend and then to flex the ring finger in order to produce accompanying sounds, it will be found that in the still flexed position of the middle and little fingers the ring finger can be but very slightly extended. Its complete extension, without operative interference, can only be brought about by long-continued exertion in practice, when elongation of certain accessory, but restricting, tendons is made by nutritive change.

To explain the cause of the inability to extend at once completely this ring finger, and to demonstrate the way to remove this cause by a surgical operation of simple moment, is the object of this paper.

In the dorsal aspect of the metacarpal zone in man, dissection shows that the tendon of the extensor communis digitorum muscle that goes to the ring finger gives off a slip on either side, one of which goes to join the extensor tendon of the middle finger, and the other to join the extensor tendon of the little finger. These two slips are known as the lateral vincula or *accessory* tendons. Now while the middle and little fingers are held in a flexed position these accessory tendons, by virtue of their attached extremities, hold in check the extending power of the muscular fibres operating upon the tendon of the ring finger, and thus this finger is restricted in its function of extension to a very limited degree.

These accessory tendons are sometimes found in one hand and not in the other. They exist more frequently in the right hand than in the left. Now and then the extensor tendon of the ring finger splits at the point of departure of the accessory slips and then reuniting leaves a button-hole appearance, and again these accessory slips are entirely absent.

In 1857 Mr. J. D., a young musician and a performer on the piano, consulted me in regard to his inability to *lift up*, as he expressed it, the ring finger of his right hand while the middle and little fingers neighboring were held flexed on the keys of his piano.

This restriction did not exist in the ring finger of his left hand; with it he had no trouble. I explained to him the presence of the accessory tendons in his right hand, with their restricting power, and told him of their probable absence in his left. They could be distinctly felt in his right hand; I could not observe them in the left.

At his desire I performed the operation of subcutaneous tenotomy on the tenth day of November of that year. An incision less than a quarter of an inch in length was made through the skin and fascia just below the carpal articulation of the metacarpal bone of the ring finger, and above the radial accessory slip of his right hand and parallel with, and on the radial aspect of, the extensor tendon of the ring finger.

A narrow, blunt-pointed bistoury placed in this incision, with its handle depressed and its blade flatwise, was carried beneath the accessory slip and down as far as just a little above and between the knuckles of the ring and middle fingers, where its blunt point could be felt beneath the skin. The bistoury was now turned with its sharp edge towards the skin, and the middle finger strongly flexed and the ring finger extended, so as to make tense the accessory slip, when, with a gentle sawing motion, the slip was at once severed. The bistoury, turned flatwise, was now withdrawn through the same opening by which it entered. The accessory slip on the ulnar side of the extensor tendon of this ring finger was divided in a similar manner immediately afterwards by a distinct incision through the skin and fascia on the ulnar side of the extensor tendon of this finger. Not a quarter of a drachm of blood was lost in the two operations. A small piece of adhesive plaster was placed over each incision, and a figure-of-eight bandage was carried around the wrist and hand, leaving the thumb free, and kept on for two days, when the patient was asked to perform on his piano in order to keep the cut extremities of the accessory tendons apart. A slight swelling of the parts existed for less than a week. The liberation of the ring finger was complete. The ball of the finger could be elevated an inch farther from the plane of the hand, and my patient expressed his gratification at the extended and great facility with which he could use this ring finger on the keys of his piano.

In 1881 Mr. Richard Zeckwer, the accomplished professor and director of music in the Philadelphia Musical Academy, called on me and asked me whether I could not cut these accessory tendons. He stated that if they could be cut in some of his students in music that he was sure much time would be saved, and their advancement in music greatly accelerated.

Mr. Zeckwer had been well taught the anatomy of the hand in Leipsic, where he was educated in music, and was well aware already of the restraining force of these tendons. His views were right, in my opinion. He brought to me a young man whose left ring finger was very much restricted, and the tense accessory tendons could be distinctly felt. At the young man's desire I operated at once, and on dividing the tendons of the fingers he could lift this finger from the plane of the hand an inch higher than before the operation.

Since 1857 I have divided these accessory tendons for the purpose of liberating the ring finger in fourteen persons, and in nine of these the operation was performed on the tendons of both hands at one sitting. I do not think at any one of these operations half a drachm of blood was lost. In not one of them did any accident follow the operation. The issue in all of them was successful.

In two persons who came to my office together, strangers from a distance, I performed this operation on the two hands of each of them in the presence of my friend, Dr. Addinell Hewson, Jr. These two patients said, with emphasis, that there was not only relief in using the ring finger, but there was also an absence of exertion, which before the operation was constant and forcible along the back of the fore-arm and hand.

[1] Read before the Philadelphia County Medical Society, November 12, 1884.

It will be observed that in this operation the totality, the complete sum of the power of the extensor tendon going to the ring finger is left unimpaired. Nor does the operation lessen in the least the power of the common extensor muscle to extend the neighboring fingers.

The question may be asked, then, Of what use are these accessory tendons in man? As far as I am capable of observing they are entirely vestigial. Just as we may believe that the plantares are vestigial muscles.

This brings us to look into the comparative anatomy of these accessory tendons, and to examine the entire muscular anatomy of the hand. Professor Owen thus writes in regard to the flexor and extensor muscles in the hand of mammals:[1] "The deep and superficial flexors of the fingers are distinct, but a remnant of that blending which exists in most lower mammals may be seen in the short connecting tendon which in the aye-aye passes from the ulnar belly of the 'flexor sublimis' to the division of the 'flexor profundus,' giving off the tendon to the middle fingers. The fleshy part of both flexors, but especially the deep one, is continued nearer to the hand in *Lemuridæ* and most other *Quadrumana* than in man, thus enabling the muscles to continue their action as finger-benders when the hand itself is flexed. . . . The 'flexor brevis,' the 'abductor,' the 'adductor,' and 'opponens pollicis' are present in the chimpanzee and gorilla, as are likewise the 'extensor longus' and 'extensor brevis.' In the orang these muscles begin to be confounded; in most lower *Quadrumana* they are blended together. The homologue of the 'extensor indicis' of man bifurcates and sends a tendon both to the index and medius digit; the homologue of the 'extensor minimi digiti' likewise splits and sends a tendon also to the annularis; so that while in man the index and minimus only have two extensor tendons, all four fingers have them in most *Quadrumana*. The hand is thereby the stronger as a suspensor of the body from a bough."

In all felines we find that although lateral motion in the hand is restricted flexion and extension are very forcibly made. Thus in the cat we find not only a common extensor, but also a proper extensor to the index, middle, ring, and little fingers. The proper extensors to the index and to the little fingers have their analogues in man in the extensor indicis and the extensor minimi digiti. In man the common extensor tendon of the ring finger gives off lateral branches; in the cat it does not, for here we find a perfect additional organ. We may believe, then, that the accessory tendons going off from the extensor tendon of the ring finger in man are the vestigial remains of muscles which in the lower animals are developed and perfect organs.

The perception of pleasure in the equality of sounds is the principle of music. If the power of producing the equality of sounds is restricted by the vestigial accessory tendons they should be divided, especially as this division is so easily accomplished.

I would divide them just as I would divide the tendon of the internal rectus in certain cases of squint in order to extend the range of vision.

In examining the muscular anatomy of the hand it will be found that flexion and extension are produced not only by those muscles which especially make these motions, but by all those muscles whose tendons pass beyond the radio-carpal articulation. Flexion of the wrist is produced by the radial and ulnar flexors of the carpus, and is aided by the flexors of the fingers when the action of those muscles of the fingers is either completed or is opposed by any resistance, as when the over-extended hand is pressed against a surface in pushing or in the support of the body. Extension of the wrist in a similar manner is accomplished not only by the three muscles specially devoted to that function, — the extensor carpi radialis longior and brevior and the extensor ulnaris, — but also by the extensors of the fingers.

To insure the efficient action of the long extensor and flexor muscles of the fingers it is necessary that there should be simultaneous action of the flexors and extensors of the wrist respectively; for the wrist-joint must be fixed backwards by its extensors in order that the long flexors of the fingers may act. And the wrist must be fixed forwards by its flexors in order that the long extensors may act upon the fingers.

The flexor communis digitorum sublimis and the flexor profundus bend respectively the second and the third phalanges of the fingers, while the extensor communis extends the *first phalanx*. The four lumbricales, on the other hand, and the seven interossei muscles have a double action in consequence of their insertion into the lateral expansions of the extensor tendons, and some of the interossei directly into the base of the first phalanges. This action consists, first, in the flexion of the fingers at the metacarpo-phalangeal articulations, and, second, in extension of the second and third phalanges. The lumbricales and interossei,[2] therefore, are antagonists to both the long flexors and to the long extensor. This partial and combined action of the long and short muscles upon the fingers has been well known for some time, especially as regards the lumbricales, but it has recently been confirmed and elucidated as regards the interossei by the electro-physiological experiments and pathological observations of Duchene.[3]

With respect to the interossei, it is further to be observed that besides being *flexors* of the *first* phalanges, by virtue of their insertion into the base of these bones, and at the same time *extensors* of the *second* and *third* phalanges, by virtue of their further insertion into the lateral expansions of the extensor tendons, they severally exercise an abducting or adducting action on certain fingers or direct them away from or towards the middle line of the hand, according to the places of their respective insertions. And thus the four dorsal interossei are abductors of the index, middle, and ring fingers, and the three palmar interossei are adductors of the index, ring, and little fingers respectively.

THE TYPHOID OF NEW-COMERS.

BY JOHN D. HALL, M. D.,

Assistant Surgeon, U. S. A., Fort Randall, D. T.

FORT RANDALL, Dakota Territory, has in some respects an advantage of location as being remote from the lines of travel. In fact, probably few places exist within a radius of a thousand miles from Chicago so unexposed to the waves of travel and traffic as this post.

Placed in the midst of a big Reservation, and with no settlers for many miles to disturb or contaminate, and with a river wide and deep between it and the ap-

[2] Quain's Anatomy.

[3] Duchene, Physiologie des Mouvements.

proaches of civilization, it is mostly left to the action of such causes of disease as the locality or the people themselves may occasion.

For the simplification of some medical problems such places may have an advantage. Diseases of the contagious class are few and far between. Diphtheria, scarlatina, cerebro-spinal fever, that have been such scourges elsewhere, are here unknown, and, in fact, with the occasional exception of measles, mumps, whooping-cough, and typhoid fever, it may be said the whole fiendish brood of infectious diseases is conspicuously absent.

So accustomed does the mind become in such a locality to trace contagions to the introduction of their specific cause, that in cases affording no clue we are naturally led to the conclusion that these diseases belong to the place, that is, are autochthonous. In this way the writer has been led to infer the spontaneous origin of typhoid fever.

The theory of typhoid originating *de novo* is not a new one, as it has long been advocated by Murchison and others, who refer the causation to the decomposition of filth. How much or how little the power of filth may have to do with it, there still seems room for research. Certainly the connection of typhoid indissolubly with filth (pythogenesis) seems hard to understand in the light of numerous observations, since one often sees the foul products resulting from faulty drainage of weeks' or even months' standing without any concomitant of typhoid, and, per contra, cases of typhoid arising in other places without any fault of drainage really open to criticism.

Here is a post having a water supply of acknowledged good quality, with cleanliness and ventilation carefully maintained in its living rooms, and cleanliness and disinfection in its outhouses. The writer has never known of a case of typhoid fever among habitual residents of the post or vicinity, but occasionally has a case among new-comers. During the last four years there have occurred five cases of typhoid (at long intervals apart), of which four recovered and one died. The writer has notes of the four which recovered, the other was seen only in consultation. There was little danger of confounding these cases with any form of malarial fever. No fact could be much better evidenced than the absence of malaria at this place. No case is remembered as being met with, except here and there the outcropping of preëxisting malaria in the system; and, moreover, such cases have always proved exceedingly mild and tractable, yielding readily to quinine. The cases of typhoid, however, showed no disposition to yield to quinine treatment, had a slow progressive onset, and ran through their tedious weeks with no semblance of remission. One of the cases occurred in midwinter, when malarial causes are supposed to be in abeyance even in their chosen haunts. All of the cases occurred in newcomers, one in the first week, others in the second or third week, and two in the seventh or eighth week after arrival. Unless we suppose an extraordinary period of latency, the last two cases, at least, must have been contracted after arrival. But in what way? Faulty drainage and sewer gas (the supposed root of so much pathological evil); filthy surroundings, and impure water supply may be excluded in a place so isolated, and so hygienically cared for as this. Far apart in time of occurrence, there could be no contagion from one case to another — neither direct nor miasmatic contagion (Liebermeister). Moreover one of the two cases last mentioned was in an officer's family, living in a commodious house, where there had been no cases of serious illness for several years, and have been no other cases since this. This case was that of a boy of thirteen years, delicate, arrived seven weeks before from Camp Lewis, Colorado; the case was of considerable gravity, with a sustained high range of temperature till about the third week, when it began to decrease and oscillate; after four weeks there was a relapse of ten days, and after another interval of improvement there came a second relapse of five days, so that the febrile period covered fully eight weeks, recovery then taking place to extra good and lasting health.

The other of the two cases above referred to was that of a sergeant, named Donovan, who died after two weeks' sickness about two months after arrival from Governor's Island. There were no notes nor temperature charts of this case, and there was no autopsy.

The only theory that seems satisfactory to the writer in regard to these cases is that they are due either to climatic influence, or to that difference of telluric and atmospheric surroundings known as change of climate. Taking the first part of this hypothesis as having the more weight, we would assume that there is a slight tendency towards typhoid at Fort Randall, as also in many other portions of our northern zone, and that here it is never intensified by crowding and neglect, and is just enough to sometimes affect new-comers.

This hypothesis of autochthonous origin of typhoid would also explain such outbreaks as are vaguely called mountain fever and typho-malarial fever. Such fevers are often spoken of and assumed to exist even in localities where the commoner manifestations of malaria, such as intermittents, exist not at all or only in very slight degree.

While at Fort Benton, some years ago, the writer remembers there were reports of typho-malarial fever having caused an endemic among the soldiers soon after their arrival a year earlier. Nothing deserving to be relegated to the nomenclature of mountain fever or typho-malarial fever was seen in the three following years, but several cases were seen which ran the regular course of typhoid (about one or two cases a year), and these were mostly in new-comers.

Recurring to the cases seen at Fort Randall, and particularly the one case most dwelt upon, the question arises, was it typho-malarial, although there was no malaria? Was it mountain fever, although the altitude is only moderate (1200 feet)? Was it pythogenic, although in surroundings remarkably cleanly? Or was it the typhoid due to conditions imperfectly known, incident to climatic influence, and which might be designated The Typhoid of New-Comers?

— There is no new thing, even therapeutically speaking, under the sun, and nerve-stretching turns out to be of respectable antiquity, as a contemporary points out. Philip Doddridge seems to have suggested it early in the eighteenth century, and on rather a wholesale scale. He says: —

"Arise, my soul, stretch every nerve."

REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.[1]

BY E. H. BRADFORD, M. D., AND H. L. BURRELL, M. D.

ACETABULAR HIP DISEASE.

Dhourdin [2] has examined the material at the hospital at Berck and found a number of cases of diseases of the hip-joint where the primary seat of affection appeared to be in the acetabulum. The diagnosis was to a certain extent conjectural, and was based chiefly upon careful palpation within the rectum. The treatment consisted of correction of the distortion under an anæsthetic and fixation of the trunk and limb without extension and excision in the severe cases. The statistics are based upon 237 cases, and show fifty-three per cent. of recovery. Under conservative treatment eighteen per cent. died; four per cent. were improved. Twenty-six patients underwent excision. Fifteen per cent. complete cure; forty-two per cent. incomplete cure; forty-two per cent. mortality. The patients at the hospital at Berck have the benefit of sea air.

PSEUDARTHROSIS OF THE TIBIA.

Hahn [3] describes an ingenious method for restoring the usefulness of limbs greatly shortened by complicated fractures. "The conical extremity of the upper end of the tibia having been removed the fibula is divided at the same level, its lower extremity is implanted in the medullary canal of the tibia, and the lower end of the tibia is refreshed in an oblique direction in order to strengthen laterally the support afforded the fibula."

TREATMENT OF INFANTILE PARALYSIS.

Bernard Roth [4] gives the following as the guiding principles to be followed in the treatment of infantile paralysis: —

(1.) To improve the power of those affected muscles which have still some voluntary power left.

(2.) To prevent the onset of any deformity, or, if this has already occurred, to reduce it to a minimum.

To improve the power of the affected muscles he advises, first, the correction of the lowering of temperature of the limb by hot baths, friction, the wearing of loosely-knitted woolen stockings, or fur-lined cloth leggings. Next, massage or rubbing should be faithfully applied for a half hour or an hour morning and evening. Massage he divides as follows: —

"Kneading," a combination of grasping and large pinching and pressure with each hand, one after the other, so that what is left of the wasted muscle is thoroughly squeezed and moved about. As considerable force is used, the skin should be protected by a lubricant.

"Circular friction by the thumb" is done as follows: The thumb is firmly placed on any given spot, and while considerable pressure is exerted, describes small circles, from left to right, and from right to left. A spot an inch higher or lower or to one side is then treated in the same way.

General friction of the limb he also considers of importance.

Of more importance, however, than massage is the methodical exercise of the muscles which have partially recovered. This is gained by medical gymnastics or the so-called "Swedish exercises." Although faradization is useful it does not compare with the methodical exercise of the muscles.

DIRECT TREATMENT OF SPINAL CARIES.

Mr. Frederick Treves,[5] in a paper read before the Royal Medical and Chirurgical Society, advocates operative interference in cases of caries of the lumbar — and with some reservation — the last dorsal vertebræ, where purulent collections have formed. A vertical incision is made near the outer edge of the erector spinæ; the sheath of that muscle and the quadratus lumborum are cut through; the psoas muscle is incised, and the vertebræ are reached by continuing the operation along the deep aspect of that muscle. By means of this operation the vertebræ can be examined, carious or necrosed bone removed, and a ready and direct exit can be given to all morbid products. If Heuter's statement be true, that the two vertebræ most frequently attacked by caries were the last dorsal and first lumbar, the operation would be of frequent application.

Mr. Treves has operated on three patients, all of whom made a good recovery.

Mr. Richard Davy reports [6] a case of removal of necrosed particles of bone from a diseased vertebræ.

STATISTICS OF SPINAL ABSCESSES.

Before the Royal Medical and Chirurgical Society Mr. R. W. Parker [7] said that out of one hundred and eighty-three cases of caries of the spine, he found nine cervical, eighty-two dorsal, twenty-one dorso-lumbar, thirty-seven lumbo-sacral, and in forty-two cases the position was not noted.

In about eight per cent. of his dorsal cases suppuration ensued, while it was found in thirty per cent. of his dorso-lumbar cases, and in seventy per cent. of the lumbo-sacral.

THE VALUE OF THE PLASTER-OF-PARIS JACKET.

Sonnenburg,[8] after six years of experience with the jacket, and the treatment of 205 cases and 600 jackets, draws the following conclusions: In antero-posterior curvatures he regards extension as dangerous, for example, death by compression of the spinal cord and trachea — by a large abscess which lay along the spine. He thinks that extension causes abscess. He considers that a plaster jacket ideally fulfills the conditions required for an apparatus for scoliosis. Küster has never seen any abscesses which could be attributed to extension.

Israel, Küster, and Eulenburg, Sr., all use the jacket with extension in lateral curvatures.

Eulenburg, Sr., especially decried the use of extension in plaster-of-Paris jackets in angular curvature. In his opinion it did not maintain extension, and the tendency to union was prevented by separation of the diseased surfaces.

Mr. Macnaughton Jones [9] states that his practice is, "In angular curvature, until I believe that ankylosis is complete, and the patient has had all the benefits

[1] Concluded from page 584.

possible from a rigid support, I apply and keep on the uncut plaster or tripolith jacket." He "combines rest in the prone position with the employment of the support." "As a rule in the early stages of Pott's curvature he does not use extension, save in applying the jacket."

ÆTIOLOGY OF LATERAL CURVATURE.

A difference in the length of the lower extremities has long been recognized as causative of this deformity. Henry L. Taylor, in a paper on Primary Crural Asymmetry,[1] reports sixteen cases of crural asymmetry, and demonstrates the strong bias this gives to the production of lateral curvature and obliquity of the pelvis.

PROGNOSIS IN LATERAL CURVATURE.

Pravaz [2] considers the patient's general condition of great importance in the prognosis of lateral curvature. Chlorosis and imperfect nutrition are unfavorable to the reëstablishment of the figure. In general, recovery of the figure is more to be expected in younger than in older patients, but the writer wishes to warn against the prevalent idea that patients will grow out of a curve of the spine. If the distortion is manifest and does not disappear in the horizontal position, careful treatment is necessary. The prognosis in curvature following phthisis is unfavorable, and distortions due to disturbances of muscular action are often very difficult to treat, and rickety distortions are more unfavorable for treatment than those due to a loss of flexibility of the spine in children at the time of the second dentition or puberty. Curvatures submitted to treatment at an early stage, even when quite pronounced, may become corrected provided the patient's general condition is good, the prognosis depending in a large measure upon the amount of rotation of the vertebræ present rather than on the amount of the curve. Curvatures in the lumbar region are less favorable than those in the dorsal region, and curvatures with a long radius are more readily straightened than those with a short.

SPINAL DEFORMITY.

Mr. Arbuthnot Lane [3] describes three distinct forms of spinal deformity occurring among burden bearers. The *first form* occurs in men carrying weights on their right shoulder, as draymen.

A man supporting a weight on his right shoulder, it will be found that his spine forms a large curve with its convexity to the right, and that the upper dorsal and cervical vertebræ are flexed more than normal. There is an accompanying slight rotation of the vertebræ which affects the position of the ribs. By the continual pressure which the weight exercises on the upper two or three ribs on the right side they, acting as levers on the bodies and transverse processes of the vertebræ, rotate the upper three or four dorsal vertebræ towards the left, forming a small curve with its convexity to that side. The situation of the spinous processes is not modified by this relation to any extent. The formation of the upper curve necessitates a compensatory increase in the deviation of the lower part of the spine from the median line with an increased rotation of the bodies of the vertebræ. The form of the bodies and inter-vertebral substances and the position of the ribs on either side are altered by these compensatory changes. In the lumbar region there is no compensatory curve to the left.

Second form. This is when heavy loads are carried on the back. Here the pressure produces compression, changes in the bodies and inter-vertebral substances of the fifth, sixth, and seventh cervical vertebræ, straightening of the upper two thirds of the dorsal spine, marked and progressive lordosis and destruction of the bodies and inter-vertebral substances of the lower dorsal and upper lumbar vertebræ at that part of the spine where the straightened dorsal part joins the lumbar convexity. It produces a form of spondylolithesis.

The *third form* is due to carrying loads on the head. The changes produced are most marked in the cervical spine, where a well-marked lateral curve, with its convexity to the right, is produced. The axis and third cervical vertebræ are frequently fused together, and the bodies and fibro-cartilages of the cervical vertebræ are much modified, especially in the concavity of the curve and between the upper vertebræ. In the dorsal region there are two compensatory lateral curves, the upper being most marked. The convexity of the upper one is directed to the left, that of the lower to the right.

TUBERCLE IN JOINT DISEASE.

Barwell [4] considers that Schüller's (of Greifswald) experiments conclusively prove "that a tubercular state of the body does not produce joint disease. In other words, the earlier phases of joint disease are not tubercular." Schüller injected tuberculous material into the lungs of twenty-four animals (dogs and rabbits), and at the same time, or soon after, inflicted a sharp blow on the right knee-joint. Not a trace of tubercular disease could be found in any of the uninjured joints, and although tubercle completely studded nearly all of the animals' viscera only six injured joints showed suspicious spots, which were described "as perhaps initial tubercle," and some as "heaped-up epithelioid cells" and "colossal giant cells." Barwell clings to the idea of a strumous diathesis, and hence considers the "ambulatory treatment of chronic joint disease the proper one."

CONGENITAL DISLOCATIONS OF THE HIP.

This affection has been extremely intractable to permanent relief.

Esmarch has cured a case by permanent extension. Brodhurst drew the head of the bone into the acetabulum after subcutaneously dividing the tendons of the obstructive muscles. A groin pad and a thigh splint were worn for six weeks, and the patient was able to walk without the aid of artificial support. Dr. Heusner, of Barmen,[5] has placed on record an excision of the hip for congenital dislocation: —

"The operation was done for excessive suffering in the left joint of a girl twenty years of age. The ligamentum teres was absent, the head of the femur was about as large as that of a child of six years, ovoidal in shape, and much flattened, and its surface was uneven, and the neck of the bone formed an obtuse angle with the shaft. The acetabulum was fully developed and of normal size, although its rim was somewhat flattened and polished above and below. The head, neck, and shaft, and nearly an inch of the shaft of the femur

[5] Philadelphia Medical News, 1884, xlv., 463.

having been excised, the acetabulum was made deeper with the chisel and the parts brought into apposition."

After eleven weeks the patient was able, with the aid of a cane, to walk for a half hour without fatigue; the pain was relieved, and a useful limb resulted.

OSTEOTOMY FOR ANKYLOSIS AT HIP-JOINT.

Poore [1] says deformities of the hip-joint which may be relieved by osteotomy may be considered under four heads: —

(1.) After hip-joint disease.
(2.) After rheumatism.
(3.) After unreduced dislocation.
(4.) After fracture united at an angle.

He considers that an angle of 125° with the long axis of the body is the most useful one for a patient's limb; in that he can sit down, walk, or put his shoes on.

The object of an osteotomy he considers is to correct any adduction of the limb and to reduce the amount of flexion to an angle of 125°. Three points of section of the femur are: —

Through the neck;
Between the trochanters;
Below the trochanter minor.

The accidents following osteotomies of the upper end of the femur are few. Out of 148 patients 119 were cured with the limb in good position. Seventeen died, and in twelve the operation failed, making a mortality of 11.48 per cent. In thirty-three cases suppuration is reported, and in only three is any necrosis mentioned. In three cases an Adams operation did not correct, or the deformity returned, and a section below the trochanter minor was performed with success. In one case compression of the femoral vessel, from tilting upward of the upper fragment after a section below the trochanter, occurred. In one severe hæmorrhage happened on the twentieth day after a section through the neck, from either the femoral or one of its large branches, necessitating a ligation of the femoral. The patient recovered.

Maisonneuve is reported to have divided the sciatic nerve during an operation of section between the trochanters through a large wound.

Many of the operations were performed before experience had demonstrated the proper ones for section. Hence the rate of mortality.

OSTEOTOMY OF THE HIP.

C. B. Keetly [2] has reported ten osteotomies of the hip. Six were done above the trochanter, and four below it. Nine were for ankylosis, one was for an irreducible dislocation. All were done with the chisel and mallet, and under strict Listerian methods. The dressings were changed at most once, or not at all. In two cases drainage tubes were used and necessitated more frequent changes of dressing. One recurrent hæmorrhage occurred. All did well. There was but slight constitutional disturbance.

Each patient was kept in bed six weeks, and allowed to discard crutches and sticks in a few weeks.

GENU VALGUM.

MacEwen [3] has performed osteotomy for genu valgum 820 times. Death has followed the operation in five cases, but in no one instance was it directly traceable to the operation. Suppuration occurred in eight instances; but during the last three years in all the cases the wound has healed without the formation of pus.

In all the cases the operation has corrected the deformity and improved the strength and utility of the limb.

A relapse even to a slight extent was noticed in only one case. The earliest age at which MacEwen has operated is seven years, and the oldest forty-seven.

The average duration of treatment is six weeks in the splints and four weeks convalescing and learning to walk. Combining his own cases with those of British surgeons he has 1384 limbs operated upon by the supra-condyloid method. Three deaths directly traceable to the operation have occurred. Two from septicæmia, the third from a cause not stated.

Howard Marsh [4] reports a case where the anastomotica magna was wounded. The incision was made in the usual position for a MacEwen's operation in a child aged seven. Recurrent hæmorrhages took place, and on the seventh day Mr. Marsh enlarged the wound and came at once upon the anastomotica magna, in the side of which an oval opening was plainly seen from which the blood was freely escaping. The vessel was completely divided, ligatured; bleeding ceased and never returned. The child made a good though slow recovery.

Mr. McGill [5] records a case where the femur was divided transversely above the condyles. A hæmorrhage occurred on withdrawing the chisel a second time, which was controlled by pads. In three hours the blood oozed through the pads. The dressing was removed. The popliteal space was found much distended. An incision five inches in length was made over the outer border of the semi-membranous muscle, exposing the artery. The artery was found completely divided. The two ends were secured with catgut. The case recovered.

At the Annual Congress of French Surgeons [6] Boeckel reported twenty osteotomies and twenty osteoclases for genu valgum.

The results were uniformly good. In his osteoclases he had three accidents, namely, a rupture of the external lateral ligament, a suppurative periostitis, and an incurable pseudarthrosis.

Lumniczer [7] has successfully treated a case of pronounced double genu valgum, in a patient nineteen years of age, by osteotomy of the tibia in one limb, and fixation of the other limb by a plaster-of-Paris in a flexed position for nine weeks. (Hueter's method.) The limbs were found straight, and the deformity had not reappeared in a year.

OSTEOCLASIS FOR GENU VALGUM.

Polaillon and Gillette [8] report successful cases of rectification of osteoclasis (with Collins's apparatus) for the correction of genu valgum in patients fifteen and eighteen years of age, the fracture in both cases occurring at the point of election (that is, above the condyles), and without relaxation of the ligaments.

MM. Rolin and Molieré have an osteoclast whereby the femur may be broken two fingers' breadths above

the knee-joint, and the joint is not in the least degree affected. They state "that after the fracture an interval of at least three days should elapse before the limb is straightened.

OSTEOTOMY AFTER A BADLY UNITED FRACTURE OF THE FEMUR.

Lumniczer[1] corrected a severe deformity in the femur consisting of a sharp angle in the upper third of the femur. The operation was performed four months after the fracture, and was performed under strict antiseptic precautions. The deformity was corrected, union by first intention took place, and eight weeks after the operation the patient was able to walk about upon crutches.

Reports of Societies.

ADJOURNED CONFERENCE OF STATE BOARDS OF HEALTH AT WASHINGTON, D. C., DECEMBER 10, 11, 12, 1884.[2]

THE Conference of State Boards of Health, adjourned from a previous meeting held at St. Louis in October last, met at the Ebbitt House in Washington, D. C., on Wednesday, December 10th, at ten A. M. The call for this meeting included an invitation extended to the principal local boards of the United States and Canada.

THE ROLL-CALL.

The following States and cities were represented and answered the roll-call: —

Louisiana: S. R. Oliphant, S. S. Herrick, New Orleans. • Indiana: Dr. E. S. Elder, Secretary of the State Board, Indianapolis. Illinois: Dr. J. H. Rauch, of Springfield, Secretary of the State Board. Georgia: J. T. McFarland, Savannah. Connecticut: C. A. Lindsley, New Haven. Kentucky: Dr. J. N. McCormick, Secretary of the State Board; W. L. Breyfogle, Louisville. Michigan: H. B. Baker. West Virginia: James E. Reeves, President of the American Public Health Association and Secretary of the State Board of Health; Dr. T. A. Harris, Parkersburg, President of the State Board of Health. Wisconsin: J. T. Reeve, Secretary of State Board of Health. District of Columbia: Dr. Smith Townshend, Health Officer of the District and chairman of the local committee. Texas: William Perry, Galveston. Missouri: J. W. Jackson, Kansas City; J. C. Hearne, Hannibal; Joseph Spiegelhalter, Health Officer of St. Louis, and Dr. Outtan, of the St. Louis Board of Health. Pennsylvania: Crosby Gray, Pittsburg; E. W. Germer, Erie. Ohio: C. W. Rowland, Cincinnati, and A. H. Iddings, Dayton. North Carolina: Dr. Thomas F. Wood, Wilmington, Secretary of State Board of Health. New York: Dr. Joseph H. Raymond, Health Officer of Brooklyn; A. C. Mercer, Syracuse; Erastus Brooks, first Vice-President of the American Public Health Association, and also Chairman of the Conference of the State Boards and member of the State Board of Health, and Dr. W. M. Smith, New York City. New Jersey: Dr. Ezra M. Hunt, Secretary of State Board of Health. New Hampshire: Dr. Irving A. Watson, Concord, Secretary of the American Public Health Association, and also Secretary of the State Board of Health. Maryland: Dr. Charles W. Chancellor, Secretary of the State Board; Dr. James A. Stuart, Baltimore. Massachusetts: Dr. Henry P. Walcott, Chairman of Health Department; Dr. S. W. Abbott, Health Officer; Surgeon-General Holt, of Cambridge, and Dr. S. H. Durgin, of Boston, Health Officer. South Carolina: Dr. Horlbeck, Health Officer of Charleston, and J. Ford Prioleau. Canada: A. B. LaRoque, Montreal; Dr. Frederick Montizambert, Quebec, delegate from the Provincial Government of Ottawa; Dr. Covernton, of Toronto, representing the Government of the Dominion of Canada. Tennessee: G. B. Thornton, Memphis; Dr. J. B. Lindsley, of Nashville, Treasurer of the American Public Health Association, and Secretary of the State Board; Dr. Charles Mitchell, of Nashville, member of the State Board. Minnesota: Prof. Charles

[2] Specially reported for the JOURNAL

Hewitt, of Red Wing, Secretary of the State Board. Michigan: Dr. H. B. Baker, Secretary of State Board of Health. Richmond, Va., Dr. J. G. Cabell. Toronto, Dr. Cunniff.

THE PRESIDENT'S ADDRESS.

The President, HON. ERASTUS BROOKS, of New York, opened the meeting by an address stating the objects of the Conference: —

First. To hear reports from States and cities as to present sanitary conditions.

Second. To consider the best measures for the prevention of cholera in the United States and Canada.

"We regret," he said, after referring at length to the importance of preparing to meet the cholera, "to read the statement of Dr. Hamilton to the Supervisor-General of the Marine Hospital, made far in advance of the present meeting of this Conference, that 'the health boards here in session in Washington said all there was to say at St. Louis.' We also regret Dr. Hamilton's statement that the more recent Conference of 'sanitarians in New York City decided that they wanted no more governmental aid than is now being provided.' Such was not the judgment, conclusions, or record of either of the two bodies in session at St. Louis in the month of October. Nor was it the judgment of the Conference of sanitarians held two weeks since in the city of New York. Upon the contrary, these three bodies, composed of practical sanitarians, expressed the opinion that more and better work could be done by the government to arrest, and if possible prevent, the appearance of a fatal calamity than had hitherto been accomplished. While it may be self-conclusive to a single officer of the government that his own work is complete, and that all other advice, knowledge, and assistance is uncalled for or unnecessary, it is the judgment of your presiding officer, and he presumes of this Conference upon the best information they can obtain, that in a crisis like the present a more enlarged, liberal, and comprehensive system of health administration is necessary for the country than is at the present time provided for by Congress or by one officer or department of the government."

APPOINTMENT OF COMMITTEES.

On motion of DR. WALCOTT, of Massachusetts, the following committees were appointed: —

On Federal Legislation. Drs. Walcott, of Massachusetts, W. Smith, of New York, Rauch, of Illinois, Herrick, of Lousiana, Baker, of Michigan, Brooks, of New York, and McCormack, of Kentucky.

This committee was subsequently enlarged by the addition of the following: Drs. Hearne, of Missouri, Wood, of North Carolina, Chancellor, of Maryland, Elder, of Indiana, and Thornton, of Tennessee.

On Matters pertaining to the Hygiene of States. Drs. Watson, of New Hampshire, Hunt, of New Jersey, Hewitt, of Minnesota, Thornton, of Tennessee, Hearne, of Missouri, and Covernton, of Canada.

On Municipal Hygiene. Drs. Raymond, of Brooklyn, McFarland, of Savannah, Durgin, of Boston, Breyfogle, of Louisville, Montizambert, of Quebec, Spiegelhalter, of St. Louis, and Mr. C. W. Rowland, of Cincinnati.

The Chairman proposed that the Committee on Federal Legislation should consider the subject of reduction of postage on all documents relative to public health issued by State authorities.

Several papers were then presented by representatives of Indiana, Kentucky, and New York Boards of Health, and, with the exception of the latter, were referred to the Committee on State Action.

DR. WM. SMITH, Quarantine Officer of the port of New York, read a paper on

THE FAILURE OF MARITIME SANITARY REGULATIONS.

Dr. Smith gave a summary of the statistics of immigration from 1819 to the present year. He stated clearly the relations of the subject of immigration to the introduction of infectious diseases, illustrating the liability of the immigrant to be the medium of such communication in consequence of his habits at his departure, during the voyage, and at his arrival. The imperfection of present regulations was shown, and the comparative value of consular bills of bills of health as contrasted with those of local authorities. Dr. Smith emphasized in strong terms the need of better trained and experienced medical officers on board transatlantic steamers, who should supervise the sanitary condition of ships, their cargoes, crews, and passengers, and all matters pertaining to the hygiene of sea-going vessels. He also cited instances illustrating the want of intelligence and experience on the part of such officers, particularly in regard to the diagnosis of infectious diseases, isolation, disinfection, and ventilation.

DR. COVERNTON, of Toronto, stated that the present epidemic of small-pox in Canada was traced to infection from an immigrant boy.

Before the adjournment of the morning session an invitation was announced from Surgeon John S. Billings to visit the Army Medical Museum, where specimens of the comma bacillus and the bacillus tuberculosis were on exhibition.

AT THE EXECUTIVE MANSION.

During the recess at noon the members of the Conference went to the Executive Mansion, and were introduced to President Arthur and also to Secretary Frelinghuysen by Medical Director Gihon, of the Navy.

CHAIRMAN BROOKS briefly stated to the President the objects of the Conference, and commended his reference to the subject of cholera in the annual message, and urged the necessity of legislation.

PRESIDENT ARTHUR replied expressing his hearty sympathy with the objects of the Conference, and also stated that the matter in hand was already under consideration by the Secretaries of State and of the Treasury. He also inquired whether it were desirable to present the subject for the consideration of any congressional committee.

DISINFECTANTS.

At the afternoon session the Chairman of the Committee on Disinfectants (appointed at St. Louis in October), SURGEON STERNBERG, made a report of the progress of the Committee.

The Committee was divided into sub-committees on experimental research, the practical application of disinfectants, and the literature of the subject.

The experimental work, in charge of Dr. Sternberg, is conducted at the Biological Laboratory of the Johns Hopkins University at Baltimore. The work at present being confined to the examination of commercial disinfectants, the first test employed is a given quantity of beef tea, a definite amount of each disinfectant being used in the performance of the test, after which it is

proposed to employ well-recognized disease germs, such as the bacillus of anthrax, etc. Many of the popular disinfectants have already been tested, such as Squibb's coal-tar disinfectant, girondin, phenol, Williamson's disinfectant, Platt's chlorides, Labarraque's solution, etc. Dr. Sternberg attributed to the latter officinal preparation a higher disinfectant or germicide potency than has ordinarily been accredited to it.

DR. RAYMOND gave a brief report on the practical application of the subject.

DR. ROHÉ reported that $425 had been contributed by State and local Boards for the work of the Committee, and that $1000 was necessary to defray its expenses.

INTERNATIONAL COMMITTEE.

DR. REEVES, of West Virginia, offered a resolution that measures be taken for the formation of an international committee, composed of representatives from each maritime nation, who should take cognizance of all matters relating to shipping and the water-carriage of persons and cargoes.

This resolution was referred to the Committee on Federal Legislation.

The remainder of the afternoon session and most of the morning of Thursday was occupied in hearing the

REPORTS OF STATE AND LOCAL HEALTH OFFICERS,

some thirty-five or more in number, as to the measures taken and in progress for the purpose of resisting the approach of cholera. The majority of the reports were verbal, and evinced a deep interest on the part of health authorities throughout the country in the objects of the Conference. Some of the reports consumed much time upon irrelevant matters, and others deserve special notice for points of excellence embraced in them.

DR. RAUCH, of Illinois, reported that the State Board had received returns from 420 towns and villages as to sanitary condition, and said that a systematic survey of the State would be made, and efforts also would be made to remedy all defects in statutes relative to public health. He also said, "We propose to place Illinois in a condition to take care of itself if the general government does not do its duty.

DR. MCCORMACK, of Kentucky, reported that a sanitary survey of the State had already been made.

The condition of Boston and Cambridge was clearly stated by DRS. DURGIN and HOLT, of those cities.

DR. REEVES, of Wheeling, West Va., reported the condition of that city, especially with reference to the danger incident to pollution of its water supply.

DR. RAYMOND, of Brooklyn, N. Y., presented a carefully prepared report as to the condition of that city, and the measures which had been taken there for the prevention of cholera. In summing up his report certain definite measures were advised, as follows: —

(1.) The abolition of pump wells in cities.

(2.) The abolition of privy vaults wherever sewer connections could be made.

(3.) The filling and disinfection of stagnant ponds or pools.

(4.) The supervision of sewers and plumbing.

(5.) Inspection of tenement-houses.

(6.) Inspection of food supply, especially of milk, meat, and vegetables.

(7.) Removal of garbage and kitchen refuse.

(8.) Garbage not to be used for filling vacant lots.

(9.) The attention of all public institutions to be directed to the necessity of cleanliness.

(10.) The necessity of taking every possible measure for the prevention of cholera, and of giving immediate notice to health authorities in case of local outbreaks.

THE CUMBERLAND EPIDEMIC.

A special report was read by DR. MCCORMACK, of Kentucky, embracing the result of an investigation by Dr. J. H. Carson in relation to the recent epidemic which had prevailed in the eastern or Cumberland region of that State. He concluded that the disease was epidemic dysentery. That its cause was not a mineral poison, but rather a specific malarial poison due to drinking the water of stagnant pools in a dry season. Public accounts had been greatly exaggerated, and the deaths in Kentucky had not been more than two hundred and twenty-five.

DR. ARBEELY, a native Syrian physician, from Damascus, detailed his experience with cholera at Beyrout and Damascus, and attributed much of the fatality to intemperate habits.

At this point a telegram was read from an importer of rags to the effect that there was no instance on record of cholera infection through the medium of rags.

MR C. E. O'HARA, of the Seymour paper company, stated that they employed two hundred hands in sorting rags at their factory at Windsor Locks in Conn., and no case of cholera had occurred among them in thirty years.

REPORTS OF COMMITTEES ON STATE AND MUNICIPAL ACTION.

The Committee on State Action then reported that the laws of the States are so diverse that it was difficult to formulate a system of uniform action. Each State should be fully advised of the conditions prevailing at the ports of neighboring States through which disease might gain admission to its own cities. In reference to interstate communication it is essential that officers of State and Federal Boards in adjacent States should promptly notify each other of any case of cholera occurring in its own domain.

It is also essential that local boards shall determine in advance how the first cases shall be cared for, so as not to lose valuable time and allow the disease to gain a foothold. It is the judgment of the committee that the time has come when the State Health Boards should be recognized in some national form as having authority to indicate what sanitary measures are necessary, and secure the same through these departments of the government under which they would naturally fall.

The Committee on Municipal Action presented a report embracing the ten propositions already stated in Dr. Raymond's report upon the sanitary condition of Brooklyn, together with an eleventh proposition of a more general nature, urging upon municipalities the importance of prompt measures for the amelioration of all unsanitary conditions.

DR. BAKER, of Michigan, moved that the legislatures of States should be recommended to enact bills providing for contingent funds to be used in the event of an outbreak of cholera. This resolution was referred to the Committee on State Action, and afterward incorporated in their report by vote of the Conference.

REPORT OF COMMITTEE ON FEDERAL RELATIONS AND LEGISLATION.

The Conference reassembled at 4 P. M., and after preliminary discussion on the publication of the pro-

ceedings of the Conference. DR. WALCOTT, of Massachusetts, made a partial report from the Committee on Federal Relations and Legislation, that the draft of a bill had been prepared which needed more consideration and examination, and commented on various sections. He thought the collection of foreign statistics should be by consular officers through the State Department.

DR. CHANCELLOR, of Maryland, offered the following resolution: "That so much of the report on federal legislation be referred back to the committee, and the committee be increased by five, and the committee be directed to urge on Congress a bill providing for the organization of a health department of the United States.

The principal features of the report on federal legislation as finally adopted were published and commented on in the JOURNAL'S editorial columns, December 18th.

DR. SMITH, of New York, from the Committee on Legislation, offered a resolution, which was adopted, providing an international health committee, to be of three members appointed by the Secretary of State, who shall correspond with foreign health officials, and that a conference of Boards of all maritime nations be asked for by the President of the United States, which conference shall adopt rules for carrying and inspection of ships and passengers.

The Conference then adjourned, at 5.30 P. M., to meet at the call of the President.[1]

AMERICAN PUBLIC HEALTH ASSOCIATION.

MEETING OF THE EXECUTIVE COMMITTEE.

The Executive Committee of the American Public Health Association, which was appointed at the annual meeting held in St. Louis, in October last, met December 11th at the Ebbitt House, Washington, Dr. Reeves, President of the Association, presiding, and Dr. Irving A. Walton, secretary. Eleven members of the committee were present.

Arrangements were completed for the holding of the thirteenth annual meeting of the Association at Washington the second Tuesday in December, 1885, and a local committee was appointed, with Dr. Smith Townshend as chairman, and J. Cooper McGinn, Esq., as secretary.

Subjects were selected for competition for the Lomb Prize Essays as follows: (1) Healthy Homes and Food for Working Classes; (2) Sanitary Necessities and Conditions of School Life; (3) Disinfectants; (4) Life-Saving Appliances in Certain Occupations. The full text of the subjects as they are to be treated will be published at an early date. These essays are for prizes of $500 each, and the competition is not confined to members of the Association, but is open to all citizens of the United States.

The Committee on Disinfectants, consisting of Major George M. Sternberg, U. S. A., Dr. J. H. Raymond, Brooklyn, and Dr. George H. Rohé, of Baltimore, was authorized to prepare a preliminary report as soon as possible for publication, in view of the anticipated advent of the cholera next year. It was decided to incorporate the Association under the United States laws relating to the District of Columbia. The committee adjourned to meet in New Orleans next April.

[1] Notwithstanding especial care to secure correctness in our report of the Conference of State Boards of Health at St Louis, statements were attributed to Dr. J. H. Rauch, as he assures us, incorrectly. Our readers are referred to his Address as subsequently published in pamphlet form. — ED.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

C. B. NANCREDE, M. D., RECORDER.

THURSDAY evening, November 13, 1884. The President, DR. SHAKESPEARE, in the chair.

SOME STUDIES ON THE MICROCOCCUS OF THE PLEURO-PNEUMONIA OF CATTLE.

By THOMAS D. DUNN, M. D.

On September 25, 1883, through the kindness of Dr. Bridge, Assistant State Veterinary Surgeon, and Mr. Thomas Edge, Commissioner of Agriculture, of Pennsylvania, I was invited to be present at an autopsy on some cows suffering from pleuro-pneumonia. Their condition being such that recovery was deemed impossible, Mr. Edge ordered them killed. As a description of the macroscopic and microscopic conditions of the lungs was read before this Society a year ago, and as it would have no special bearing on the bacterian nature of the disease, a detailed account will be omitted. Suffice it to say the lung is completely solidified, the air cells filled with effused blood, serum, and lymph, which usually extends into the small bronchial tubes. Portions of the consolidated lung and blood from the heart were placed in a bottle which had been thoroughly cleansed, and the bottle closed with a ground-glass stopper. These were examined microscopically by Dr. George Martin and myself, and were found swarming with germs — micrococci. These little bodies, although seen distinctly with a power of 670 diameters, are best studied with a power of 1000. They are colorless, globular, or oval in form, outline regular, and refractive power notable. The Brownian movement is marked; this is a tremulous motion not peculiar to micrococci. It is common to inorganic particles as well as minute vegetable and animal organisms. They do not seem to move in a manifest manner independent of the currents of liquids in which they exist. They measure from a third to a half micromillimetre or from $\frac{1}{6000}$ to $\frac{1}{8000}$ inch in diameter. They are not dissolved by ether, alkalies, or acids, and take the staining of aniline colors slowly. I have, however, succeeded in staining them by first treating with aqua ammonia, then with staining fluid, and afterwards washing with a weak solution of nitric acid. They have recently been more satisfactorily stained by a two per cent. alcoholic solution of methyl violet. They multiply in nitrogenous culture fluids at ordinary temperatures by millions. They are generally separate, though sometimes united in pairs and little cellular colonies forming distinct zoögloea. From the fact of their being occasionally seen in pairs it is reasonable to suppose that multiplication is taking place. They resist putrefaction, for the cultivation tubes started September 26th swarmed with them two months later. When the nitrogenous material is exhausted their growth is stopped, and they remain in a latent state, as it were, until additional food is given, or they are transplanted into fresh fluid. After the tubes stand a few weeks, the membrane formed on the top sinks to the bottom and the liquid above clears. That they are not dead, but only in a state of repose, is evident from the fact that they multiply anew when inoculations are made from them, but less rapidly than inoculations from more recent cultures. Dr. J. J. Woodward, U. S. A., presented at a meeting of this Society in 1861 a pleuro-pneumonic lung, and mentioned certain "spores of fungi" found in both the healthy and diseased lung, but he did not describe

them. These "spores of fungi" are probably the micrococci under consideration. Aside from this I have not found any record of them, but unfortunately I have not had access to the literature pertaining to this subject.

The following culture experiments were made with the serum virus taken from the diseased lung: The culture fluid consisted of extract of fresh beef, made by chopping it fine and pouring over it hot water. After maceration the juice was expressed and the extract boiled for several minutes. It was then filtered and again boiled to thoroughly destroy all germs. It was then placed in culture tubes which had been washed in a solution of corrosive sublimate, and afterwards boiled. The tubes were closed by absorbing cotton which was sterilized with corrosive sublimate and the application of dry heat. After the culture fluid in the tubes had cooled a minute quantity of the serum was introduced by a small knife whose blade had been heated in a spirit lamp. The tubes were then placed where the temperature ranged from 90° F. to 120° F. On examination of these tubes on the 28th the liquid was found turbid, a thin membrane formed over the surface, and there was a slight deposit. Under the microscope thousands of micrococci were seen.

From this cultivation a second was made and after standing forty-eight hours the surface membrane, cloudiness of fluid, and slight deposit appeared, and myriads of micrococci were found. From this a third generation was started in which appeared a few bacilli — the first discovered.

They are very active colorless bodies, measuring from three to five micromillimetrés in their long diameters, and from one third to one half in their short. Their movements are at times rapid, again they are in a state of repose. Sometimes one will remain a long time motionless, then suddenly dart across the field of the microscope, setting many of its fellows in motion, who seem to catch the spirit of the active bacillus. At one time they advance with the rapidity of an arrow, then retreat or describe circular lines. It was noticed in those cultivations in which the bacilli were found the surface membrane was thicker and more tenacious. In cultivations conducted at a lower temperature the development of micrococci was not so rapid. Fearing that some atmospheric germs might have been introduced with the culture other cultivations were begun from the second generation, in which no bacilli were found. The culture fluid was boiled at intervals to kill germs that might develop from spores not destroyed by previous boilings; and as a further test non-inoculated tubes were placed by their side. In forty-eight hours the former were swarming with both bacilli and micrococci, while the non-inoculated ones remained clear for ten days. These subsequently developed germs after inoculation.

A second series of observations was commenced with fresh virus obtained October 4th. The first and second cultures were pure, but in the third bacilli appeared, and in the fourth they had greatly increased.

It is difficult to explain the relation these forms bear to each other, as to whether the bacilli are organisms developed from the micrococci — the latter being in a sporal stage of their growth — our investigations will not justify a positive answer. Koch has determined that the bacilli of anthrax develop veritable spores and they in turn develop bacilli. Several other observers hold this view, and according to the investigations of Koch, Cohn, and Pasteur upon the development of bacteria it is probable that the spores of bacilli and other bacteria are identical with micrococci in form, aspect, and behavior toward chemicals. In those diseases in which certain bacilli and micrococci are found to be the virus, it is impossible to distinguish them from harmless ones by their microscopical appearance, that is, a specific disease germ can only be determined by its effects on living organisms. The micrococcus of pleuro-pneumonia, so far as present observations go, is identical with that of diphtheria, chicken cholera, and the recently discovered micrococcus of scarlet fever. It is further found that the germ of virulent matter rendered harmless by attenuation does not differ microscopically from the unattenuated which destroys life. I have made no inoculations on animals with the micrococcus of pleuro-pneumonia, but a few cows have been inoculated by others without any reference to a special virus or cultivation of the germ, and the disease was transmitted. However, several experiments have been made in view of destroying the germ, the results of which I will briefly state: A tube containing cultivated micrococci was boiled, and from it a second was inoculated. In thirty-six hours the tube contained many micrococci showing that the germ is not destroyed at 212° F. A culture fluid to which had been added ten per cent. of alcohol was then inoculated. No micrococci had developed a week later. One and one-half per cent. of benzoic acid with borax to dissolve was then added to a culture fluid. Neither micrococci nor bacilli had appeared six weeks afterward. Another culture was started to which was added corrosive sublimate in the proportion of one half grain to the ounce. In three weeks there were no traces of germ life. To test the influence of cold on these organisms a tube containing cultivated germs was frozen, and from this sterilized liquids were inoculated. In forty-eight hours they contained myriads of micrococci and a few bacilli. A portion of diseased lung was frozen, and inoculations from this grew in about the same time. It was afterwards found that the cotton which had been sterilized by heat and corrosive sublimate had been inadvertently exposed to old cultivations and decomposing organic substances, and it is possible that bacteria were introduced by it. When I repeated these experiments it was found that while inoculations from non-frozen virus develop micrococci in a few hours, it requires several days for sowings from frozen specimens to grow in the same culture fluid and under the same conditions of temperature. Whether they were not exposed to cold long enough to destroy the germs or the influence is only sufficient to render them inactive, further investigations will be required to determine. It is my impression that cold will check the spread of the contagion, but not destroy it altogether, and that when the disease once attacks an animal cold will have no influence upon it, though it may prevent the spread of the infection to others in the same herd. The power of medicinal agents to control the disease seems to be very feeble. It would appear that corrosive sublimate, alcohol, and benzoic acid arrest the growth of these germs, but whether doses sufficient to destroy them can be administered without endangering life our veterinary surgeons must determine.

(To be concluded.)

PHILADELPHIA COUNTY MEDICAL SOCIETY.

REPORTED BY G. BELTON MASSEY, M. D.

NOVEMBER 12, 1884.

DR. WM. S. FORBES read a paper on

CUTTING ACCESSORY TENDONS OF EXTENSOR COMMUNIS DIGITORUM.[1]

DR. JOHN B. ROBERTS, in opening the discussion, said: I have been greatly interested in hearing the account of the operation given. Since student days it has been in my mind, but I never happened to be called on to perform it. It was then taught as advisable and looked on as justifiable, and I now know that this suggestion must have come from Dr. Forbes. I have often tried to figure out a reason for these slips, and the disposition has been to regard them as analogues of structures found in lower animals, as Dr. Forbes holds. We have special extensors for the index and little fingers, and I have seen, on rare occasions, a special extensor for the middle finger, but I have never heard of a special extensor for the ring-finger.

The remarks on white fibrous tissue are interesting. The actions of this tissue are most important in holding the various organs of the body in place. It is at times, however, a surgical disadvantage, as, for instance, in the case of abscesses, where the pus being confined by the density of this tissue does harm by more or less extensive burrowing. In binding down tumors and thus causing pain by pressure upon the nerves, and in causing suffocative pressure in bronchocele, it also demands operative interference. We can often relieve pain and asphyxia caused by pressure of this tissue by free incisions made subcutaneously or openly.

I shall be glad to hear further as to the time-test of these cases; and also whether the uncut tendon is made more pliable by actual stretching after long months of piano practice. It would seem to me that there was no stretching of this tendon possible, but that practice caused only a lateral movement of the contiguous tendons and thus permitted a greater freedom of motion in the finger. If this increased motion is possible, then how much time is gained by the operation? The operation itself must be a very simple one, and there should be very little danger of the tendinous bands uniting again.

DR. H. A. SLOCUM: As there will probably be many ladies undergoing this operation, a pertinent question is, How much of a scar does it leave?

DR. DE FOREST WILLARD: Some years since I heard that this operation had been performed for pianists, but did not know the exact details of results desired until this evening. The only danger would be that too deep a cut might divide fibres of the dorsal interossei, muscles which are of especial service to the musician, since extension and flexion of the first phalanx are important actions. These accessory tendons, as seen in the dissecting-room, are sometimes variable in their position, but the operation seems simple, and from the excellent results which I am accustomed to secure by subcutaneous divisions of fasciæ and tendons, I am inclined to favor the procedure of the lecturer.

DR. SHAKESPEARE: In connection with Dr. Forbes' incidental reference to Wickersheimer's preservative fluid, I would like to ask him if he has had any success in its use. I have myself made trial of it, as made here, after the formula published by the Government, and have, in every instance, failed to get good results when using the fluid as an injection. I do not know of any successful results out of Germany, and do know of many failures. The suggestion has been made that there is a secret yet held back by the inventor. On the contrary, with the fluid for immersion, moderately successful results have not been very difficult to obtain.

DR. H. H. SMITH: This operation, and the advantages to be gained by a free use of this finger, are both altogether new to me. As Professor Zeckwehr is present, I hope he will state its value to the pupil, and whether it is better than the ordinary ring and elastic cords used by beginners.

DR. O'HARA: I think it odd that no mention has been made of females being operated on for this condition. Is it possible that a vestigial condition remains with man, and woman does not share it? There are so many more women than men playing upon the piano, it would appear that the ring finger was freer with them than with men.

PROFESSOR ZECKWEHR, speaking by request of the Chair, said: Pianists find great difficulty in performing, owing to their inability to extend the ring-finger. It takes a long time to remedy the difficulty to any extent by practice. With the palm down it can be raised but a short distance. The natural strength of this finger is not so great as that of the others. My pupil, on whom Dr. Forbes operated, gained in a quarter of an hour what I had not accomplished by twenty-five years' practice; before the operation he could raise the finger a quarter of an inch — after it, an inch and a quarter, a gain of a whole inch in a few minutes. I surely think the time gained a great advantage to piano pupils.

DR. CARL SEILER: I am not a practical musician, but would ask if there was a great improvement in touch to be gained by this operation. I have noticed in what might be called one school of musicians, that the motion from the fingers was taught, while another taught motion from the wrist. The question is æsthetic: Can we gain a better touch by severing these bonds?

PROFESSOR ZECKWEHR: I never heard of the method of playing from the wrist. All musicians play from the knuckle-joints, keeping perfectly quiet wrists.

DR. SEILER: Many musicians play from the wrist, and by that motion harshness is done away with and greater flexibility attained.

DR. BLACKWOOD: In organ-playing lateral movement of the fingers is necessary as well as extension. Does the operation increase the abduction and adduction movements? Experience has shown me the advantage of such mobility, particularly when the same hand is occupied in playing chords on two different manuals at one time, as, for instance, the 1st, 3d, and 5th on the great and choir.

DR. FORBES, in closing the discussion, said: In regard to the scar, I examined one of the patients to-day, and the scar could be scarcely seen. It should be distinctly understood that the cut necessary for the operation is but little longer than the width of a match. By means of a blunt knife to cut the tendon, and making the tendon tense, nothing else need be cut. From the first I performed this operation with a tenotome, but I received a letter from a gentleman at a distance, who said he had cut his own tendons with a razor. Dr. Willard spoke of cutting the dorsal interosseous muscle. If he does not carry the incision beneath the investing

[1] See page 601 of this number of the JOURNAL.

sheath he will not touch the muscle. You *may* cut the nerve to be found here next to the skin, but a dull knife avoids this by *shoving* the nerve before it. Dr. Allen spoke of encountering membranous bands on the tendons. I would cut tendons and bands at once. The patient should play at once on the piano after the operation, and if any bands remain they should be cut by reintroducing the knife. Both tendons are cut at one sitting. Dr. O'Hara was struck by the absence of the mention of women, considering their great activity as pianists. In fact, one patient alluded to was a woman. It may be that their joints partake of the greater mobility of their nature, and are less rigid. I have certainly found that these ligaments do not obstruct their playing on the piano so much as in men.

If the principle in music depends on the equality of sound, and these bands interfere with the development of this equality, I see no reason why they should not be severed.

This operation, of course, cannot lessen lateral motion.

As to elongation of tendons, this can be only by nutritive change. There is no elasticity in white fibrous tissue; sometimes it appears to elongate, but this is merely by lateral movement of fibres. This rigidity is the greatest value of white fibrous tissue.

In regard to Wickerscheimer's fluid, I have had a great deal of difficulty in its use, and thought he used some other ingredient in that imported, not mentioned when he sold his secret to the naval officers representing the United States Government. If, however, it is slowly injected in the preparation previously immersed in water, and then immersed in the prepared fluid and kept entirely immersed, sometimes it does well. The best quality of glycerine should be used.

CLINICAL SOCIETY OF THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

Stated Meeting held December 6, 1884. Dr. Thomas E. Satterthwaite in the chair.

Dr. E. L. Partridge opened the discussion upon

ERYSIPELAS,

the subject of the evening, as follows: Erysipelas, like the exanthemata, is infectious and epidemic; it has a period of incubation, prodromata, and a definite course, but on the other hand it is less contagious than any exanthem, and recurs with greater frequency, in these points resembling diphtheria and septicæmia. It is not interchangeable with the exanthemata or diphtheria, but may possibly be with septicæmia and puerperal fever, and perhaps with typhus. In 1838 erysipelas and typhus fever had existed together in an English hospital, and apparently were related. The relation of puerperal fever may perhaps be shown by the not uncommon case of the puerperal woman, who, contracting septicæmia, dies soon after childbirth, while the child dies of a distinctly phlegmonous erysipelas. It is probably never of neurotic origin, nor is it always necessary for it to be preceded by traumatism; there is undoubtedly an idiopathic form in which the poison gains access, in all probability through the respiratory tract. Of this latter view, however, we have no absolute proof, and the view which insists upon the necessity of an abrasion is therefore entitled to respect. The disease is probably spread through the lymphatics, and it has been shown by Billroth that it is possible for it to be thus conveyed to the pleura or meninges, and we may have inflammation of these tissues as a complicating factor in the disease. A predisposing cause may probably be found in a sluggish condition of wounded parts, as shown by flabby grayish granulation and scanty secretion, as well as in constitutional disease which impairs the venous return, as in disease of the liver, kidney, and heart.

The mortality of erysipelas was found to be greater in the winter than in the summer, being increased by contaminated atmosphere; to be greater in the very young or very old than in the middle aged; greater if the disease arose in the vicinity of wounds, and especially greater if there was any coexisting disease of heart or kidneys.

The best treatment was probably to rely upon general support and stimulation and to treat constitutional symptoms as they arose. A saline cathartic may be given with local depletion to relieve the tension when great, and quinine when the temperature runs high. It is very doubtful whether specific treatment or so-called abortive measures are of any use in limiting the disease.

Dr. D. B. St. John Roosa was inclined to think, possibly from his surgical education, that erysipelas is always traumatic in its origin. He did not believe that erysipelas could be generated on a sound skin. He believed that every eczematous spot and every lesion of the mucous membrane in persons in hospital life, or in delicate persons everywhere, should be, if possible, healed. He considered the poor ventilation common during the winter months as one of the causes of the prevalence of the disease during that season rather than the low temperature. In his experience cold did not produce the disease, but he thought he traumatism of a high wind blowing upon the face a very efficient cause. He considered the antipyretic use of quinine as useless and dangerous; that the dilatation that precedes the contraction of the blood-vessels by quinine does much harm. He recalled a case in which the temperature fell from 104° F. to below normal under no other drug than the tincture of the chloride of iron. He would use no medicine except a purgative, when necessary, but would rely upon good air, good food, stimulation, and attention to the comfort of the patient; locally he would use the lead and opium wash. The most disagreeable treatment that he has found is that with white paint.

Dr. W. O. Moore said that erysipelas was rarely a cause of eye trouble, or at least the connection was not, as a rule, made out, although we do meet with two forms of intra-ocular disease directly traceable to the poison of erysipelas, especially when facial. The first is a thrombosis of the retinal vessels, due to a direct propagation of the inflammation along the walls of the vessels, causing finally an obliteration of their calibre, or it may also be due in part to compression of the central retinal artery by the products of inflammation around the optic nerve and orbit. It is rare that one has the opportunity of seeing these cases during the acute erysipelatous period. "Since Knapp's paper, read in the early part of this year, I have anxiously looked for such a case, and at last, on August 6th, I saw one with the following history: H. C., male, aged thirty-nine, had received a slight cut, while being

shaved, on the right side of face. This soon developed into the ordinary form of acute erysipelas, in three days spreading over the entire face, though most marked upon the right side. The eyelids were moderately swollen, but no protrusion of the eye was noticed. The erysipelas did not yield promptly. Ten days after it commenced, on opening his eyelids, the patient noticed that his vision was impaired, although to outward appearances the eye was normal. On the fourteenth day I saw him, and on ophthalmoscopic examination found much the same appearances in the fundus as seen in the Coggin's and Knapp cases, namely: right eye, media clear; optic disk, outline clear, but substance milky, as was also the retina near the nerve; the vessels were distorted and tortuous; one small hæmorrhage into the retina towards the periphery of the fundus; the arteries were smaller than normal, and carried less blood; vision $\frac{1}{200}$. One week later the eyelids were well open; eye clear and bright; pupil moderately dilated; vision same as before; optic nerve more white; retina less milky; vessels smaller, looking as though no blood entered them; hæmorrhage previously noticed absorbing; one of the vessels looks like a white cord. In two months the patient was totally blind in the right eye, the other remaining in good condition. The only change in fundus appearance is in the optic nerve, which is white and atrophic, with only a few vessels containing any blood, the others being apparently empty. The second picture we see is the last stage of the disease, where the patient comes, months after the erpsipelas, with the ordinary white atrophy of the optic nerve. In looking over records of atrophy where a probable cause is given I find out of 200 cases only one where erysipelas was supposed to have a bearing. This percentage is, I think, too high."

Dr. David Coggin, of Salem, Mass., in the Transactions of the American Ophthalmological Society, 1879, reports a case of Ischæmia of Retinal Vessels of both Eyes after Facial Erysipelas. His idea was that the erysipelatous inflammation was propagated under the capsule to the optic nerve, where it exercised enough pressure to retard the circulation in the retinal vessels, and thus caused thrombus, or by thrombosis due to extension of the inflammation to the vessels themselves. The patient never recovered his vision.

Dr. A. Carl, in Zeheuder's *Monatsblättern für Augenheilkunde*, April, 1884, reports a case of Blindness from Erysipelas. Erysipelas began at the tip of the nose, then extended to the face. Fifteen days from the beginning of the disease R. E. became blind, with protrusion and immobility of the globe. Dr. Carl saw the patient seven weeks after the blindness came on, and found the media clear; V. = O; optic nerve outlines clear; disk milky and opaque; retinal vessels reduced in number, partially filled with blood, and partly reduced to white cords. Four months after blindness appeared complete atrophy of the optic nerve was noticed, and some of the arteries had entirely disappeared. The L. E. was in a normal state.

Dr. H. Knapp, in a paper read before the New York County Medical Society, March 24, 1884, says: First. Blindness was produced by compression of the central retinal vessels and thrombosis of the retinal veins. Second. No neuro-retinitis seen by the ophthalmoscope, but the successive stages of a thrombosis. Third. The white segments in the veins and arteries were whites thrombi, and not hypertrophy of the walls of the vessel.

DR. SENECA D. POWELL considered that the progress of antiseptic surgery during the past few years had done much to limit the spread of erysipelas. He did not consider that idiopathic erysipelas, or erysipelas without traumatism, was of uncommon occurrence, especially upon the face. It differed from traumatic varieties in not being contagious. The speaker had seen a case where erysipelas had set in after amputation of the breast, beginning about the wound and creeping down the left arm, returning up the arm, around the neck, down the other arm, then back across the neck, and again down the left arm, where it ceased. He was in the habit, if the patient had a full bounding pulse, of giving liq. ammon. acetat. ʒi.–ʒiv., spts. æth. nit. ʒi.–ʒiv., and tr. aconit. rad., gtt. i.–iij., q. 2 h. He used iron only in the idiopathic variety, employing a tincture made from the black oxide of iron three parts, hydrochloric acid ten parts, and alcohol thirty parts, with no water, instead of the officinal tincture, which contains both nitric acid and water. When in either variety the patient began to show signs of debility he always gives alcohol freely. Locally he considered the lead and opium wash applied hot, and the compresses covered with oiled silk, or, if this did not relieve the inflammation, heat applied by means of the hot bran bags, as the best applications.

DR. C. A. VON RAMDOHR said that in his opinion erysipelas depended upon a peculiar coccus which, if introduced into the circulation of a puerperal woman, might give rise to erysipelas, puerperal fever, or peritonitis, and therefore prophylaxis was a very important matter. The question of how long a physician should wait after seeing a case of septicæmia, pyæmia, or erysipelas, before attending a confinement case, could be answered by the remark, "If a physician knows what disinfection is he may go at once, if not he should give up attendance altogether." He made it a rule whenever he had seen a case of erysipelas to make a complete change of clothing, take an entire bath, and to particularly disinfect his beard, hair, and hands.

After this process he had attended confinements without any unhappy result. He made it a rule, however, not to examine very frequently after making out the presentation, but put the hand into the vagina as seldom as possible. He had seen the progress of the erysipelatous blush apparently checked by the injection of a three per cent. solution of carbolic acid into the sound tissue near the margin. Sixteen injections were used, and though very much reduced at the time the patient recovered.

DR. W. M. LESZYNSKY said that during the past week he had a case of facial erysipelas, in which the compound tincture of benzoin had seemed to have a good effect when locally applied. He had also seen another case in which the injection of a two per cent. solution, in different spots about the line of demarkation, had seemed to have a beneficial effect. He thought that in many cases where the recovery from a supposed erysipelas was very rapid the disease might have been, in reality, a dermatitis, and that the high temperature of erysipelas should have been present to establish a trustworthy diagnosis.

(To be concluded.)

— A remarkable variation of temperature occurred in Boston on the 21st inst., from —1.2° F. to +54.2° F., the range being 55.4° F. within twenty-four hours.

NEW YORK ACADEMY OF MEDICINE.

REPORT OF THE COMMITTEE ON ETHICS ON A "CHARGE AGAINST A FELLOW."

AT the meeting held December 4th it was announced that a charge had been made against a Fellow, and had been referred, according to rule, to the Committee on Medical Ethics. At the meeting of December 18th this committee, of which Dr. Andrew H. Smith is chairman, made their report, the First Vice-President, Dr. Robert F. Weir, presiding. The charge was made against the President, Dr. Fordyce Barker, by six Fellows of the Academy, that he had violated Section Third of the Fourteenth Article of the By-Laws by "committing an act which unfavorably affects the character of the medical profession."

Specification 1 was as follows: On or about January 4, 1854, or at some time later than January 4, 1854, the said Fordyce Barker did, with his own hand, inscribe in the signature book of the Academy the statement that he was a graduate in medicine of Paris of the date of 1844, the said Fordyce Barker not being at that time or at any subsequent time a graduate of Paris.

The other specifications made similar charges for different dates.

As the charges had already been made public the matter was disposed of in open session.

DR. SMITH, chairman of the committee, proceeded with the report, which took up the specifications in regular order.

As to the first, an investigation of the signature-book of the Academy showed that the entry, "and Paris, 1844," after Dr. Barker's name was in a different ink from the rest of the writing, and had evidently been written over an erasure; a fact to which the accusers made no allusion. It was manifestly impossible that Dr. Barker should have inscribed his name and the source of his degree in 1854, since the book was not in existence until the year 1862. Before that time such records were kept on loose slips, and there was at the present time in the possession of the Academy Dr. Barker's original application for membership, in which he stated that he had received the degree of M. D. from Bowdoin College, Maine, in 1841; no mention whatever being made of his being a graduate of medicine of Paris. Furthermore, Dr. Barker had always stated that he never knew that a diploma had been granted him in Paris until 1861.

As to Specification 2, Dr. Barker admitted that he had inadvertently given the year 1844 as the date of his Paris diploma instead of 1845.

In support of their statement that Dr. Barker had never received a diploma in Paris the accusers presented communications from a M. Clemenceau, who was said to be the secretary of the Paris Faculty of Medicine, a M. Chevallier, and others, to the effect that the tables of theses from 1840 to 1845, inclusive, had been looked through, that all the papers, complete and incomplete, of doctors, and even of officers of health, of these six years had been examined, without the name of Dr. Barker being found, and that without defending a thesis no one could become a Doctor of Medicine of Paris. They also stated that another search of the archives and of the library of the Faculty of Medicine had revealed that no trace of the medical studies of Dr. Barker in Paris between the years 1840 and 1870 existed, and that it was not possible that a foreigner should have received a diploma of Doctor of Medicine unless his name were inscribed in the archives. Having read the translations of these reports, Dr. Smith remarked that he would say in passing that only that afternoon there had been placed in his hands a copy of the *Almanac Générale de Médicine* which contained the official list of the Faculty of Medicine of Paris for 1844, and that he had searched in vain in it for the name of either M. Clemenceau or M. Chevallier.

The defense of Dr. Barker, the report continued, consisted in a clear and dispassionate statement in which the following points were maintained: That in 1845, at the suggestion of friends in Paris who were members of the Faculty, he underwent partial examinations for a degree from the School of Medicine; that his studies and examinations were interrupted by his being called home by the alarming illness of his wife's mother; that while awaiting a steamer in which to return he received a letter from Professor Orfila, Dean of the Faculty, informing him that a diploma would be granted him at some date in the near future; that he wrote a reply to this note relinquishing his claim to the diploma, as he could not reply to the necessary conditions; that sixteen years afterward, in 1861, not having in the mean time heard anything about the diploma, he was dining in Paris with M. Trousseau, in company with the Minister of Public Instruction, when Trousseau publicly referred to his (Dr. Barker's) being a graduate of Paris; that he immediately disclaimed the title, and related the facts above stated; that Trousseau affirmed that he knew that a diploma had been made out for Barker, as he himself had taken special interest in it, and as this document must be somewhere in the Department of the Minister of Public Instruction he appealed to that officer, who was present, to have it searched for; that a few days later, on returning from a temporary absence from Paris, Dr. Barker found at his hotel a roll, addressed to M. Trousseau and marked as coming from the Minister of Public Instruction, which contained his diploma from the School of Medicine in Paris, dated in 1845; that on his return home he showed this diploma to a number of friends gathered at his house to welcome him on the evening of his arrival in New York, two of whom were still living and remembered the occurrence; and that some years later it was discovered that this diploma, together with all his diplomas received prior to 1862, was lost, presumably on the occasion of his removal to his house on Madison Avenue.

When Dr. Barker heard of the present charges it occurred to him that he had shown his Paris diploma to a number of friends gathered to meet him on the occasion of his return from Europe in the autumn of 1861, and as Drs. Edwin H. Davis and R. Ogden Doremus were the only ones that he could remember who were still living, he wrote to each of them, without mentioning why he wished the information, to inquire if they remembered seeing the diploma and could recall any of the circumstances connected with his showing it to them. The replies of these gentlemen, together with the notes of inquiry to them from Dr. Barker, accompanied the statement of the latter, and were read by Dr. Smith. Both remembered seeing the diploma perfectly well, and also a number of the circumstances of the occasion when it was shown. Dr. Davis mentioned that among those who were present

were Dr. Doremus and Dr. Charles Budd; that the diploma was dated in 1844 or 1845; that Dr. Barker explained how it was that he had been so long in receiving it, though he could not now recall the explanation; that the time of his seeing the diploma was in 1861, as Dr. Barker had commented on the strange manner in which it impressed him to meet a regiment on its way to the seat of war as he was coming up Broadway on his way from the steamer; that he had examined the diploma with especial care, as he was at that time connected with the old New York Medical College, and had much to do with getting up diplomas, and that he remembered seeing Orfila's name signed to it and Trousseau's name on the back. Dr. Doremus wrote that he could fix the date because the battle of Bull Run and the birth of the only child of his who had not been brought into the world by Dr. Barker had both occurred during the summer, while Dr. Barker was away. He was struck with the name of Orfila on the diploma, because he was so familiar with it in his toxicological studies. Dr. Barker had pointed out the date, 1845, explaining how that had happened, and telling of Trousseau's kindness in recovering the diploma for him. He also remembered that Dr. Budd had made some facetious remarks in regard to the way in which the diploma might be used.

The report of the committee was concluded in the following words: "This statement from a man of the high character of Dr. Barker, coupled with the fact that he did not claim that he had a Paris degree until after his return from Paris in 1861, when he had been already twenty years in practice, during sixteen of which he had been a professor, and when he had been the recipient of many professional honors, might well be deemed a sufficient answer to mere negative evidence, depending for its validity upon an assumption that a record cannot be incomplete. Added to this is the evidence of two unimpeachable witnesses. The committee has therefore decided unanimously that the charges are not sustained."

The report of the committee was adopted by a unanimous vote.

— A man went to Bristol, Eng., says a daily contemporary, for a few days to stay with some people, and especially to visit a lunatic asylum in the neighborhood, where a large concert for the benefit of the inmates was given. The visitor found the audience, with very few exceptions, intelligent, appreciative, and, to all outward appearance, perfectly sane. The person who sat next to him conversed so delightfully that he felt compelled to remark: "I beg your pardon, but you are surely not a — a — resident here?" To which the stranger replied meekly: "Yes, I am." But insisted the visitor, "You are not — you cannot be — the least mentally afflicted?" And the other replied: "Well, I have an inconceivable predilection. In fact, you see this piece of chalk. Wherever I go I can't resist the temptation to write bad language on the walls. My keeper has nothing to do but walk behind me with a wet sponge and rub it out, but he has a hard time, for I write very rapidly. I was three damns ahead up to 7.30, and I have just written 'hell' five times on your back!"

Medical and Surgical Journal.

THURSDAY, DECEMBER 25, 1884.

A Journal of Medicine, Surgery, and Allied Sciences, published weekly. Price, 15 cents a number; $5.00 a year, including postage.

SPECIAL NOTICE. — Messrs. Houghton, Mifflin & Co. desire to announce that arrangements have been made to transfer the publication of the "Boston Medical and Surgical Journal" to Messrs. Cupples, Upham & Co., on the first of January, and they wish to close up the accounts of the Journal as soon as possible.

They therefore earnestly request all subscribers to the Journal who have not paid their subscriptions up to January, 1885, to remit without delay the sums due on this account to

HOUGHTON, MIFFLIN & CO.,
4 Park Street, Boston, Mass.

ANNUS MEDICUS, MDCCCLXXXIV.,

Or rather Annus Domini 1884, but Annus Medicus — what? In a sense the latter expression may seem to be synonymous with Annus Salutis Humanæ, but for the numeral really appropriate to the medical year we should rather look to the Hebrew than to the Christian calendar. Annus Medicus I. was probably Annus Mundi I., but for the number of the current medical year we will allow each reader to make his own calculation. Meantime, following a former custom of this journal, we will in this closing number of the year briefly recapitulate some of its leading events.

The prominent point of interest for the past year for medical men has unquestionably been the invasion of Europe by cholera. The first case was reported to have presented itself June 14th on board a French man-of-war which had been lying at the naval yard at Toulon for fifteen months. The disease ravaged Toulon, attacked Marseilles, and spread to a number of smaller towns and villages throughout Southern France. Italy was invaded by Leghorn and Spezzia in spite of elaborate quarantine proclamations, the clothing of Italian workmen returning from France being very efficacious in spreading the poison, — in fact it could not have been more effective in this way if it had been baled rags!

Naples was the greatest sufferer, about seven thousand deaths taking place in a population of half a million. Cholera found its way into Spain, but its victims there, though widely scattered, were comparatively insignificant in numbers. Some cases of cholera were reported at Paris and neighboring towns early in the summer without being officially authenticated. Toward the end of October there was no doubt about the presence of the pest at Nantes, Montreuil, St. Nazaire, Yport, and other places in the northern departments; and by November 5th, the fact that cholera had entered Paris was officially recognized. The epidemic in Paris was a short and mild one, and now at the end of the year little more is said about it.

The number of cases in France and Italy, since the middle of June may be stated at not far from 25,000, and the mortality at something under fifty per cent.

The comma bacillus of Koch has excited and continues to excite much discussion and experimentation.

Rietsch and Nicati, and subsequently Koch himself, announce that they have supplied the missing link of inoculation; but, on the other hand, a skeptical Frenchman has swallowed the bacilli with impunity, and an English observer (we believe incorrectly) is persuaded that it exists in all saliva. We prefer to await the lapse of another year before attempting to estimate the exact relation of this microbe to cholera. An English commission, consisting of Drs. Klein and Heneage Gibbes, is now at work on the question in Bombay, and their official report may be awaited for additional light. We understand that, thus far, although recognizing the bacillus as a distinct microbe accompanying cholera, they have been unable to establish any pathogenic relation to it.

Let us hope that a year hence our exact knowledge of cholera may be enlarged, but only as an abstract disease-problem.

Considerable agitation has been caused in educational and medical circles in England by the open criticism offered by a number of medical men, notably by Mr. Crichton Browne, of the overpressure upon pupils in the public schools. Mr. Browne's paper called forth a rattling rejoinder from the Minister of Education, which was met in turn by further detailed evidence, that, to the minds of the medical public at least, seems to present quite a strong case. The matter is certainly one not to be settled by any flippant wordy war, and our English brethren will, it is to be hoped, in the interest of the great question of popular education, which is broader than any national limits, investigate calmly and dispassionately how far the demands of the present school system are in conflict with the true mental and physical welfare of the pupils.

In April the University of Edinburgh celebrated in a series of brilliant assemblies the completion of her three hundredth anniversary in a condition of material wealth and intellectual vigor promising well for a perpetuation of her existence for another three hundred years. Among the scientific men called to receive academic degrees on that occasion were several of our own countrymen.

During the summer a novel and interesting exhibition has been held at South Kensington, London, of articles relating to public and individual sanitation. "The Healtheries," as the buildings were dubbed by the public press, have been thronged during the whole season, and the undertaking has at least financially proved a successful venture. The scope allowed to exhibits has been a wide one, and improved methods for heating, lighting, ventilation, drainage, cooking and preserving food, dress, technical education, sanitary plans for the domicile and the workshop, and many other important subjects were illustrated. Moreover, those popular features were not omitted which serve to present instruction in an attractive form. Lectures on topics of interest were given by competent speakers, and the English people, as well as visitors from other countries, have had an opportunity never granted heretofore of becoming practically informed on many important subjects not usually well understood by the public.

The rescue of Lieutenant Greely and the few survivors of his party by the relief expedition under Commander Schley was one of the satisfactory achievements of the year. The capacity of the human frame to endure exposure to cold and insufficiency of food has been again illustrated. The readers of the JOURNAL were given the medical history of Greely's case from the time of his rescue till his restoration to health, as recorded by the surgeon in charge of him. Attention has been directed anew to the physical and mental effects of starvation, as well as to some phases of that dire experience which seems to have been forced upon the survivors, namely, anthropophagy.

The profession in Berlin has been considerably agitated over the appointment of Dr. Schweninger to the Medical Faculty of that university by the command of the Prime Minister, and over the protests of the other members of the body. A paternal government is often claimed as affording an especially favorable atmosphere for higher scientific culture. But paternity sometimes passes over into nepotism, and the illustrious grateful patient recompensed his attendant with a chair which he is universally admitted to be too small to fill, to say nothing of certain methods so strongly savoring of charlatanism that they look singularly incongruous with professional robes. Meantime, as the paternal government does not favor freedom of speech, medical opinion can speak in no louder or clearer tones than a suppressed growl, and Schweninger keeps his seat. That the honor is somewhat of a barren one, however, is shown by the fact that thus far not a single student has attended his clinic, and it remains for the autocrat to issue a ukase to the effect that students shall admire and seek after the new professor.

Among the therapeutic novelties of the year we may mention two, etherization by the rectum and cocaine. The former proceeding was brought to the attention of European and American physicians by Dr. Mollière, of Lyons. The advantages first anticipated from this method in economizing the amount of the anæsthetic were found to be counterbalanced by the impossibility of regulating the degree of anæsthesia and by the intestinal disturbance caused by the local action of the gas, so that the procedure has been generally relegated to those few cases in which inhalation is for some reason impracticable.

Cocaine was introduced, or, rather, was shown to be of practical utility as an anæsthetic by Dr. Koller, of Vienna. Its great value as a local anæsthetic upon the conjunctiva has been abundantly established, and experimentation with it in various forms of administration is now rife on every hand. With what permanent residue of good must be left to the chronicler of a future Annus Medicus.

The medical world has come to look with interest for those statements of the latest and best professional opinion upon various topics which are embodied in the endowed courses of lectures of which our English brethren enjoy several, and which, it is to be hoped, will some day, through the beneficence of some of the

wealthier members of the profession, become a regular institution of our own medical centres.

Among the more notable English productions of the year in this kind have been the following: —

The Lettsomian Lectures on Modern Operations for Cataract, by Mr. R. Brudenell Carter.

The Gulstonian Lectures on Neuroses of the Viscera, by Dr. T. Clifford Allbutt.

The Croonian Lectures on the Evolution and Dissolution of the Nervous System, by Dr. J. Hughlings Jackson.

The Lumleian Lectures on the Ætiology of Phthisis, by Dr. J. Andrew.

The Bradshawe Lecture on the Pathological Relations of the Absorbent System, by Dr. G. Hare Philipson.

The Bowman Lecture on the Relation of Certain Diseases of the Eye to Gout, by Mr. Jonathan Hutchinson.

Of other valuable courses of lectures we should mention that by Sir Henry Thompson on Some Important Points in Connection with the Surgery of the Urinary Organs.

The more important Societies met during the year as follows: —

The American Climatological Society held its initial meeting in Washington, May 3d to 5th.

The American Medical Association, at Washington, May 6th to 8th.

The American Laryngological Association, in New York, May 12th to 14th.

The Massachusetts Medical Society, in Boston, June 10th to 11th.

The American Neurological Society, at New York, June 18th to 20th.

The British Medical Association, at Belfast, July 29th.

The International Medical Congress, at Copenhagen, August 10th to 16th.

The International Congress of Hygiene, at The Hague, August 21st.

The Canada Medical Association, at Montreal, August 25th to 27th.

The American Gynæcological Society, at Chicago, September 30th to October 2d.

The American Public Health Association, at St. Louis, October 14th to 17th.

GENERAL NECROLOGY FOR THE YEAR.

Dr. Elisha Harris, Secretary of the New York State Board of Health and Superintendent of Vital Statistics, died February 1st, aged sixty. During the war he was active in the organization and work of the United States Sanitary Commission, and since then has done much service in various official positions in connection with vital statistics and public health.

Dr. George Engelmann, of St. Louis, a prominent physician of that city, and for many years President of the St. Louis Academy of Medicine, died February 4th, aged seventy-six.

Dr. John Hutton Balfour, emeritus professor of medicine and botany in the University of Edinburgh, and author of a variety of books and articles on scientific topics and especially botany, died in February, aged seventy-six.

Dr. L. P. Yandell, of Louisville, Ky., editor of the *Louisville Medical News* and professor of the theory and practice of medicine in the University of Louisville, died in March, aged forty-seven.

Professor Reichert, late professor of anatomy in the University of Berlin, died, aged seventy-three.

Allen Thomson, M. D., F. R. S., etc., one of the most distinguished anatomists and embryologists of his time, died in London March 22, 1884, at the age of seventy-five. He was born in Edinburgh, and was at one time associated intimately in anatomical work with Dr. William Sharpey. He was professor of anatomy and physiology at different times in three of the four Scottish Universities, namely, Aberdeen, Edinburgh, and Glasgow, and was a voluminous writer. Perhaps that portion of his work most familiar to our readers is in connection with Quain's Anatomy, of which he edited the seventh and eighth editions. He received numerous academic honors, among them the degree of D. C. L. from Oxford.

Jean Baptiste Dumas, professor of chemistry at the Faculty of Sciences, the Faculty of Medicine, and the College of France, friend and disciple of Lavoisier, and member of the Académie Française, died at Cannes, whither he had gone for his health, April 17th, at the ripe age of eighty-four.

Charles Adolphe Wurtz, of Paris, an associate of Dumas, and an equally distinguished chemist, died in Paris, May 12th. He was a successor of Orfila and of Dumas in the professorship of chemistry, was Dean of the Faculty of Medicine and of the Academy of Sciences, and a fertile writer on chemical subjects.

Dr. Pliny A. Jewett, of New Haven, Conn., for twelve years professor of obstetrics in the Medical Department of Yale, and ex-President of the Connecticut State Medical Society, died April 10th, aged sixty-eight.

Dr. Moreau, of Paris, formerly connected with Bicêtre and La Salpétrière hospitals, and a somewhat noted alienist, died, aged eighty.

Dr. Willard Parker, of New York, died April 25th, at the age of eighty-four. He held professorships in anatomy and surgery at the Vermont, the Berkshire, and the Cincinnati Medical Colleges, and from 1839 was for thirty years Professor of Surgery in the College of Physicians and Surgeons of New York. At the end of this time he resigned this chair and was given that of clinical surgery. His contributions were numerous to public health as well as to surgical science, in which field he devised a number of operative procedures. He was an honorary member of the Massachusetts Medical Society.

Prof. Samuel D. Gross, of the Jefferson Medical College of Philadelphia, one of the most illustrious American surgeons of his time, died May 6th, at an advanced age. His contributions to surgical literature were numerous, among the most widely known being his System of Surgery, of which he had just com-

pleted with the aid of his son a new and much enlarged edition at the time of his death. In 1880 he received the degree of LL. D. from the University of Cambridge, England. News of his death was received during the session of the American Medical Association, and was announced to that body, of which he had been a former president.

Dr. Alexander Tweedie, of Edinburgh, died May 30th at the age of ninety. He was the originator of the Cyclopædia of Practical Medicine, which covered with considerable fullness the ordinary range of medical subjects, and also edited the Library of Medicine which appeared in 1840.

Sir Erasmus Wilson, a well-known authority and author on dermatology, died in England, August 7th, at the age of seventy-five. He had been President of the Royal College of Surgeons. He was possessed of large wealth, which he used liberally during his lifetime for public charities. He endowed a chair of Dermatology in the College of Surgeons, of which he was himself the first incumbent. He also founded the chair of Pathology at Aberdeen, and left a residuary legacy to the College of Surgeons which will probably amount to $900,000.

Joseph Janvier Woodward, Surgeon, U. S. A., an original worker in microscopy and micro-photography, and a collaborator with Dr. F. N. Otis upon the early volumes of the Medical and Surgical History of the War of the Rebellion, died August 17th, aged fifty-two.

Dr. Julius Cohnheim, in early life an associate of Virchow, at Berlin, later professor at Kiel and at Breslau, and finally at Leipsic, best known for his researches on the pathology of inflammation, died at Leipsic, August 14th, at the age of forty-five.

John Netten Radcliffe, an able and industrious laborer in the field of public health in England, died in September. In familiarity with epidemiology, especially that of cholera, he was probably equaled by none of his contemporaries. A report on this subject to the Privy Council in 1865 was the first of a series of such papers which gave an immense amount of information as to the place of origin and the progress of various epidemics; the last of these reports was issued in 1881. He was made President of the Epidemiological Society in 1875. His experience would doubtless have been of great value in the epidemic of the present year, had he been spared.

Dr. Jacob H. Stewart, a prominent physician of St. Paul, Minn., formerly mayor of that city, member of Congress, and surveyor-general of Minnesota under President Hayes, died August 25th, aged fifty-six.

Dr. Robert E. Rogers, Professor of Chemistry in the Jefferson Medical College of Philadelphia, died September 6th, aged seventy. He had filled a similar professional chair in the University of Pennsylvania.

Prof. Luigi Somma, of Naples, founder and editor of *Archivio di Patologia Infantile*, was stricken down by cholera during its invasion of Naples, and died at the post of duty, September, 19th.

Professor Jäger, of Vienna, renowned as an ophthalmologist, died during the summer.

Dr. Herman von Zeissl, a contemporary and coworker with Skoda, Hebra, and Rokitansky, and an eminent syphilographer and teacher of Vienna, died September 23d, aged sixty-seven.

Dr. Sulpice Antoine Fauvel died in Paris, November 5th, at the age of seventy-one. He was for many years inspector-general of the Sanitary Department of France, and had represented his country at two international sanitary congresses.

Dr. Frederick A. Mahomed, a student and writer in the domain of what might be called transcendental pathology, died of typhoid fever November 22d, in the 36th year of his age. His first elaborate work was on the sphygmograph, he made several contributions to the pathology of Bright's disease, and during the past summer he was engaged in organizing the anthropometrical laboratory at the Health Exhibition. He was one of the most active promoters of "collective investigation."

Prof. J. B. Fonssagrives, a well known French writer on medical and hygienic subjects, died of cholera.

NECROLOGY OF THE MASSACHUSETTS MEDICAL SOCIETY. 1884.

George Carlisle Lawrence, M. D., of North Adams, died January 6th, aged sixty-three.

Joshua Jewett Johnson, M. D., of Northborough, died January 29th, aged seventy-four years.

Almon Nelson Allen, M. D., of Pittsfield, died February 6th, aged sixty-three.

Noble Bennett Pickett, M. D., of Great Barrington, died February 5th, aged eighty-three.

Albert Faxon Eastman, M. D., of Abington, died February 13th, aged forty-one.

Henry Lyman Sabin, M. D., of Williamstown, died February 24th, aged eighty-three.

Michael Roberts, M. D., of Lawrence, died February 10th, aged fifty-six.

Morris Spofford, M. D., of Groveland, died March 7th, aged fifty-five.

George Hooker, M. D., of Longmeadow, died March 14th, aged ninety.

Wilbur Fiske Sanborn, M. D., of North Sandwich, N. H., died March 19th, aged thirty-four.

William Henry Campbell, M. D., of Roxbury, died April 24th, aged fifty-two.

Willard Parker, M. D., of New York, died April 25th, aged eighty-four.

Edgar O'Meara Fowler, M. D., of Danvers, died May 1st, aged thirty-one.

Charles Hosea Hildreth, M. D., of Gloucester, died May 18th, aged fifty-eight.

William Lawrence Sprague, M. D., of Boston, died June 22d, aged thirty-four.

Benjamin Franklin Wing, M. D., of Jamaica Plain, died August 1st, aged seventy-nine.

Abel Bryant Adams, M. D., of Lexington, died August 13th, aged seventy-three.

John Homer Dix, M. D., of Boston, died August 25th, aged seventy-two.

Frank Abner Langworthy, M. D., of Lakewood, N. J., died in California, August 31st, aged thirty-four.

Howard Franklin Damon, M. D., of Boston, died September 17th, aged fifty-two.

Luther Clark, M. D., of Boston, died September 26th, aged seventy-four.

Charles Morris Duncan, M. D., of Shelburne, died October 4th, aged seventy-six.

William Jackson Currier, M. D., of Lexington, died October 27th, aged sixty-nine.

Edward Jarvis, M. D., of Dorchester, died October 31st, aged eighty-one.

Nathan Savery Chamberlain, M. D., of Marlborough, died October 31st, aged thirty-nine.

Samuel Augustus Fisk, M. D., of Northampton, ex-President of the Massachusetts Medical Society, died November 16th, aged sixty-three.

Henry Austin Martin, M. D., of Roxbury, died December 7th, aged sixty.

THE TRIAL AND ACQUITTAL OF DR. FORDYCE BARKER BY THE NEW YORK ACADEMY OF MEDICINE.

THE trial last week of Dr. Fordyce Barker before the New York Academy of Medicine, of which he was President, for improperly claiming a Paris degree of Doctor in Medicine, was a sad business. We care very little for the evidence in the matter one way or the other. But the forcing of such an issue in such a manner against a professional brother of Dr. Barker's standing bears too plainly the impress of personal pique and spite. The profession of medicine can gain nothing from such performances.

This trial is to be regarded as a melancholy echo of the wrangle over the Code in New York last year. Whatever opinion we may entertain of the wisdom of the men who forced that foolish issue last year we are glad to be able to congratulate Dr. Barker heartily upon the handsome vindication he has received.

Hitherto the only good issue of the whole Code controversy which we have been able to detect was the formation of a State Medical Association which does really valuable medical work to the neglect of wire pulling and pipe laying for public popularity.

MEDICAL NOTES.

NEW YORK.

— The exercises of the sixteenth anniversary of the Presbyterian Hospital were held on Sunday evening, December 14th, at the West Presbyterian Church, when a sermon appropriate to the occasion was preached by the Rev. Dr. John R. Paxton, in the course of which he said: "We are indebted to the Jews for many things, for human law and their teachings of the sacredness of life, but not for hospitals. These are the sole creation of Christianity. The first hospital founded was in a little inn on the road from Jerusalem to Jericho, when the good Samaritan, as attending physician, poured oil into the wounds of the first patient, the man found upon the road-side. This hospital was but the beginning; but although insignificant, the idea had been born, the duty to aid our fellow-men recognized, though the means how to do it best were wanting." Since the last anniversary five beds have been endowed by the Presbyterian churches of New York at a cost of $25,000, and thirteen churches and chapels are now providing funds for additional beds, while a certain lady has promised to give $50,000 towards $150,000 that is needed for the erection of children's and accident wards if the rest of the amount is subscribed.

— The annual meeting of the State Charities Aid Association was held December 13th, when the Sub-Committee on Hospitals reported that they had prepared two plans: one for a village hospital, accompanied by an explanatory leaflet, and one for a model poor-house. An effort has been made by another committee to establish cooled-water fountains in crowded tenement-house districts. Reports from the Metropolitan Drinking Fountain Association in England, it was stated, show that these fountains supply a great want in such districts, and are the means of doing much good, diminishing sickness among children, and also lessening intemperance. A special Committee on the Insane, which was appointed last February, has prepared two pamphlets: one entitled A Summary of Legislation in England, and Condition of Lunatics in Scotland, and the other on the Training of Nurses for the Insane. This committee has secured the coöperation of the Bellevue Training School, and is now occupied in maturing a plan by which a certain number of women trained there as nurses for the sick may secure in one of the asylums a special training in the care of the insane. A fund of $1350 has also been contributed to be used in the training of such nurses.

— "Doctor Grattan," Dr. Hammond's second novel, has appeared, and in it the author is said to have availed himself of his experience in mental disorders to produce a number of romantic and surprising situations. In the meanwhile his "Lal" is being prepared for representation on the stage.

Correspondence.

LETTER FROM PARIS.

THE CHOLERA EPIDEMIC.

PARIS, *November* 22, 1884.

MR. EDITOR, — Believing that a short account of the recent epidemic of cholera, which has visited this city, may be of interest to some readers of the JOURNAL, I send you a brief description of what it came in my way to observe: —

I reached Paris October 20th. In Berlin, which I left, the weather had been cold with frequent drizzling rains, and a dull, dark, and dismal atmosphere. I was told that a somewhat similar state of things had also been present in France, although the weather was fine on my arrival. During the four weeks of my stay in this city there have been two rainy days, and two or three cloudy days. The weather during the remaining

time has been generally clear, and the temperature cool, the midday reading averaging perhaps 50° F. to 55° F.

The drainage of the greater part of the city seems to me excellent, the sewers are supplied with an abundance of water from the public fountains and other sources, and the mains are regularly opened in the streets or beneath the sidewalks for the purpose of additional flushing. I have never been able to detect any odor from the sewer openings, and in the houses where I have been there was not the slightest perceptible trace of sewer gas.

I did not go through the sewers, but a friend who traveled through some five miles of main or contributory sewers on October 25th described the condition of the sewage as very dilute, and except in a few localities at the junction of several trunk sewers there was no offensive odor. The telegraph system of Paris is also conveyed in the interior of the sewers, and one of the men constantly employed in repairs and new construction said that he had not been sick or in any way unpleasantly affected by the work in the sewers during five years of service.

In some limited districts of Paris the improved sewerage system has never been fully carried out, and one there sees still the old form of gutter near the sidewalk with more or less offensive and discolored contents. The older houses are also built in the shape of a square block inclosing a small court-yard, where the water supply for the entire building is located, and the drainage, except from the latrines, flows through the court-yard and under the main entrance to the street in an uncovered gutter. Here there may at times be noticed a somewhat offensive odor.

The food supply seems to be exceptionally good. I visited the great central market, "les Halles," at one o'clock in the morning. I could observe nothing in the least degree questionable in quality, and was struck by the absence of "second class" articles of food consumption. There is evidence of a rigorous inspection of all articles of food supply.

The water is of surface origin and is soft in quality, clear in appearance, and free from perceptible odor or taste. I believe the house service is generally by a supply tank, and not by direct flow from the mains. I have no knowledge of the milk supply further than the fact that in several places of pleasure resort there are stables in which cows are kept and visitors enter the stalls and for a small price receive a cup of milk warm from the cow. I tasted no milk which impressed me as bad, and saw no dirty milk.

Under these condition cholera appeared in the city, and after four or five days had assumed such proportions in the form of an epidemic that it was impossible to further conceal the fact of its existence. The first cases occurred in one of the poorest districts in the city, and were for a time confined to certain large tenement houses inhabited by rag pickers, and occupied in part as a depository or depot for rags of all kinds. The patients were without an exception those of intemperate and filthy habits, who were badly housed, insufficiently nourished, poorly clad, and much exposed to cold and wet. Many of the earlier cases died without treatment or were treated in their homes; but soon arrangements were adopted for the immediate transportation of cholera patients to the various hospitals where special isolated wards were devoted to their care. Removal from the patient's home was never made obligatory, nor was it considered necessary to place the infected houses in quarantine or to establish police supervision over the residents.

At this time no restriction was placed on travel between Paris and the southern parts of France.

For some days after the official announcement of the existence of an epidemic the disease increased in severity and extended from its point of first appearance to nearly every ward of the city. In nearly all instances some means of infection from previous cases could be traced, but in some cases it was not possible to discover the manner by which the disease had been acquired.

A volunteer medical service was at once established, and with the coöperation of the municipal sanitary board and the aid of the police, the city was thoroughly patrolled, and every offensive place either cleansed by the authorities or by the owners or occupants of the property. The smell of disinfectants was frequently noticeable, and the public streets and squares were, if possible, kept even more scrupulously clean than before. In many streets the gutters were constantly flushed by opening the hydrants, and the public urinals were disinfected. Each day the mayor issued an official bulletin in which the number of cases under treatment and the number of new cases was announced as well as the rate of dissemination of the disease by wards in the city. It was stated that the highest rate only amounted to one patient to 17,000 inhabitants. The cases were usually of a mild type, the mortality never to my knowledge exceeded thirty-three per cent. of the number of patients, and except in an outbreak which occurred in an asylum for the aged, supported by the scanty means of a few sisters of a religious order, there was no appearance of especial virulency about the epidemic. In this asylum the inmates who took the disease were, I believe, all above seventy years of age, and the mortality, as might have been expected, was relatively very high. Here also occurred the only instance of the entire epidemic in which a nurse or attendant was known to take the disease. One of the sisters who was constantly in the room devoted to cases of cholera is said to have taken the disease, and after two days died from it. With this single exception no instance was known in which cholera was directly communicated from the person of the patient to his attendants, or even to his surroundings.

As may be supposed, many persons then in Paris were much alarmed by the presence of cholera as well as by the apprehension that neighboring countries might establish quarantine against persons or commerce from French ports, and a general exodus of travelers and strangers at once took place.

It is estimated that within four days more than thirty thousand people crossed the channel to various ports in England, nearly all of whom came from Paris. The hotels became literally empty; many families who were established for the winter at once left the city, and a vast change was immediately noticeable in the clubs, thoroughfares, and fashionable restaurants. Strange to say, the resident inhabitants of Paris did not become in the least frightened, and no signs of a panic were at any time observable. The theatres were better filled during the weeks of cholera than during the weeks immediately preceding, and no change was noticeable in the behavior of the common people, that element which is generally most easily frightened by any unusual occurrence.

After about ten days of maximum severity the number of cases and the gravity of the disease became gradually diminished, until to-day the epidemic is at an end. Cases of so-called "choleraic" disease were reported for some days after the subsidence of the true cholera, but these were uniformly of mild character and ended in every instance by recovery.

The report of cases in the military establishments are very unsatisfactory, and are not taken into account, though there were doubtless a few cases in the barracks.

The reported treatment consisted in a general way in the moderate use of anodynes, the administration of stimulants, the application of external heat, and the nourishment of the patient by bland food in liquid form. In some cases nutrient enemata were employed, and the use of saline intravenous injections was also reported. No special mode of treatment has seemed to influence the disease in an appreciable manner. The favorable change in the epidemic and its final subsidence are generally referred to the lower temperature, and particularly to the frosts of the middle of November.

So far as I was able to observe, there is a far greater degree of confidence on the part of the medical profession in France, in the employment of prophylactic measures to prevent the occurrence or spread of cholera than in any method of treatment when the disease has once appeared. The low death-rate in the present epidemic is attributed wholly to the mild form of the disorder, and not to the advancement of our knowledge concerning the disease, or of improved methods of treatment.

The police were supplied with flannel bands for the abdomen, and were served a ration of grog and sometimes coffee during the night patrol. The municipal government made grants of money for the relief of the sufferers, and the gratuitous supply of disinfectants among the poorer classes.

There is no doubt that much cleansing was accomplished, and with this and the coming of cooler weather the disease abated and finally entirely disappeared.

In review, we have the outbreak of a limited epidemic in the centre of a large city, manifesting itself especially among rag pickers, and for a time apparently confined to them and to their habitat alone. Afterward the disease spread to a moderate extent and was reported from nearly every part of the city. The patients were almost without exception persons who were underfed, insufficiently protected, dissolute, and intemperate. To my knowledge not one stranger was attacked in the entire epidemic, and no English speaking person was known to suffer from the disease. But few residents of Paris left the city, and there was no appearance of fright, much less of panic to be observed. The disease is entirely quenched, and will doubtless not recur until the approach of warmer weather, when it will, in the opinion of most of those with whom I have spoken, again appear, and will far exceed the present epidemic both in the extent of its ravages and in severity. The disease has already been recognized in Nantes, in Yport, in Brussels, in Marseilles, in Toulon; it has crossed the border into northern Italy; it has invaded Spain, and has been reported in some other places. It is to be feared that the advent of spring will arouse the disorder anew, and that the entire west of Europe will be devastated by it.

The epidemic just ended has not contributed anything material in support of the theories of Professor Koch as to the origin or "Wesen" of cholera. I have not been able to find either here or in Berlin any ardent support for the claims of the comma bacillus as the cause or essential element of the disease. The importance of the bacillus of tubercle is generally conceded, and in Berlin I saw specimens which were made for purposes of diagnosis, thus showing that the presence of the organism is recognized as of practical value in daily routine; but the same authority spoke of the bacillus of cholera with some degree of distrust, and expressed the opinion of the profession as being that the bacillus is a concomitant but not clearly the cause of the disease. A French physician, to advance the cause of science, and to disprove the claims of Koch, prepared a portion of the dejections of a cholera patient containing the comma bacillus and swallowed the infection. He was ill for thirty-six hours with the symptoms of a gastro-intestinal catarrh with febrile action, etc., but then quickly recovered his usual health, and could perceive no detriment from this nauseating experiment. I do not need to add that the feeling in France is decidedly antagonistic to the claims of Professor Koch.

It is yet too early for the official report of the sanitary authorities and the medical department upon the recent epidemic in Paris, but I am led to believe that efforts are being made to utilize the presence of the disease as a study for guidance in the expected revival of the disorder in the near future. It is to be hoped that this important information may be published in advance of the threatened outbreak of cholera, but in the mean time every precaution is being employed to secure the best possible sanitary conditions, which must favor a mitigated severity in any epidemic disease.

Very truly yours,

ALBERT N. BLODGETT, M. D.

Miscellany.

THE INSTINCT OF THE SPHEX.

IN an article in the *Nineteenth Century* (September, 1884) on the Darwinian theory of instinct, Mr. G. J. Romanes speaks of the instinct of the sphex as being the most extraordinary known. This insect, which is of a wasp-like species, lays its eggs in a hole excavated in the ground. It then flies away and finds a spider, which it stings in the main nerve centre of the animal. This has the effect of paralyzing the spider without killing it. The sphex then carries the now motionless spider to its nursery and buries it with the eggs. When the eggs hatch out the grubs feed on the paralyzed prey, which is then still alive, and therefore quite fresh, although it has never been able to move since the time when it was buried. Satisfactory explanation of this instinct is difficult on either of the twofold bases of Mr. Darwin's theory of the origin of instinct, namely, natural selection and the "lapsing of intelligence." What is still more astonishing is that M. Fabre, the French entomologist who first noted these facts, has more recently discovered another species of sphex which preys upon the grasshopper. As the nervous system of the grasshopper is more elongated than that of the spider, the sphex in this case has to sting its victim in three successive nerve centres in order to cause paralysis. Again,

yet more recently, M. Fabre has discovered still another species of sphex which preys upon the caterpillar, in which case the animal must sting its victim in nine successive nerve centres. These last observations militate against the view that the sphex's sting being in the median line, and the spider's nerve centre being also in the median line, an accidental striking of the nerve centre might have been naturally favored in the first instances, and thus a basis have been supplied upon which natural selection could work.

REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 13, 1884.

WOMAN'S MILK FOR ANALYSIS.

THE undersigned is desirous of securing specimens of woman's milk for analysis, and begs the physicians of Boston to aid him in securing such. About two fluid ounces, — the more the better, — with a statement of the age of the woman, is desired, number of previous confinements, weight and food of child (if any food but breast milk is given), time of last nursing, from which breast sample is obtained. If any one will send word to the undersigned by mail a messenger will be sent for sample, and a copy of analysis furnished if desired.

H. C. HAVEN, M. D., 19 EXETER ST., BOSTON.
